"The fashionable colour of native cloths is blue, from the dye to which I now invite attention. The special commissioners who were sent into Yoruba in 1886 by the Government of Lagos saw repeatedly indigo under cultivation, and thus remarked on its use in the town of Ibadan, the estimated population of which is 150,000:—'Nearly all the people wearing blue cloths, the market-place was quite a study in blue.'

\* See this Journal, 1889, VII., 581.

"Within my own experience the industry proceeds extensively on the banks of the river Gambia, where indigo is called in Mandingo *karro*, and in Volof *n'ganyha*; in Yoruba, where *du* is given to it, and in Houssa, where it is known as *suini*, *suni*, or *zuni*, and the plant as *baba*. I give the following translation of a saying in Houssa in explanation of the interest taken in this industry. Schön's 'Dictionary of Houssa Language': 'The place where indigo is growing is good land; its leaves are small, and its seeds are small, but when it is ripe it turns red, and its mouth is pointed. My country is full of indigo and of cotton.'

"Along the valley of the Niger we come across the pure precipitate, the only form in which it is of marketable value.

"In the Gambia and in Yoruba we come across it in the form of balls of decomposed or fermented leaves of indigo plants, generally mixed with cow dung, and of no commercial value in foreign markets.

"The process of extraction of indigo is as follows:—In an earthenware pot of a capacity of 15 gallons, an extract by soaking the leaves is made, and fermentation allowed to follow when the liquid is poured off, and aerated so far as the rapid withdrawal and restoration from a height of 2 or 3 feet of a portion by means of a calabash or some other vessel will allow. Precipitation follows, and when all the dye matter (*fecula*) has sunk to the bottom of the pot the supernatant fluid is poured off. The precipitate, in the form of powder, is then mixed with a little gum and shaped into small balls, cones, &c.

"Dyeing process.—A cloth is soaked in the extract, unaerated, and then freely exposed to the air to dry; the process is repeated until the depth of colour desired is reached. When stripes or other shade designs are desired, patterns are secured by stitching up for process of dyeing portions on which colours are to be lighter. Such confined parts are less affected by the dye, and thus fancy is indulged in."—*Ibid*.

#### MINING INDUSTRY IN ITALY.

The Belgian Consul at Lucca in his last report says that according to the report of the Inspectorate of Mines, the number of mines in operation in Italy amounts to 662, and they employ 49,237 workmen; the total value of the ores extracted amounted to 53,591,771 frs. The provinces which have chiefly contributed to this industry are: Cagliari, where ores to the value of 17,824,000 frs. are extracted; Caltanissetta, where the production is valued at 13,501,985 frs.; Girgenti, which has produced 8,794,750 frs. worth; Tuscany, where the production has exceeded 5,500,000 frs.; and finally in each of the provinces of Arezzo, Grosseto, and Palermo, the value of the production amounted to nearly 2,500,000 frs. To these figures should be added a production of 4,255,372 frs. coming from some mines situated in other provinces.

The values of the principal ores extracted are as follows: iron ores, 2,292,454 frs.; copper ores, 1,100,065 frs.; zinc ores, 6,911,696 frs.; lead ores, 7,128,363 frs.; silver ores, 1,441,400 frs.; and gold ores, 5,327,651 frs.; mercury, 929,865 frs.; sulphur, 27,962,282 frs.; and boracic acid, 1,531,000 frs.—*Ibid*.

#### PRODUCTION OF ALANG-ALANG.

The *Bulletin du Musée Commercial* for January 25th says, that it has now been proved by various experiments conducted by experts, that the plant known as "alang-alang" (*Imperata arundinacea*) can be successfully used as material for the manufacture of paper. This plant grows in the Dutch Indies in boundless profusion, and requires no cultivation. Alang-alang, under advantageous circumstances, grows to the height of a metre and a half, and in Java the farmers are engaged in incessant efforts to keep it within bounds. It can be encouraged to grow anywhere in the humid atmosphere and rich soil of Java, and it is proposed to dedicate some waste lands in the suburbs of Batavia to the growth of alang-alang, a specimen of which has been sent to Brussels by the Belgian Consul-General at Batavia. —*Ibid*.

#### PAPERS INTERESTING TO TECHNOLOGISTS.

The following papers of interest will be found in the *Board of Trade Journal* for February:—

- "Production of Pine Apple Fibre in India," p. 190.
- "German Trade in the Straits Settlements," p. 199.
- "French and Foreign Competition in Senegal," p. 214.
- "Economic and Commercial Condition of Venezuela," p. 225.

#### FURTHER REPORT OF THE LABOUR CONCILIATION COMMITTEE TO THE COUNCIL OF THE LONDON CHAMBER OF COMMERCE.

*Adopted at a Special Meeting of the Council, and Council of Reference, of the London Chamber of Commerce, on Thursday, the 6th February 1890.*

Your committee has endeavoured to devise some practical methods for carrying out the scheme contained in the interim report provisionally adopted by the council on the 12th December.

The committee offers the following suggestions:—

- I. That a permanent body be constituted, to be called "The London Conciliation Board," which shall be affiliated to the London Chamber of Commerce, and that its composition shall be as follows, viz.:—
  - (a.) Twelve members representing capital or employers, to be elected by the council of the Chamber.
  - (b.) Twelve members representing labour, to be elected by the employed.
  - (c.) To these shall be added representatives from the separate trade conciliation committees as herein-after referred to.
  - (d.) The body thus constituted shall add to their number six other members, who from their position, authority, or experience, may be useful in promoting the objects of the London Conciliation Board, three to be appointed by the labour representatives on the Board, and three by the representatives of capital.
  - (e.) Four members, viz., the Lord Mayor of London, or some member of the corporation to be nominated by him, the Chairman of the London County Council, or some member of the council to be nominated by him, a representative of the London Trades Council, and a representative of a London labour organisation to be selected by the labour representatives on the Board.

The elections shall take place every three years, and the first election shall take place on the

II. The duties of the London Conciliation Board shall be as follows:—

- (a.) To promote amicable methods of settling labour disputes and the prevention of strikes and lock-outs generally, and also especially in the following methods:—
  1. They shall, in the first instance, invite both parties to the dispute to a friendly conference with each other; offering the rooms of the Chamber of Commerce as a convenient place of meeting. Members of the committee can be present at this conference, or otherwise, at the pleasure of the disputants.
  2. In the event of the disputants not being able to arrive at a settlement between themselves, they shall be invited to lay their respective cases before the committee, with a view to receiving their advice, mediation, or assistance. Or, should the disputants prefer it, the committee would assist them in selecting arbitrators, to whom the questions at issue might be submitted for decision.
  3. The utmost efforts of the committee shall, in the meantime, and in all cases, be exerted to prevent, if possible, the occurrence or continuance of a strike or lock-out until after all attempts at conciliation shall have been exhausted.

The London Conciliation Board shall not constitute itself a body of arbitrators except at the express desire of both parties to a dispute, to be signified in writing, but shall, in preference, should other methods of conciliation fail, offer to assist the disputants in the selection of arbitrators chosen either from its own body or otherwise. Any dispute coming before the Board shall, in the first instance, be referred to a conciliation committee of the particular trade to which the disputants belong, should such a committee have been formed and affiliated to the Chamber.

(b.) To collect information as to the wages paid and other conditions of labour prevailing in other places where trades or industries similar to those of London are carried on, and especially as regards localities either in the United Kingdom or abroad, where there is competition with the trade of London. Such information shall be especially placed at the disposal of any disputants who may seek the assistance of the London Conciliation Board.

III. The separate trade conciliation committees shall be composed of equal numbers of employers and of employed.

Each trade shall elect its own representatives, employers and employed voting separately for the election of their respective representatives. The number of members and the general rules of procedure shall be determined by each particular trade, subject to the approval of the London Conciliation Board.

The trade conciliation committees shall be affiliated to the London Chamber of Commerce, and shall be represented upon the London Conciliation Board. Any trade conciliation committee constituted as above, representing a body or trade in the metropolitan districts of more than 1,000 individuals, shall send two representatives to sit on the London Conciliation Board, one being an employer and the other an operative workman, each to be separately elected by employers and employed respectively. In the case of trade conciliation committees representing bodies or trades in the metropolitan districts smaller in number than 1,000 individuals, two or more such committees may unite together to elect joint representatives to the London Conciliation Board.

It shall be the duty of the trade conciliation committees to disown matters of contention in their respective trades; to endeavour amicably to arrange the same, and in general to promote the interests of their trade by discussion and mutual agreement. In the event of their not being able to arrange any particular dispute, they will refer the same to the London Conciliation Board, and in the meantime use their most strenuous endeavours to prevent any strike or lock-out until after the London Conciliation Board shall have exhausted all reasonable means of settlement.

They may, from time to time, consider and report to the London Conciliation Board upon any matter affecting the interests of their particular trade upon which it may be thought desirable to employ the action or influence of the London Chamber of Commerce as a body.

IV. The London Chamber of Commerce places its rooms at the disposition of the London Conciliation Board, and of the trade conciliation committees for holding their meetings. Any alterations in the rules and regulations of these bodies which may be from time to time proposed, shall be submitted for approval to the council of the Chamber.

V. The above regulations shall be subject to bye-laws, to be specially framed for the purpose, and which shall be open to amendment as required from time to time, on agreement between the council of the Chamber of Commerce and the London Conciliation Board.

Here follow the names of the Members of the Committee, January 31st, 1890.

#### *Explanatory Circular.*

The council has had particularly in view the necessity of giving capital and labour an equal representation, and equal voting power in the organisation of the proposed London Conciliation Board and committees.

Attention is specially called to the fact that this Board will not in itself be primarily, or of necessity, an arbitrating body, but its main object will be to bring the interested parties together for purposes of discussion and explanation at the earliest stage of any difficulty, with the view of preventing that difficulty reaching the acute stage of strike or lock-out, arbitration being only suggested in the last resort. It is hoped that the existence of a permanent board, composed of experienced and influential representatives of both capital and labour, to whom any difficulty arising in the labour market can be referred for discussion and consideration at an early period may, by intervention in a friendly and disinterested manner, enable points of difference to be settled by mutual consent, without any stoppage of trade. Should the difficulty, however, prove to be acute, or not one of a nature for settlement on general grounds, the Board will have powers to assist the disputants in nominating special arbitrators. One very important function of the Board will be to assist in promoting the formation of separate trade conciliation committees for the various industries carried on in the metropolis, to whom all disputes affecting those particular industries will in the first instance be referred.—*London Chamber of Commerce.*

#### THE CULTIVATION OF INDIGO IN CHINA.

*M. Jaues. Bull. de la Soc. d'Encour. pour l'Ind. Nat.*  
1889, 494.

Indigo is very largely cultivated in the province of Tchin-Kiang; each family requires the colour for dyeing their garments, the excess being sent to market. It is a plant which is very easily cultivated; it requires a special soil, as close as possible. When one month old the plants are replanted at distances of about 50 centimetres apart. Very little care is necessary, and in dry seasons the plants need not even be watered. When they attain a height of 60 centimetres they are cut down to the root and removed to pits dug in the earth or built of bricks of about 160 litres capacity. The roots throw out new shoots and yield a second crop. The plants are piled in the pits and covered with pure water and allowed to remain for some days, when a fermentation is set up. The operation may be hastened by the addition of a little chalk and by frequent agitation of the mass. At the end of the operation the indigo forms a thick blue layer at the bottom of the pit and it only requires drying to render it marketable.—*E. J. B.*

#### A NEW TIN ISLAND IN THE DUTCH INDIES.

The latest reports from Singkep, an island belonging to the Lingga group on the east coast of Sumatra, state that the prospects of finding permanent tin deposits there, similar to those in Banea and Biliton, are highly favourable. The concession for working these mines is in the hands of a private company.—*Industries.*

#### DYNAMITE IN SPAIN.

Although there is a large dynamite works at Bilbao, there is a good opening for another such establishment in the centre of Spain to supply the markets of Linares, the coal basin of Belnez, and the large and increasing mining districts in the provinces of Ciudad Real and Estremadura. The greatest inconvenience and delay are experienced in getting regular supplies in consequence of the difficulties of carriage. The dynamite from Bilbao must either pass through two systems of railways which are not on the best understanding with one another, or must go by sea to Seville, and thence a long distance overland. The Bilbao works are reported as having done a good business for many years.—*Ibid.*

#### WOOD-PULP MANUFACTURE IN SCANDINAVIA.

The erection of new wood-pulp manufactories continues, although the prospects cannot be said to be particularly bright. There will shortly be 54 wood-pulp manufactories at work in Norway, against the 50 working last year; and their probable production has been put at about 250,000 tons. The export during last year was about 190,000 tons, against

a production of 175,000 tons in the previous year. The above figures refer to "mechanical" wood-pulp. About 25,000 tons of "chemical" wood-pulp, of which rather more than half was wet, was also exported, being in excess of the figures for 1888. At the end of 1889 there were 15 manufactories of chemical pulp at work—11 sulphite and 4 soda cellulose works. Their production is estimated at 30,000 tons sulphite (wet) and 9,000 soda cellulose (dry). During last year chemical pulp maintained its price and commanded a ready sale—the exports being valued at about 200,000*l.* f.o.b. Norwegian port. The profits thereon were not equally satisfactory owing to the rise in raw materials. For mechanical wood-pulp the prices, which have been declining for the last 20 years, fell to 2*l.* 2*s.* 6*d.* per ton f.o.b. Hull. Attempts have been made to reduce and regulate production but without success. The value of mechanical pulp exported during 1889 amounted to about 450,000*l.* Increased production has given an impetus to the Scandinavian paper industry. In Sweden two or three paper manufactories have been formed of late, and in Norway existing ones have been materially extended. The effect of these extensions will be no doubt apparent before long.—*Ibid.*

#### PROGRESS OF THE BASIC OR THOMAS-GILCHRIST PROCESS DURING THE 12 MONTHS ENDING 31ST DECEMBER 1889.

The total make of steel and ingot iron from phosphoric pig during this period amounts to 2,274,552 tons, being an increase over the make for the previous 12 months of about 321,318 tons, and making the total production of basic steel to this date 10,845,000 tons.

It will be noticed that of the above-mentioned make of 2,274,552 tons, no fewer than 1,764,639 tons were ingot iron containing under 17 per cent. of carbon.

The makes of the various countries for the year ending 31st December 1888 and 31st December 1889, respectively, are as follows:—

	1889.		1888.	
	Total.	With under 17 per Cent. Carbon.	Total.	With under 17 per Cent. Carbon.
England .....	Tons. 493,919	Tons. 318,828	Tons. 408,594	Tons. 276,176
Germany, Luxemburg, and Austria .....	1,431,642	1,185,323	1,276,070	1,026,033
France .....	222,392	153,271	222,333	158,223
Belgium and other countries .....	76,599	71,217	46,237	32,360
	2,274,552	1,764,639	1,953,234	1,493,032

With this 2,274,552 tons of basic steel, were produced some 700,000 tons of slag (containing about 36 per cent. of phosphate of lime), most of which was used as a fertiliser.

#### THE STASSFURT INDUSTRY.

The Syndicate of the Alkali Works has issued its report of the sales during 1889. It appears that the deliveries of potassium chloride during the first half of 1889 amounted to 1,200,000 centners, and during the last half to 1,271,000 centners, as against 1,119,000 centners and 1,126,700 centners during the corresponding periods of 1888.—*Industries.*

#### WEIGHTS AND MEASURES ACT, COMMENCING 1ST JANUARY 1890.

The following clauses of the above Act are of importance:—

"Every weighing instrument used for trade shall be verified and stamped by an inspector of weights and measures, with a stamp of verification under this Act.

"Every person who, after the expiration of 12 months from the commencement of this Act, uses, or has in his possession for use for trade any weighing instrument not stamped as required by this Act, shall be liable to a fine not exceeding two pounds, or in the case of a second offence five pounds."

"In this Act, unless the context otherwise requires, weighing instruments includes scales, with the weights belonging thereto, scale-beams, balances, spring-balances, steelyards, weighing machines, and other instruments for weighing."

#### ALCOHOL IN THE INDUSTRIAL ARTS.

(Report for Year 1889 of United States Commissioner of Internal Revenue, p. 137.)

A Bill (H.R. 9051, Fiftieth Congress, First Session), having for its object the reduction of taxation and simplification of laws in relation to the collection of the revenue, has been printed and contains certain provisions relative to alcohol in the industrial arts. The Commissioner summarises its provisions as follows:—

Section 3 provides for bonded warehouses for storing the alcohol under internal revenue storekeepers and regulations.

Section 4 provides for the transfer of the alcohol from distillery warehouses to the bonded warehouses provided in section 3.

Section 5 provides for the removal of alcohol from the bonded warehouses to manufacturers' storerooms, to be there used in the industrial arts and in the manufacture of drugs and chemicals; proprietary articles and beverages being excepted. This section also provides certain regulations under which bonded warehouses and manufacturers' storerooms may be established.

Section 6 provides for the use of warehouse stamps.

Section 7 makes further provision for removals from warehouse to manufacturers' storerooms.

Section 8 gives revenue officers right of access to every part of the manufactory.

Section 9 provides for the methylation of alcohol in the bonded warehouses and for the use of methylated spirits in the arts and manufactures, for burning, and in the manufacture of compounds, except beverages. Bonds and returns may be exacted. Right of access to the revenue and penalties against fraud are provided.

Section 10 provides penalties for improper use of alcohol.

Section 11 provides for assessing taxes on spirits not used within three years, forbids use of methylated spirit within 600 ft. of a rectifier or distiller, and imposes penalties for breaches of the various provisions of the law and regulations.

The Commissioner in the main approves the Bill, but suggests that section 9 should be so modified as to provide that no methylated spirits shall be permitted on any premises in which distilling or rectifying is carried on, or where wines or spirits are kept for sale as beverages.

The Commissioner considers that since the object of demethylation is to secure a cheap alcoholic beverage, the importance of separating methylated spirits from all stocks of such beverages is very great; as is also that of keeping methylated spirit out of the hands of distillers and rectifiers who use stills.

The Commissioner, from data in his possession, estimates the quantity of alcohol likely to be used annually in the arts at about eight million gallons—and the additional expense required to carry these provisions into effect to be about 290,000 dols. per annum.—C. G. C.

#### COPPER ROASTING IN SPAIN.

About eighteen months ago the open-air calcination of copper ores in the province of Huelva was prohibited by a decree signed by Señor Albareda, then Home Secretary, now

Spanish ambassador in London. The order was to come into force on January 1, 1890. The Rio Tinto Company, as well as private copper-roasters, tried all they could to have the decree rescinded, urging, among other arguments, that the prohibition implied a breach of public faith, because calcination in the open air was practised in connexion with the copper works which had originally been made over by the Government to the various companies by whom the *explotacion* is now carried on. Having failed in their endeavour, the companies had no option but to discontinue the roasting of copper altogether, and dismiss the men who had hitherto been employed on this work. The number of those discharged in this way ranges, according to conflicting reports, from 500 to 1,500. Those are probably nearest the mark who set down at 2,000 the number of persons who have been deprived of their means of subsistence by the stoppage of the calcination. Some 250 of the discharged men proceeded to Huelva directly after New Year's Day, to lay their case before the Governor of the province, who was greatly surprised, for he had no idea that there were so many men wanted to make up the heaps. *La Epoca* relates that the spokesman of the roasters gave "the most excellent gentlemen" quite a lecture on the subject, pointing out to him that making up the heaps was only a small portion of the work; that the *teleros* must be minded and attended to, and that, before they are made up, the ores must be got out, picked, and worked up, all of which involves a numerous *personnel*; that there are, moreover, tools, machinery, and trains to which a number of men have to attend, and lots of other things to be done of which the Governor of Huelva was perfectly ignorant, although the copper mines are situated within his province. The latest intelligence shows that the Government have called upon the companies to employ the men in some other way, and that the companies have replied that they had no other work to offer to the men. Since the end of the ministerial crisis it has been expected that immediate means would be taken to relieve those whose living has been taken away from them by the ministerial decree.—*La Epoca*.

#### COMBINATION OF NITRATE MAKERS.

The following heads of agreement have been unanimously adopted by the nitrate companies in London, and telegraphed out to Iquique:—"It is agreed to form a combination of nitrate makers, representing not less than 90 per cent. of the whole, to restrict the production of nitrate to the estimated consumption, the amount of production to be fixed from time to time by the nitrate committee in London, in conjunction with the committee in Iquique. It is also agreed that, so far as the committee may be able to regulate the selling price of nitrate, such price shall not exceed 9*l.* 10*s.* per ton. A committee, consisting of seven members residing in Iquique, to be elected to ascertain the production and fix the quota to be assigned to each oficina. The quotas to be fixed on the following basis, and to be agreed to by all the members of the committee:—1. The basis of the calculation of the quotas for all oficinas completed on 1st January 1889 to be the actual quantity of nitrate produced by them during 1889. 2. Oficinas which were not completed by 1st January 1889, to have the option of selecting any three consecutive months' production, as shown by their books, as a basis of their annual production. 3. No new oficina to have any quota until actually producing. The new iodine combination formed on the coast to be approved so soon as the present nitrate combination be completed. The London committee to at once advise the iodine committee in Iquique that the late combination is to be continued until the new one can be put in force."—*Standard*.

#### THE PETROLEUM STATISTICS.

If figures can be believed, it would seem that the consumption of Pennsylvania oil in excess of production will soon bring us face to face with an oil famine, so far as the Pennsylvania product is concerned. It is not a question of the contraction of national transit certificates in existence, as that might arise from an artificial condition

of affairs, created by the issuers and manipulators of them; but the actual consumption at home and the amount exported largely exceeds the production. What the possibilities are for increasing the production is hard to say with certainty, but judging from the small results obtained by the energetic prospecting operations which have been carried on through a great portion of the past year, the probabilities in favour of great or steady increase are small. If this is the true situation, and everything points to it being so, we are fast approaching the time when the accumulated surplus of past years will be exhausted, and at the present rates of consumption and production the latter would be from 20,000 to 30,000 barrels a day behind the former. The energy with which prospecting for new territory is being carried on can be judged of from the enhanced prices paid for even possible oil lands, and the fact that in the past year there were 5,700 wells completed against 1,700 in 1888, and 1,800 in 1887. Prospecting was more active than in the three preceding years, 1884-86, but in the first of these, in which there were the greatest number of wells completed of recent years, the figure only reached 3,400.

The daily output for the year 1889 gave an average considerably in excess of that for 1888, viz., 60,256 barrels, but at the same time it was slightly inferior to that of 1887, which amounted to 61,875 barrels, and greatly below that of 1886, while all the time the consumption has been largely and steadily increasing. The reduction in net stocks by all pipe lines has gone on at about the rate of 650,000 barrels a month, as they amounted on December 31st, 1888, to 18,604,474 barrels, and on the corresponding date in the past year to about 10,800,000. It is unnecessary, however, to contemplate the time when, with stocks exhausted, we shall suddenly find ourselves with a demand that cannot be satisfied, as before that happens the price will surely adjust itself, and the demand will be curtailed in consequence of the article becoming, in certain cases, a luxury instead of a necessity.

The year has opened with a smaller daily production than what we have already recorded as the average of the past year, and the figures point to a large reduction of stocks during the current month, being 54,588 barrels a day, against deliveries, 79,597. Whether this state of affairs will continue can only be more or less a matter of guesswork, and dependent on the foreign markets, but it is interesting to note the decline of shipments of American petroleum to Great Britain during the four years ending 1888, and the increase of Russian petroleum imported into that country. In 1885 there were 1,367,720 barrels of American oil imported against 70,149 barrels Russian; in 1886, 1,363,801 against 46,814; in 1887, 1,444,350 against 188,461; and in 1888, 1,286,148 against 549,126.—*Eng. and Min. Journal, New York*.

#### MINERAL STATISTICS OF CANADA.

The official report of the mining and mineral statistics of Canada, which has just been issued by the Geological and Natural History Survey, gives a list of about twenty-six minerals which are obtained in Canada in quantities of commercial importance. The mineral of most value is, of course, coal, of which in 1888 over 2,500,000 tons were mined, the value at the pit's mouth being over 5,250,000 *dols.* Nova Scotia yields the greatest quantity, nearly 2,000,000 tons, valued at 3,000,000 *dols.*; and British Columbia is second with 500,000 tons, valued at nearly 2,000,000 *dols.*; the North-West territories, whose mines had just been opened, having yielded over 100,000 tons; and New Brunswick about 6,000 tons. Canada exported about 2,000,000 *dols.* worth of coal, and imported about 9,000,000 *dols.* worth, about 5,500,000 *dols.* of which was, however, anthracite, not found in Canada.

Canada's production of iron ore was small—only 79,000 tons, valued at about 150,000 *dols.*, having been mined during 1888. About 22,000 tons of pig iron, of the value of about 313,000 *dols.*, were manufactured in Canada in 1888, a decrease, in spite of the increased duties on pig. Sir Charles Tupper levied duties on pig iron in order to encourage smelting and stimulate mining enterprise.

The following table shows the growth of Canada's product in pig iron:—

*Pig Iron made.*

Year.	Tons.
1876 (no duty; no bounty) .....	4,000
1877 " " .....	13,500
1878 " " .....	16,600
1879 (import duty, 2 dols. per ton) .....	16,500
1880 " " .....	23,600
1881 (duty, 2 dols. per ton; bounty, 1'50 dols. per ton) .....	18,500
1882 " " .....	21,500
1883 " " .....	32,000
1884 " " .....	29,389
1887 (duty, 4 dols. per ton; bounty, 1'50 dols. per ton) .....	24,829
1888 (duty, 4 dols. per ton) .....	21,700

The increase was greater during the period in which there was no duty than during any other period. Canada imported over 68,000 tons of pig iron, handling over 500,000 tons of scrap iron and steel, and about 12,000,000 dols. worth of iron in one form or another, upon which duties amounting to nearly 3,000,000 dols. were paid. There is, therefore, plenty of scope for the development of Canada's iron resources. Of Canada's whole production of iron ore, Nova Scotia is credited with more than half, or over 42,000 tons, Quebec with 10,000, Ontario with 16,000, and British Columbia with 8,000.

The production of gold for the year amounted to over 61,000 oz., valued at over 1,098,000 dols. The rapid development of silver mining in the Lake Superior region is shown by the statistics of Ontario production, which has increased from 16,505 dols. in 1886 to 184,763 dols. in 1887, and to 208,064 dols. in 1888, and the total value of the Dominion's silver production for 1888 amounted to 395,377 dols. Quebec was the only province that mined copper in 1888, the value of which was placed at 667,543 dols., an increase over the production of the two preceding years. Canada is not rich in lead, the only production being that of British Columbia, worth 27,472 dols. The Kootenay and Field mines were the most productive. Platinum to the value of 6,000 dols. was produced in British Columbia, and manganese was produced by Nova Scotia and New Brunswick to the extent of 1,801 tons, of the value of 47,994 dols. The mica product is valued at 30,207 dols. A variety of other metals and mineral substances are alluded to, found in small quantities, but growing in importance. On the west shore of Lake Memphre Magog a rich galena vein has been discovered. An assay shows it contains 70 per cent. of lead and 15 per cent. of silver. The property, which contains over 200 acres, is controlled by McDonald Brothers, Sherbrooke.

**BOARD OF TRADE RETURNS.**

**SUMMARY OF IMPORTS.**

	Month ended 31st January	
	1889.	1890.
	£	£
Metals.....	2,157,316	2,085,663
Chemicals and dyestuffs.....	912,914	810,293
Oils.....	499,769	601,519
Raw materials for non-textile industries.....	2,769,978	2,651,310
Total value of all imports ....	38,958,318	38,143,850

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

## I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

## APPLICATIONS.

606. J. Brock and T. Minton. Filter presses. January 13.  
668. J. S. Rigby and J. R. Wyld. Apparatus for separating from each other the solid and liquid constituents of mud and other semi-fluid mixtures, or for washing said solid constituents. January 14.

828. A. Smith. Filters for the purification of water and other liquids. January 16.

1122. T. E. Wilson. The concentration, evaporation, and distillation of liquids. January 22.

1177. W. Sinclair. A composition suitable for lining casks and like vessels, and for making screw stoppers for bottles. January 22.

1234. R. Mannesmann. Regenerative gas furnaces. January 23.

1235. R. Mannesmann. Compressing air or other gaseous fluid, and apparatus therefor. January 23.

1236. R. Mannesmann. Compressing air or other gaseous fluid, and apparatus therefor. January 23.

1239. D. Bethmont. Apparatus for the instantaneous production of vapour from water or other liquids. January 23.

1242. R. A. Kemp. Apparatus for containing material for absorbing moisture or humidity. January 23.

1307. A. Capillary. Apparatus for filtering liquids. January 24.

1383. R. Johnson. Rotary apparatus for blowing, exhausting, or pumping air, water, and other gases or liquids. January 27.

1476. A. J. Boulton.—From G. Schweickhart, United States. Improvements in tyères. January 28.

1515. H. E. Newton.—From W. J. Maedonagh, R. Rock, W. Wood, C. S. Wilkinson, J. Plummer, and R. B. Wilkinson, New S. Wales. Appliance for injecting liquid and gaseous fuel into furnaces. January 28.

1823. P. S. Conron. Improvements in thermometers for converters, mash tuns, and other vessels used in brewing and other industrial operations. February 3.

1877. A. Riedler. Apparatus for compressing air or gases. Complete Specification. February 4.

1910. J. F. H. Gronwald. Improved sterilising apparatus. Complete Specification. February 5.

1948. H. W. Deacon and V. C. Driffield. Apparatus for separating liquids from solids. February 5.

2055. B. J. B. Mills.—From A. Seigle, Gonjon, France. Apparatus for heating liquid and gaseous bodies. February 7.

2070. C. A. Sahlström and A. F. Hill. Furnaces for burning liquid fuel. February 8.

2139. O. Bellot. Means for regulating the generation of heat in ovens, furnaces, and the like. Complete Specification. February 10.

2207. W. Scollay. Apparatus with means for regulating the admission of air and of gas to Bunsen burners. February 11.

2218. R. Marshall and E. FitzGerald. Surface condensers. February 11.

2343. T. Wrigley. Mechanical stokers. February 13.

2427. A. Fryer. Treatment of solutions or liquids for the purpose of concentration or evaporation, and apparatus therefor. February 14.

2502. W. R. Renshaw. Apparatus for heating, cooling, and condensing fluids. February 15.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1889.

3065. W. S. Squire. Machinery for separation of solid matters from liquids, and for washing out and exhausting the said matters. February 5.

3753. O. M. Row. Apparatus for condensing steam and vapours, and for heating or cooling fluids. February 12.

4354. E. B. Parnell. Calcining furnaces. January 22.

5326. T. F. Shillington and J. A. Hanna. Appliances for heating and circulating liquids by steam. February 5.

5373. P. W. Turner. Wooden vessels for corrosive substances. February 5.

6242. R. Haig. Mechanical retorts for treatment of animal, vegetable, and mineral matters. February 19.

8596. J. G. Chapman. See Class XVI.

10,361. H. H. Lake.—From La Société Anonyme des Parfums Naturels de Caunes. Process and apparatus for the lixiviation of various materials. January 29.

13,598. H. McPhail, E. Simpson, and C. H. Simpson. Method and apparatus for generating steam and evaporating various liquids. February 5.

16,478. A. de Kunwald. Distillatory apparatus. February 19.

19,002. J. E. Searles, jun. Method and apparatus for extracting the liquid or soluble constituents from disintegrated vegetable materials. February 5.

1890.

206. J. F. H. Gronwald and E. H. C. Oehlmann. Sterilising apparatus. February 12.

266. A. Brock and H. A. Romero. An improved air pump. February 12.

## H.—FUEL, GAS, AND LIGHT.

### APPLICATIONS.

788. W. W. Horn.—From C. W. Jarrell, United States. An improved apparatus for washing gas. January 15.

794. H. S. Maxim and G. S. Sedgwick. Improvements relating to the carburetting or enrichment of coal and other gas, and to apparatus therefor. January 15.

910. E. Freund. Improvements in the process of and apparatus for distilling, roasting, or carbonising coal for the manufacture of gas, applicable also to the like treatment of other materials. January 17.

1001. W. H. Nevill. Improvements in the manufacture of artificial fuel, and the treatment of coal, coke, and other similar products with a view to their better combustion. January 20.

1022. T. Walrond-Smith. Improvements in the manufacture of water gases. January 20.

1237. R. Mannesmann. Improvements in the manufacture of illuminating gas, and apparatus for that purpose. January 23.

1238. R. Mannesmann. Improvements in the production of water and illuminating gas, and apparatus for that purpose. January 23.

1283. O. Imray.—From R. Mannesmann and M. Mannesmann, Germany. Improvements in the production of coke, and apparatus for that purpose. January 24.

1285. O. Imray.—From R. Mannesmann and M. Mannesmann. Improvements in gas-producers. January 24.

1349. W. L. Wise.—From E. Solvay and L. Semet, Belgium. Improved method or process for the gasification of fuels, and apparatus therefor. January 25.

1556. W. C. Owston. Coal-saving composition. January 29.

1698. C. Heyer. Improvements in carburetting gases, and in the purification of hydrocarbons for that purpose. Complete Specification. January 31.

1801. P. Scharf. Improvements in heating by means of gas. February 3.

2283. W. Hughes and E. Grippiech. Improvements in or appertaining to apparatus for the manufacture of oil gas. February 12.

2341. F. Scudder and H. G. Colman. Improvements in the manufacture or treatment of gases containing carbonic oxide, such as water-gas and producer-gas, to render them odorons. February 13.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

2093. J. F. M. Pollock. Machinery for manufacturing blocks of compressed coal dust and pitch or other agglomerate; also clay, cement, &c. February 12.

2561. J. Pring. Plant for the manufacture of patent fuel. February 19.

3498. W. R. Hutton. Making briquettes for fuel. January 22.

4288. A. Beeson. Manufacture of fuel. January 29.

4644. F. Siemens. Regenerative gas furnaces and producers. January 22.

4726. R. A. Gilson. Utilising waste heat of gas flame for warming purposes generally, and for increasing luminosity of the flame. January 29.

4869. D. Irving and A. Cochey. Apparatus for extracting ammonia, sulphur, and other impurities from coal gas. January 22.

4880. J. Broad and G. C. Fowler. Improved nightlights, and method of manufacturing same. January 29.

4955. Brin's Oxygen Co. and K. S. Murray. Means for producing oxygen and the like. February 5.

5145. J. H. R. Dinsmore. Manufacture of gas for illuminating and heating, and apparatus therefor. February 5.

5635. G. Bamberg. Automatically maintaining the internal temperature of retorts at full red heat, and preventing the use of temperature beyond full red heat. January 29.

5697. B. E. Kelly, J. H. Spencer, and H. Spencer. Fuel blocks. February 5.

5974. D. S. Hawks.—From E. L. Brady. Anti-corrosive lubricant and lubricating vapour for carbon disulphide and other vapour motors. February 12.

6131. S. Fox and E. Blass. Manufacture of water-gas, and apparatus therefor. February 12.

6325. R. B. Main, A. P. Main, and H. Darwin. Refractory lumps for incandescent gas fires. February 19.

16,489. F. Morris and L. van Vestrant. Apparatus for charging inclined gas retorts. January 22.

20,980. H. E. Newton.—From The Fuel, Gas, and Light Improvement Company, Incorporated. Process and apparatus for the manufacture of gas. February 5.

20,981. H. E. Newton.—From The Fuel, Gas, and Light Improvement Company, Incorporated. Apparatus for the manufacture of gas. February 5.

\* See previous page.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

#### APPLICATIONS.

1107. M. Lange. A method of separating the isomers contained in crude nitrotoluol. January 27.

2242. F. Ilawaty. Improvements in the process of preparing benzol and its homologues naphthalene and anthracene from petroleum, petroleum scales, tar, tar oils, paraffin, vaselin, ozokerit, and the like, and from natural illuminating gas. February 11.

#### COMPLETE SPECIFICATION ACCEPTED.

1889.

4597. W. Young and G. T. Beilby. Distillation of mineral oils, and apparatus therefor. February 5.

### IV.—COLOURING MATTERS AND DYES.

#### APPLICATIONS.

724. J. J. Hummel. See Class XIII.

735. A. Bang.—From Messrs. Dahl and Co., Prussia. The production of dioxynaphthalene-mono-sulpho acid and diazo-dyestuffs from the same. January 15.

1579. J. Imray. — From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, A. F. Poirrier, and D. A. Rosenstiehl, France. Manufacture of azo-amines by the reduction of azo-colouring matters derived from nitramines. January 29.

1688. T. R. Shillito.—From J. R. Geigy and Co., Switzerland. Producing brown dyes or colouring matters. January 31.

1699. O. Imray.—From The Farlowwerke vorm. Meister, Lucius, und Brüning, Germany. Improved manufacture of colouring matter of the induline series, soluble in water. January 31.

1771. T. R. Shillito.—From J. R. Geigy and Co., Switzerland. Production of yellow dye or colouring matter. February 1.

1808. O. Imray.—From the Society of Chemical Industry in Basle, Switzerland. Production of yellow basic colouring matter. February 3.

1811. R. Holliday. Improvements in the manufacture of colouring matters. February 3.

1812. R. Holliday. Improvements in the manufacture of colouring matters, and in dyeing or printing wool and other fibres therewith. February 3.

1828. B. Willecox.—From The Farbenfabriken vorm. F. Bayer and Co., Germany. Improvements in the manufacture of azo-colouring matters for dyeing and printing. February 3.

1874. J. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, and Dr. Chapuis, France. Production of soluble blue colouring matters of the induline class. February 4.

1962. A. Bang.—From Messrs. Dahl and Co., Prussia. Improvements in the production of yellow dyestuffs. February 6.

2011. W. S. Conrad and H. T. Lilley. An improved copying ink. Complete Specification. February 7.

2499. H. H. Lake.—From K. Ochler, Germany. Improvement in the manufacture of soluble blue cotton dyestuff or colouring matter. February 15.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

1046. B. Willecox.—From The Farbenfabriken vorm. F. Bayer and Co. Production of unsymmetrical acid green. January 22.

2360. E. Brasier and J. H. Knowles. A new extract, and its utilisation as a dye, ink, stain, tanning liquor, and the like. January 29.

3048. I. Levinstein. Manufacture of red colouring matters for dyeing and printing. January 22.

3441. C. Dreyfus. Production of colouring matter from phenol-phtalein. January 22.

5549. O. Imray.—From The Farbenfabriken vorm. Meister Lucius und Brüning. Manufacture of green and bluish-green colouring matters. January 29.

5785. J. Y. Johnson.—From F. von Heyden. Production of oxymetho-oxybenzoic acids. February 12.

### V.—TEXTILES, COTTON, WOOL, SILK, Etc.

#### APPLICATIONS.

682. O. Imray.—From the Celluloid Manufacturing Co., United States. Waterproof collar, cuff, and bosom, composed partly of vegetable parchment. Complete Specification. January 14.

683. O. Imray.—From the Celluloid Manufacturing Co., United States. Collar, cuff, and bosom, with waterproof body, and coverings having a coating of pyroxyline varnish. Complete Specification. January 14.

725. G. Broadbridge.—Partly communicated by M. J. de Sant Anna, Lagos. Improved bast or piassava substitute, and manufacture of same. January 15.

1461. J. Smith, I. Smith, and J. Smith. Improvements in the method of and apparatus for treating or scouring and washing wool and other fibrous substances. January 28.

1462. J. B. Whiteley and E. Whiteley. A new or improved method and means for drying or extracting moisture from wool, cotton, and other like fibres or fibrous materials. January 28.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

4991. J. Yates and G. Kay. Open soapers for soaping and dunging fabrics. January 29.

20,936. L. Pinagel. Process and apparatus for freeing wool from grease. February 12.

### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

#### APPLICATIONS.

703. R. Haddan.—From B. Leplat, France. Apparatus for use in treating and dyeing cotton slivers, rovings, or caps, and other textile materials. Complete Specification. January 14.

903. E. Charles. Improvements in vats employed in dyeing. January 17.

1062. S. Knowles and J. Knowles. Improvements in the production of azo-colours upon cotton or other vegetable fibre in the piece, and in apparatus therefor. January 21.

1157. G. Young and F. Pearn. Improvements in mechanism or apparatus for dyeing and bleaching cotton, wool, silk and other fibrous materials in the raw and manufactured, or partly manufactured state. January 22.

1607. J. Smith, I. Smith, and J. Smith. Improvements in the method of and apparatus for mordanting and dyeing wool, cotton, and other fibre, and also for extracting or separating animal from vegetable fibre. January 30.

1702. G. H. Craven. Improvements in dyeing machines. Complete Specification. Filed January 31. Date applied for July 22, 1889, being date of application in United States.

1812. R. Holliday. See Class IV.

1813. R. Holliday. Improvements in dyeing textile fibres. February 3.

2195. I. Braithwaite. Improvements in or appertaining to dyeing with indigo. February 11.

2338. J. Boardman and J. Higginson. An improved means of treating or dyeing hats, caps and other head coverings, whereby they change colour with alteration in atmospheric conditions. February 13.

2381. J. Königswerther. See Class XIV.

2411. T. Ingham. Improvements in dyeing cotton. February 14.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

4602. H. A. Seegall. See Class XIII.

4991. J. Yates and G. Kay. See Class V.

5995. D. G. FitzGerald. Bleaching by the agency of chlorine and certain of its compounds. February 19.

1890.

703. R. Haddan.—From B. Leplat, France. Apparatus for use in treating and dyeing cotton slivers, rovings, or caps, and other textile materials. February 19.

### VII.—ACIDS, ALKALIS, AND SALTS.

#### APPLICATIONS.

670. A. Domeier.—From E. K. Mitting, United States. Improvements in purifying salt. Complete Specification. January 14.

779. H. H. Leigh.—From H. P. Lorenzen, H. Stahr, and R. Heinz, Germany. Obtaining alumina and phosphoric acid from phosphates of alumina. January 15.

858. C. Roth. Improvements in the manufacture or separation of ammonium nitrate, and sulphate, or chloride of sodium, and of potassium. January 16.

933. W. Feld. Improvements in the manufacture of pure caustic soda from sodium sulphate, sulphur being recovered as sulphuretted hydrogen. January 18.

984. H. Grimsnaw. An improved compound for the generation of carbon dioxide, and suitable for use in gazogenes, fire extinguishers, and similar apparatus. January 20.

1015. F. Ellershausen. Improvements in the manufacture of soda and potash. January 20.

1016. F. Ellershausen. Improvements in the manufacture of soda and potash. January 20.

1117. J. Massignon and E. Watel. Improvements in the manufacture of chromates, bichromates, and other chromium compounds. January 21.

1259. G. Dames. A machine or appliance for use in manufacturing for making solution or wash of dried Fuller's earth, alkalis, or other substances, and at the same time screening and separating therefrom all hard and insoluble substances. January 24.

1300. H. H. Leigh.—From T. de Brochowski, France. Improvements in the manufacture of anhydrous barium oxides. Complete Specification. January 24.

1524. G. Wischin. Improvements in the method of vaporising solutions containing nitrates of manganese, and in the means used for decomposing the said nitrates. January 28.

1584. F. Ellershausen. Improvements in the manufacture of soda and potash. January 29.

1653. G. Kennedy. Improvements in and connected with saturators for sulphate of ammonia plant. Complete Specification. January 30.

1848. A. R. Davis. Improvements in apparatus for the distillation of liquors containing ammonia. February 4.

1914. F. M. Spence and D. D. Spence. Improvements in the manufacture of alum. February 5.

1964. W. O. Kibble. Improved apparatus for generation of sulphuretted hydrogen and other gases. February 6.

2296. J. C. Richardson and T. J. Holland. See Class XI.

2432. A. M. Chance and H. W. Crowther. Improvements in the manufacture of nitrate of ammonia. February 14.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

4095. F. Mühlenbrüch. Producing monocarbonate of calcium. January 22.

4417. W. L. Wise.—From E. Solvay and Co. Manufacture of anhydrous chloride of magnesium, and of chlorine therefrom. January 29.

4701. S. Daw. Treating waste or spent sulphuric acid pickle from the manufacture of tin, terne, and black plate. February 12.

5225. R. Dormer. Obtaining chlorine. February 12.

5340. G. A. H. Gabet. Manufacture of ammoniacal calcic phosphate. January 29.

5341. G. A. H. Gabet. Manufacture of potassic and sodic alkalis. February 12.

5779. J. W. Kynaston and J. Sutherland. Treating recovered ash from paper mills. February 12.

6668. M. Netto. Manufacture of artificial cryolite. February 19.

17,272. P. de Wilde and A. Reyehler. Processes for the production of chlorine and for obtaining concentrated gaseous hydrochloric acid for that purpose. January 29.

20,135. J. E. J. Johnson. Manufacture of acetic acid and soluble acetates. January 22.

20,722. J. C. Fell.—From The American Ammonia Manufacturing Company. Method and apparatus for obtaining ammonia from atmospheric nitrogen and the hydrogen of decomposed steam. February 12.

20,908. M. B. Mason, S. D. Warren, and F. Warren. Method and apparatus for recovering chemicals from solutions or when mixed with substances which are volatilisable or destructible by heat, especially adapted for recovering soda from waste liquors of pulp digesters. February 12.

### VIII.—GLASS, POTTERY, AND EARTHENWARE.

#### APPLICATIONS.

612. W. C. Bennett. Improvements in the manufacture of glass bottles, and apparatus therefor. January 13.

738. C. F. Bailey. Improvements in the method or means for supporting pottery-ware whilst being fired. January 15.

830. H. L. Phillips. Improvements in or connected with the manufacture of glass bottles, jars, and similar vessels, and in apparatus employed therefor. January 16.

927. W. W. Pilkington. Improvements in plate and rolled plate glass annealing kilns and machinery. January 18.

1011. H. Worthington. Improvements in garden tiles. January 20.

1013. J. P. Guy. Improvements in machines for pressing and making hollow earthenware articles. January 20.

1215. H. Walker. Improvements in annealing and other heating furnaces. January 23.

1588. J. Bates and R. Stanley. Improvements in the manufacture of burnt-clay or earthenware goods. January 29.

1666. T. Bellamy. An improvement in glass melting pots. January 31.

1803. L. Appert. New or improved method of moulding glass, and apparatus therefor. Filed, February 3. Date applied for, August 29, 1889, being date of application in France.

1815. A. Bevington. Improvements in decorating china, earthenware, and the like. February 3.

1820. H. Gurney. An improved method of burning bricks and tiles, and an improved kiln therefor. Complete Specification. February 3.

2487. J. McMillan. Apparatus for making bottles or other articles having a narrow orifice in glass, crystal, or similar molten metals, with a certain modification of same for making similar articles in clay, stone, flint, or china ware. February 15.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

5048. D. Rylands. Moulds for forming bottles by the pressing and blowing process. January 29.

5205. H. L. Doulton and S. H. Leech. Manufacture of blocks of terra-cotta, &c., and apparatus therefor. February 12.

5691. J. A. Edwards. Method and apparatus for supporting earthenware and porcelain whilst being fired. February 5.

5992. J. Rhodes. Manufacture of china and earthenware saucers. February 12.

7387. G. Falin. Improvement of fireclay goods by adding sugar to the compound known as silica and alumina. February 5.

13,051. J. Peirce and T. F. Luther. Enamelled metallic tessellated plates for hearths and floors. February 5.

19,744. G. A. Marsden. Manufacture of tiles, bricks, &c. having ornamented surfaces. January 22.

#### IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

##### APPLICATIONS.

617. F. T. P. Wells. An improved treatment of wood for the purpose of rendering it practically indestructible. January 13.

1097. H. H. Lake.—From J. F. Gesner, United States. Manufacture of an artificial solid material, and apparatus therefor. Complete Specification. January 21.

1176. W. Sinclair. A compound for cementing iron rails to stone kerbing, joints of stone, drain pipes, ships' seams, and the like. January 22.

1248. W. W. Horn.—From J. S. Goodwin, United States. An improved building block. January 23.

1351. J. E. H. Gordon. Improvements in pavements. January 25.

1356. A. J. Boulton.—From W. Deissner, Germany. Improvements in the manufacture of rough, glazed, and coloured facing stones. Complete Specification. January 25.

1525. I. Button, E. Peters, and J. W. Goodsell. Improvements in kilns or ovens for burning bricks, earthenware, limestone, cement, and other substances. Complete Specification. January 28.

1654. M. B. Parrington. Improvements in the manufacture of lime, and in apparatus therefor. January 30.

1934. C. Eifield. An improved silicious paving and building stone. February 5.

2371. C. H. Edwards. Improvements in or appertaining to the manufacture of certain kinds of bricks and fireclay substitutes. February 13.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

2093. J. F. M. Pollock. See Class II., February 12.

4946. R. R. Clunis. Improvements in bricks. January 22.

5157. J. W. H. James. Manufacture of cement. February 5.

18,487. H. H. Lake.—From G. M. Fiske. Improvements relating to the construction of brickwork. February 12.

18,493. H. H. Lake.—From G. M. Fiske. Improvements in bricks. February 12.

18,911. P. de Kristoffovitch. Manufacture of artificial granite. January 29.

19,744. G. A. Marsden. See Class VIII.

#### X.—METALLURGY, MINING, ETC.

##### APPLICATIONS.

840. R. Manuesmann. Improved means of mixing molten metal in furnaces or converters. January 16.

859. W. White. Improvements in or connected with the manufacture or production of aluminium. January 16.

877. D. Elliott. Improvements in furnaces for heating iron or steel. January 17.

1053. H. Grimshaw. Improvements in and connected with the recovery of zinc from galvanised iron and steel. January 21.

1215. H. Walker. See Class VIII.

1227. E. C. Miller.—From The Magnolia Anti-Friction Metal Co., United States. Method of preparing or treating metals for the manufacture of compositions or alloys for anti-friction purposes. January 23.

1355. A. E. Haswell and A. G. Haswell. Improvements in the coating of iron, steel, nickel, zinc, or tin, for the prevention of corrosion. January 25.

1369. G. C. Fricker. Improvements in cleaning and annealing iron, and apparatus therefor. January 25.

1427. M. Netto. Improvements in the manufacture of metallic compounds or alloys. January 27.

1443. J. T. King.—From C. Adams, United States. Improvements in the reduction of metallic ores, and in apparatus therefor. January 28.

1522. T. H. Johns. Improved construction or arrangement of apparatus for coating hoop iron with tin or terne metal. January 28.

1624. A. H. Holdich. An improved form of stopper or valve for controlling the flow of steel from the ladle or reservoir used in steel works. January 30.

1625. F. K. S. Lowndes and J. C. Kaller. A machine for the extraction of gold, silver, and other metals from quartz and ailings, blanketings, &c., by a continuous process of chlorination and amalgamation. January 30.

1634. G. D. Burton. Improvements in the manufacture of forgings. Complete Specification. January 30.

1641. F. W. Dähne. Improvements in calcining and refining copper ore, copper regulus, and copper precipitate, and in the construction of furnaces therefor. Complete Specification. January 30.

1647. — Hopkinson. Hardening metallic alloys. January 30.

1682. R. Heathfield. Improvements in apparatus or machinery for coating metal sheets with metals or alloys. Complete Specification. January 31.

1691. D. Ormerod. Improvements in metal alloy for use in pipe-jointing, also applicable for moulding and casting purposes. January 31.

1733. J. F. Spencer. Improvements in machinery or apparatus for charging pig iron and scrap metal into open-hearth furnaces. February 1.

1754. G. Höper. Improved method of and apparatus for the manufacture of dense-metal castings, and of sheet metal and wire therefrom. February 1.

1794. C. Pfeiffer. An improved amalgamator for extraction of gold and silver from the ore by the action of mercury. February 3.

1806. M. R. Conley and J. H. Lancaster. An improved process for making steel, and apparatus therefor. February 3.

1842. E. L. Mayer and J. G. Lorrain. Improvements in or connected with the treatment and recovery of float-gold. February 4.

1888. R. C. Totten. Improvements in and relating to castings, such as dies, ingots, and other castings. Complete Specification. February 4.

1913. W. P. Thompson.—From E. Carez, Belgium. Improvements in or relating to the treatment or utilisation of scrap tin orterne plates, or the like. February 5.

1987. S. Wohle. A process for electro-plating metals with aluminium, or its alloy with nickel. February 6.

2002. G. Shenton.—From M. J. Berg, France. Improvements in the manufacture or production of aluminium. February 6.

2057. A. J. Campion. Improvements in processes for smelting and treating tin ores, slags, slimes, and furnace debris containing tin and other products. February 7.

2226. N. Lebedeff. Improvements in extracting iron, copper, nickel, or other metals or alloys from combinations thereof with other substances. February 11.

2248. F. W. Harbord. Improvements in the utilisation of tin-plate scrap. February 12.

2312. J. Teague. An improved process of extracting tin and other metals associated therewith from tin slags and other tin products or refuse. February 12.

2390. J. Buchanan, jun. Improvements in the method of precipitating gold or silver in the process of its extraction. February 14.

2477. T. Teague. An improved process for the extraction of tin from slags or tin debris. February 15.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1888.

18,211. G. E. Vaughan.—From L. Weiller. Manufacture of metallic alloys or compounds. January 22.

1889.

2350. T. Bell. Method of lining barrels, &c., to resist acids, for use in extracting metals by chlorination, &c. February 12.

2377. A. C. A. Holzapfel. Machine for flanging and shaping steel, iron, and other metal plates. February 5.

2937. E. B. Parnell. Treatment of ores for recovery of metals therefrom, and apparatus therefor. January 22.

4003. E. Lones, R. Davies, J. Davies, and B. A. Webb. Coating metal plates with tin and other metals, and apparatus therefor. January 22.

4169. J. L. E. Daniel. Manufacture of aluminium, and apparatus therefor. February 19.

4537. A. Hodgkinson, jun. Treatment of the calcined products of ironstone mines and shale, and manufacture of same into blocks for the extraction of iron therefrom. February 5.

4719. T. R. Jordan. Apparatus for extraction of gold and silver from their ores. January 29.

4882. P. C. Gilchrist. Manufacture of copper. February 5.

5037. D. Owen. Apparatus for the purification of molten tin or its alloys. January 29.

5078. A. E. Barthel. Production of fixed or detachable deposits of homogeneous iron in any form from iron ores, or iron or steel. February 5.

5195. J. Lones, C. Vernon, E. Holden, and R. Bennett. Manufacture of buffer iron or steel. January 22.

5914. E. Green. Production of aluminium. January 29.

6026. F. W. Rose.—From T. K. Rose and D. Dennes. Method and apparatus for treating ores. February 19.

7311. R. Heathfield. Apparatus used in coating metal sheets with metal or alloys. January 22.

13,659. W. L. Wise.—From M. Kramer. Hardening steel tubes internally. February 5.

13,718. A. M. Clark.—From La Société en participation Bourbonze et Cie. The production of a new metal or alloy. February 12.

16,649. G. G. Mullins. Treating copper and its alloys. January 29.

19,890. H. Aiken. Casting ingots, blooms, billets, slabs, or the like, and apparatus therefor. February 5.

19,944. J. A. H. T. Ranft. Process and apparatus for the continuous extraction of gold and silver by the agency of chlorine. February 12.

20,180. R. F. Neuninger. Combined smelting and reverberatory furnace and apparatus for catching the dust and condensing the fumes from the furnace. January 29.

#### XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

##### APPLICATIONS.

761. O. Dahl. Process of generating electricity by gas batteries. Date applied for June 17, 1889, being date of application in United States. Complete Specification.

907. W. A. Thoms. Improvements in the electro-deposition of metallic alloys. January 17.

1094. H. H. Lake.—From T. Ewing, United States. Improvements relating to secondary or storage batteries. Complete Specification. January 21.

1110. C. A. Hitchcock.—From W. Barnley, United States. An improvement in galvanic batteries. Complete Specification. January 21.

1246. D. G. FitzGerald and A. C. Falconer. Improvements in means for the electrolytic generation of chlorine and compounds of chlorine with earthy bases, more especially intended for bleaching purposes. January 23.

1281. V. H. Ernst. Improvements in secondary batteries. Filed January 24. Date applied for, September 28, 1889, being date of application in United States. Complete Specification.

1306. C. Smith.—From W. L. F. Hellesen, Denmark. Improvements in galvanic dry elements. January 24.

1347. T. Coad. An improved fluid for primary batteries. January 25.

1495. H. H. Lake.—From G. A. Johnson, United States. Improvements relating to storage batteries or accumulators. Complete Specification. January 28.

1784. T. A. Garrett. Improvements in and connected with the production of ozone by means of electricity. February 3.

1878. J. B. Williams. Improvements in electric insulating compounds. Complete Specification. February 4.

1897. E. Fabrig. An improved composition applicable for electrical insulating and other purposes, and the process for manufacturing the said composition. January 4.

2091. W. P. Thompson.—From the Gibson Electric Co. of Europe, France. Improvements in secondary batteries and plates or elements therefor. February 8.

2113. G. A. Schoth. Improvements in the manufacture of plates of electrodes as used in secondary batteries or accumulators. February 10.

2273. G. R. Postlethwaite. Improvements in voltaic cells or primary batteries. February 12.

2296. J. C. Richardson and T. J. Holland. Improvements in the electrolytic production of caustic soda, caustic potash, and other products from their salts. February 12.

2297. J. C. Richardson and T. J. Holland. Improvements in apparatus to be used for electrolytic purposes. February 12.

2302. H. Weymerseh and R. McKenzie. Improvements in electric batteries working with two liquids or electrolytes. February 12.

2347. Sir C. S. Forbes, Bart. Improvements in primary batteries. February 13.

2439. F. S. Roberts. Improvements in or connected with electrical accumulators or storage batteries. February 14.

2606. E. C. F. Verschave and A. Baron. Improvements relating to electric batteries. February 15.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

813. W. Diehl. Separation of aluminium and its alloys from its fluorides by electric or by chemical metallurgical process. January 22.

2472. W. L. Wise.—From the Gibson Electric Co. of Europe. Secondary battery plates. February 19.

2544. A. Douglass and F. Smith. Improvements in the form and manufacture of secondary battery frames and plates. January 22.

3533. C. D. Abel.—From Siemens and Halske. Extraction of copper and zinc from their ores, as also the precious metals contained therein, by electrolysis, and apparatus therefor. January 22.

7719. P. Schoop. Electric or galvanic elements or cells. February 19.

11,661. C. Huelser.—From H. Mestern. Thermo-electric and furnace batteries. January 22.

14,677. R. R. Moffatt. The utilisation of electromagnetism for the separation of metals, and apparatus therefor. January 29.

19,892. H. E. Fowler. Apparatus for welding metal by means of electricity. January 22.

20,911. A. E. Woolf. Plates for storage batteries. February 12.

1890.

302. H. H. Lake.—From P. H. Alexander. Secondary batteries and plates therefor. February 12.

303. H. H. Lake.—From P. H. Alexander. Secondary batteries. February 12.

#### XII.—FATS, OILS, AND SOAP MANUFACTURE.

##### APPLICATIONS.

656. J. Templeman. Improvements in the manufacture of soaps and saponaceous compounds. January 14.

983. H. Grimshaw. Improvements in soap and soap powder for use with hard and sea waters. January 20.

1047. E. Ireland. An improvement in soap called "Aurora herbal cosmetic soap." January 21.

1069. A. F. St. George. Decolourising and oxidising or solidifying drying oils for manufacturing purposes. January 21.

1109. H. Noerdlinger. Treatment of press and extraction residues of oil manufacture for obtaining valuable products therefrom. January 21.

1126. C. W. Hazlehurst and S. Pope. Improvements in the treatment or utilisation of salt obtained from spent soap lyes in the recovery of glycerin therefrom. January 22.

1343. T. H. Gray and S. S. Bromhead. Improvements in refining linsced and other oils. January 25.

1650. M. Perls. Improvements in the manufacture of soap. January 30.

1652. B. D. Barnett. Improvements in the process of cleaning and extracting oil and grease from cotton waste and other fibrous materials. January 30.

1659. P. Plisson. Improvements in the manufacture of lubricating grease, and in the apparatus employed therefor. Complete Specification. January 30.

2104. P. Wild. Process and apparatus for melting margarine tallow by means of hot air. February 8.

2264. J. Green and G. Macdonald. An improved lubricant or grease. February 12.

2336. H. Harford. An improved method of making lubricating grease. February 13.

2446. A. des Cressonnières and E. des Cressonnières. Improved process and apparatus for the manufacture of kneaded or agglomerated soaps. February 14.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

4367. W. G. Reid. Treatment of used soapy liquors. January 29.

5622. J. Pearson. Treating cotton-seed oil mangle to obtain soap. February 5.

20,237. W. Rödiger. Manufacture of soap. January 22.

#### XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

##### APPLICATIONS.

724. J. J. Hummel. New or improved red dye or pigment, and process for making and applying the same. January 15.

764. W. H. Barnes. Improvements in compositions to be used as paints. January 15.

812. W. H. Ness and W. C. Folkard. An improved preservative composition or solution for coating surfaces of articles or structures where great adhesiveness is required. January 16.

893. A. N. Ford. An improved composition for insulating and waterproofing purposes. January 17.

985. H. Grimshaw. A new or improved white pigment. January 20.

1178. W. Sinclair. Waterproofing and preserving composition for stone, bricks, plaster, and cement surfaces. January 22.

1489. J. J. E. Mayall. Improvements connected with colouring photographic impressions, and in the mixing and preparing the colours, and in a varnish or enamel for same. January 28.

1684. A. J. Boulton.—From N. A. Bibikof, New Mexico. Improvements in paints. Complete Specification. January 31.

1821. C. B. Phillips and H. R. Lewis. Improvements relating to the application of metallic copper to the hulls of iron or steel and other sea-going ships or vessels and other submerged structures to prevent fouling thereof, and to the manufacture of compositions or pigments to be used for this purpose. February 3.

2308. H. Beck.—From E. Schaal, Germany. Process for the production of resin acid esters applicable as substitutes for the lacquer-resins or gums generally used in the manufacture of lacquers and varnishes. Complete Specification. February 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

4179. S. Kenyon. Preparation of a substance applicable as a substitute for india-rubber, and for waterproofing or dressing fabrics, &c. January 22.

4602. H. A. Seegall. Production of chrome preparations. February 19.

5344. F. Greening. Production of a substitute for ivory, horn, whalebone, india-rubber, &c., useable as a coating or varnish for waterproofing, &c. February 12.

5349. J. Freemont. Manufacture of coloured sealing-wax. January 22.

20,010. J. H. Bath. A hoot-blackening powder. January 29.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

## APPLICATIONS.

981. H. Grimshaw. Improvements in and connected with the recovery of tannin from waste leather. January 20.

1482. W. P. Thompson.—From F. G. Hermann, France. Improvements in apparatus for removing the hair from skins. Complete Specification. January 28.

1576. S. Wohle. Improvements in the treatment of leather to render it impervious, strong, and durable. January 29.

2366. A. Leturque. Improved indicating apparatus for use in connexion with tanning and similar vats. February 13.

2381. J. Koenigwerther. A new process for the dyeing of skins, hairy skins, or fabrics. February 13.

## XV.—AGRICULTURE AND MANURES.

## APPLICATIONS.

575. M. C. Ginster. Improvements in the process of manufacturing a manure or fertiliser from organic matter. January 13.

2238. C. W. Doughty. An improvement in the means and proportions of materials used for the deodorisation, evaporation, and, to a certain extent, decomposition of human excrement and its transformation into a nearly inodorous and valuable fertiliser. Complete Specification. February 11.

2265. J. Pipe and H. D. Andross. An improved compound for treating vines and other plants for the prevention and destruction of phylloxera, mildew, and the like, and the method of producing the same. February 12.

2450. F. Dorr. Improvements in the process of treating cereals. Complete Specification. February 14.

## COMPLETE SPECIFICATION ACCEPTED.

1889.

5703. H. J. Kirkman. Treatment and utilisation, for agricultural and other purposes, of bisulphate of soda or nitre cake. February 12.

## XVI.—SUGARS, STARCHES, GUMS, ETC.

## APPLICATIONS.

1247. A. Fairgrieve. Improvements in the manufacture or production of raw or refined sugar, and apparatus to be used therein. January 23.

1282. C. D. Abel.—From Messrs. Pfeifer and Langen, Germany. Improved treatment of sugar crystals or grains for facilitating the purifying or washing thereof. January 24.

1536. E. Woolley and W. H. Evans. An improved adhesive medium. January 29.

1809. H. T. Brown, G. H. Morris, and E. R. Moritz. Manufacture of amyloins. February 3.

2197. W. P. Thompson.—From K. Korenar and F. Zwicker, Austria. A new or improved adhesive cement and process of manufacturing the same. February 11.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

3526. A. G. Salamon. Preparation of cane and beet sugar. February 12.

20,515. C. Steffen. Process for obtaining the entire quantity of crystallisable sugar contained in sugar mass. February 12.

## XVII.—BREWING, WINES, SPIRITS, ETC.

## APPLICATIONS.

667. W. P. Thompson.—From J. A. H. Hasbrouck, United States. New or improved process and apparatus for ageing liquors. January 14.

678. E. Edwards.—From F. Hofmeister, Germany. Improved method of and apparatus for obtaining accelerated fermentation and producing sparkling drinks. January 14.

792. G. Guignard and A. Hédonin. Improvements in and relating to the manufacture of alcohol, and in apparatus therefor. January 15.

980. H. Grimshaw. Improvements in the process of ageing or artificially maturing whisky and other spirituous liquors. January 20.

1573. A. Rock. Improvements in and relating to malt kilns. January 29.

1823. P. S. Conron. See Class I.

1921. C. Gibbs. A method of and apparatus for condensing steam in brewing coppers. February 5.

1996. J. F. Littleton. Improvements in rousing beer and mixing or blending wort or gyle, and in apparatus employed therein. February 6.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

3574. M. P. Halschek. Improved system of "pneumatic" malting. January 29.

4549. E. A. Barbet. Rectifying and distilling alcohol, and apparatus therefor. January 22.

5647. C. Schmitt. Purification of raw spirit to produce highly rectified spirits of wine, and apparatus therefor. February 5.

8596. J. G. Chapman. Apparatus for evaporating and concentrating saccharine and other solutions. February 12.

19,996. W. Spilker, H. Bendel, M. Hahn, and C. Löwe. Killing minute organisms, such as yeast cells, bacilli, and the like, contained in wines, alcoholic and other similar liquors. January 22.

# XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

## APPLICATIONS.

### A.—Chemistry of Foods.

982. H. Grimshaw. Improvements in the method of producing infusions of tea and similar solutions free from tannin. January 20.

1326. A. Schmidt-Mülheim. Improvements in the method of and apparatus for the production and preservation of sterilised milk. Complete Specification. January 25.

1328. J. T. Appleberg. Improved apparatus for preserving and purifying milk. Complete Specification. January 25.

2060. H. A. Snelling. A new or improved method of treating and preparing hops, and blending the same for infusion together with tea, coffee, cocoa, and other substances for which such prepared hops are applicable. February 7.

2300. D. Browne. A new process for preserving eggs. February 12.

### B.—Sanitary Chemistry.

1170. C. A. Brown. Improvements in furnaces for burning tan and other refuse material. January 22.

1279. A. Moseley. Preparing and compressing quick lime or gypsum so that its use may be more generally adapted for the more rapid decomposition of human bodies. January 24.

1623. W. Warner. Improvements in apparatus employed in treating sewage. January 30.

1816. G. W. Ewens. Improvements in purifying the sewage of cities and towns, and foul waters discharged from breweries, tan yards, glue works, and other description of manufactory. February 3.

2238. C. W. Doughty. See Class XV.

### C.—Disinfectants.

1017. W. Dammann. An improved process for rendering tar oils soluble in water, and the production of disinfectants and other useful products therefrom. January 20.

1289. A. Arnott. See Class XIX.

1589. C. T. Kingzett. Improvements in the manufacture of disinfectants, antiseptics, deodorants, insecticides, and sanitary reagents. January 29.

2047. H. Oppenheim and G. H. Elliott. Candles for disinfecting and diffusing ozone in sick and close rooms. February 7.

## COMPLETE SPECIFICATIONS ACCEPTED.

### A.—Chemistry of Foods.

1889.

4715. J. F. Pensgood. Preparation of tomato vinegar. February 5.

4966. J. Gray and T. Clement, jun. Means of estimating the acidity in milk, cream, whey, and curds in the process of making butter or cheese. February 5.

20,614. W. Douglas and J. Donald. Preserving fish, birds, and other analogous articles of food. February 12.

### B.—Sanitary Chemistry.

1889.

6219. W. Astrop. Process for deodorising, disinfecting, drying, and pulverising the solid portions of sewage. February 19.

16,388. G. W. Bremner. Lumps for destroying sewage gas and noxious vapours. January 22.

1890.

206. J. F. H. Gronwald and E. H. C. Oehlmann. See Class I.

### C.—Disinfectants.

1889.

2537. A. J. Shilten. A new disinfectant and deodoriser. February 5.

6411. F. W. A. Hillé. Manufacture and use of disinfectants. February 12.

# XIX.—PAPER, PASTEBOARD, ETC.

## APPLICATIONS.

795. R. Stone. Improvements in the treatment and utilisation of peat, saw-dust, and other fibrous and vegetable materials and substances. January 15.

1087. T. Goodall. An improved arrangement of roasting apparatus for the incineration of black liquor and spent soda lyes used in the boiling of esparto grass or other fibrous matter. January 21.

1289. A. Arnott. A new disinfecting paper. January 24.

1514. F. C. Alkier. Improvements in extracting substances dissolved in the waste-water of paper manufacture. Complete Specification. January 28.

1651. M. Perls. Improvements in the manufacture of paper. January 30.

2375. H. Colley. Improvements in or relating to the manufacture of paper, and in apparatus therefor. February 13.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

4264. T. Phoenix and G. Kirk. Preparation of tissue transfer paper, and of printed transfers for transferring designs to pottery ware. January 22.

8509. F. Favier, jun. Machinery for refining and finishing half-stuff in paper-making; and hydrostatic balances for changing the contents of the pulp reservoirs. January 29.

# XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

## APPLICATIONS.

1380. R. J. Downes. A solution of iodine for medical purposes. January 27.

1422. A. A. Vale.—From The Chemische Fabriks-Aetien Gesellschaft, Germany. Process of manufacturing eumaron and its homologues. Complete Specification. January 27.

1583. S. Radlauer. Improvements in the preparation of ethyl chloral urethane. January 29.

1988. F. L. Johnstone. Improvements in apparatus for filtering and derisining perfumes, tinctures, essences, cordials, and other liquids. Complete Specification. February 6.

2129. G. S. Dobrashian. Compound syrup of Sarracenia purpurea. February 10.

## XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

### APPLICATIONS.

1489. J. J. E. Mayall. *See* Class XIII.

1956. E. Ireland and C. Ireland. A new or improved method of producing coloured photographs. February 5.

## XXII.—EXPLOSIVES, MATCHES, ETC.

### APPLICATIONS.

1884. P. Jensen.—From H. G. Underwood, United States. Improvements in solidified pyrotechnic powders, and in the method of converting the same into solid form for convenience in transportation, storage, and combustion. Complete Specification. February 4.

1995. W. P. Thompson.—From J. Hess, Belgium. Improvements in or relating to lucifer matches. February 6.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

4477. H. S. Maxim. Manufacture of explosive compounds. January 22.

4479. A. V. Newton.—From A. Nobel. Preparation of explosive compounds. February 19.

5031. P. de Montravel.—Partly by O. Mauvant. Manufacture of explosives. January 22.

5503. E. Liebert. Manufacture of explosive compounds. February 5.

6399. C. O. Lundholm and J. Sayers. Manufacture of explosives. February 19.

## XXIII.—ANALYTICAL CHEMISTRY.

### APPLICATIONS.

1082. G. C. Topp. Improvements to prevent hydrometers, saccharometers, and lactometers rotating, and to strengthen the same. January 21.

1209. J. H. R. Paterson. Raising and adjusting the position of the flame of a Bunsen's and Argand-Bunsen's, or other gas burner used for heating chemical or physical apparatus. January 23.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

6083. L. Mathieu and J. Morfaux. Process and apparatus for testing the presence of colouring matter in wines. February 12.

20,859. I. K. Lindström. Method and apparatus for determining the quantity of fat in milk. February 19.

# THE JOURNAL

OF THE

# Society of Chemical Industry:

## A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 3.—VOL. IX.]

MARCH 31, 1890.

[Non-Members 30/- per annum; Members  
21/- per Set of extra or back numbers;  
Single Copies (Members only) 2/6.

## The Society of Chemical Industry.

### Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S. ....	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S. ....	1882—1883.
Walter Weldon, F.R.S. ....	1883—1884.

## NOTICES.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

Notice is hereby given that the Annual General Meeting will be held in Nottingham in the month of July next. Full particulars will appear in a subsequent issue.

#### LIST OF MEMBERS ELECTED, 21st MARCH, 1890.

Ashplant, Wm. G., Park Villa, Great Torrington, North Devon, manure manufacturer.

Bailey, C. Stuart, Waltham Abbey, Essex, engineer.

Baird, H. Harper, 14, Cross Street, Hatton Garden, E.C., laboratory furnisher.

Barracough, Wm. H., Pembroke House, Atherton Road, Forest Gate, E., analytical chemist.

Bennett, Wm., Belmont House, Grimsby, chemical manure manufacturer.

Bloxam, W. Popplewell, Royal Naval College, Greenwich, S.E., chemist.

Burn-Murdoch, J. V., c/o Van Ryn Gold Mining Co., Boksburg, S.A.R., assayer.

Barringtons, Silas M., Snow Hill Buildings, E.C., manufacturing chemist.

Cassal, C. E., Brenne House, Wandsworth Common, S.W., public analyst.

Cooksey, Dr. Thos., 21, Brownwood Park, London, N., consulting chemist.

Dunn, John, Morgan Academy, Dundee, science teacher.

Foden, Alf., 52, Everton Valley, Everton, Liverpool, analytical chemist.

Holloway, G. T., 17, Bridge Road West, Battersea, S.W., analytical chemist.

Jones, Wm., 61, Chadwick Road, Peckham, S.E., analytical chemist.

Keys, W. H., Hall End Chemical Works, West Bromwich, chemical manufacturer.

Lampray, R. H., 24, Bughley Road, Highgate Road, N.W.

Matheson, W. J., 178, Front Street, New York, U.S.A., chemical and dye merchant.

Mitchell, Jas. Vernon, 12, Woodstock Street, Oxford Street, London, W., chemist.

Pennoek, J. D., Solvay Process Co., Syracuse, N.Y., U.S.A., chemist.

Platts, Jno. C., 25, Harecourt Road, Crookesmoor, Sheffield, metallurgical chemist.

Roberts, Chas. F., 48, Vicar Lane, Bradford, Yorks, chemical merchant.

Robey, Chas. M., Collingwood, Ontario, Canada, tanning chemist.

Rogerson, W. J., 38, Southwark Street, London, S.E., wholesale druggist.

Sayers, Jos. J., Nobel's Explosives Co., Ardeer, Steveston, N.B., chemist.

Shutt, Frank T., Central Experimental Farm, Ottawa, Canada, chemist.

Smith, J. Wm., Solvay Process Co., Syracuse, N.Y., U.S.A., works manager.

Storer, Dr. John, 163, Clarence Street, Sydney, New South Wales, consulting chemist.

Tucker, Greenleaf R., City Hospital, Boston, Mass., U.S.A., chemist.

Waterhouse, Col. Jas., 45, Chowringhi Road, Calcutta, assistant surveyor-general of India.

Wynne, W. P., 8, Elthiron Road, Fulham, S.W., lecturer on chemistry.

#### CHANGES OF ADDRESS.

Aldred, C. H., 1/o Crisp Terrace; 6, Heavitree Road, Plumstead Common, Kent.

Belcher, J. C., 1/o Wool Exchange; Chemical Department, Royal Naval College, Greenwich, S.E.

Berry, E. E., 1/o Bucklersbury; Much Hadham, Herts.

Boyd, Wm., 1/o St. Rollox; 6, Broompark Terrace, Dennistoun, Glasgow.

Broom, Wm., 1/o Herberton; Mount Albion, North Queensland.

Brunner, Dr. P., Journals to 29, Fenney Street, Higher Broughton, Manchester.

Campbell, Archd., 1/o Upton Park; North British Chemical Co., Clydebank, near Glasgow.

Chauncy, H., Journals to c/o Mysore Gold Mining Co., Lim., Kolar Road, Mysore, India.

Claudet, F. G., 6, Coleman Street, E.C.; Journals to 3, Manor Rise Terrace, Dulwich, S.E.

Cliff, Cromwell, Journals to 30, Trentham Street, Runcorn.

Cliff, D. Y., 1/o Wellington Street; 14, Royal Exchange, Leeds.

Collins, J. H., 1/o Clarke Terrace; 60, Heber Road, Dulwich Rise, S.E.

Cooper, H. P., 1/o Haringay Road; 11, Fairmead Road, Upper Holloway, N.

Crichton, D. G. (Journals), P.O. Box 1016, Sydney, New South Wales; (subs.) Logan Bank, Cupar Fife, N.B.

Hake, C. N., 1/o Westminster; c/o Minister of Mines, Melbourne, Victoria.

Heaton, Prof. C. W., Journals to 44, Woodstock Road, Bedford Park, W.

Hodges, J. F., 1/o Belfast; Tudor Park, Holywood, co. Down, Ireland.

Hutchinson, H., 1/o Dulwich; 14, College Avenue, Lower Clapton Road, E.

Jackson, A. G., 1/o Sydney; G.P.O., Brisbane, Queensland.

Kay, W. E., 1/o Thornliebank; Gowanbank, Busby, near Glasgow.

Kemp, W. Joel, Journals to Fern Cottage, East Croydon.

Kitamura, Y., 1/o Brunswick; c/o Herrn O. Höfel, Werftstrasse 10, Moabit, Berlin.

Lewis, J. H., 1/o Widnes; Oakleigh, Stanwell Road, Penarth, Cardiff.

Miller, Dr. A. K., 1/o Kirkintilloch; 28, Delaunays Road, Crumpsall, Manchester.

Payne, Geo., 1/o Wakefield; Andover Villa, Tivoli, Cheltenham.

Redwood, I. J., Journals to Shern House, Walthamstow, Essex.

Redwood, Dr. T., Journals to Shern House, Walthamstow, Essex.

Stocks, H. B., 1/o Nuttall Street; 25, Ferndale Road, Smithdown Road, Liverpool.

Sutherland, Jno., 1/o Flinder's Lane; Elsternwick, near Melbourne, Victoria.

Terry, Albert, 1/o Melbourne; Drayton, Wellington Street, Kew, Victoria.

Wainwright, Dr. J. H., 1/o Washington Street; 22, West 46th Street, New York, U.S.A.

Wood, Wm., Journals to 124, Chaussée de Turnhout, Antwerp.

#### MEMBER OMITTED FROM LIST.

Pratt, J. W., c/o Pratt and Co., Mobile, Ala., U.S.A.

### Death.

Muter, Jas., at Rangoon, Burmah, September 19, 1889.

## London Section.

### CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: David Howard.

Committee:

Sir F. A. Abel.	R. Messel.
H. E. Armstrong.	B. E. R. Newlands.
W. Lant Carpenter.	B. Redwood.
W. Crowder.	T. Royle.
W. J. Dibdin.	John Spiller.
C. Graham.	Wm. Thorp.
S. Hall.	C. R. Alder Wright.
C. C. Hutchinson.	

Hon. Local Sec. and Treasurer: Thos. Tyrer, Battersea, S.W.

#### SESSION 1889-90.

1890.

April 21st (extra meeting):—

Dr. E. R. Moritz. "Note on the Expulsion of Ammoniacal Compounds from Sulphuric Acid used in Kjeldahl determinations."

Mr. Boverton Redwood. "The Petroleum Fields of India."

May 5th:—Mr. Wm. Webster. "The Electrical Treatment of Sewage."

June 2nd:—Dr. W. S. Squire. "The Artificial Production of Cold theoretically and practically considered."

July:—Annual General Meeting in Nottingham.

Meeting held Monday, 3rd March, 1890.

MR. DAVID HOWARD IN THE CHAIR.

### THE EXAMINATION OF TEXTILE FIBRES AND FABRICS.

BY H. SCHLICHTER, D. SC. NAT.

In the first place my paper does not pretend to be an account of the constitution of textile fibres. This branch of the subject has already been dealt with by Chevreul, Grothe, Cramer, Schulze, Hugo Müller, Mulder, Schützenberger, Bourgeois, and others; but this paper is intended to describe methods by which chemists may identify and distinguish various textile fibres, and estimate them quantitatively in textile fabrics. Moreover, the paper is limited to such textile fibres as find practical application in the European manufacture of textile fabrics, among which I do not include paper.

The technical examination of fibres and fabrics has hitherto been dealt with systematically only to a very limited degree, although there exist a number of more or less elaborate monographs, mostly based on microscopical studies, in which may be found at intervals valuable material in the shape of descriptions of reactions, properties, and measurements. Many of these, however, are merely colour tests, applicable only to undyed or raw fibres.<sup>(1)</sup>

Among the authors who may be regarded as having contributed to the literature of this subject are the following, to whose names we append the titles of their works:—

Schacht: Die Prüfung der im Handel vorkommenden Gewebe, 1853.

Schlesinger: Mikroskopische Untersuchungen der Gespinnstfasern, 1873.

Höhnel: Die Mikroskopie der technisch verwendeten Faserstoffe, 1887.

Kölliker: Mikroskopische Anatomie, 1850.

Kölliker: Gewebelehre, 1852.

Leydig: Histologie, 1857.

Nathusius: Wollhaar des Schafes, 1866.

(1) See note (25)

- Wiesner: Technische Mikroskopie, 1867.  
 Wiesner: Mikroskopische Untersuchungen, 1872.  
 Wiesner: Rohstoffe des Pflanzenreiches, 1873.  
 Bolley: Technologie der Spinnfasern.  
 Bohm: Wollkunde, 1873.  
 Grothe: Technologie der Gespinnstfasern, 1875.  
 Grothe: Die Gespinnstfasern aus dem Pflanzenreiche, 1879.  
 Vétillart: Études sur les fibres végétales textiles, 1876.  
 Bowman: The Structure of the Cotton Fibre, 1881.  
 Bowman: The Structure of the Wool Fibre, 1885.  
 Christy: New Commercial Plants and Drugs, No. 6, 1882.

In many of these works we find little or no trace of a systematic treatment of the subject, but here, as well as in other publications not cited, we find notices on the properties of various fibres. When we realise the practical importance of the textile industries of this and other European countries, it is very difficult to understand why up to this time no *general scheme* of analysis in this branch of science has ever been worked out.

It would lead me too far now from my actual subject to deal with that question in a comprehensive way, and I will therefore mention only one important reason, viz., the fact that studies and inquiries about the proximate investigation of textile fibres and fabrics up to the present day are regarded as belonging much more to the province of botany, histology, or zoology, than to that of analytical chemistry.<sup>(2)</sup> From the practical point of view of textile industry, I hold quite an opposite opinion, and I have now to describe a system for the examination of textile fibres and fabrics, so as to ascertain their proximate constituents, which I think is convenient for all practical purposes.

A laboratory to be used for the examination of textile fibres and fabrics must be somewhat differently fitted up from that which is required for general chemical analysis; but although the microscope is a most important instrument for our purpose, it must not be regarded as the only means of making observations of this kind, as many have thought. It is the continuous working into one another of microscopy and chemistry, or, better expressed, of microscopical and macroscopical chemistry, that is the special characteristic of all investigations upon textile fibres and fabrics.<sup>(3)</sup> Any good microscope can be used for the purpose. I, however, especially recommend the use of one having revolving nose-pieces for rapidly changing the objectives, an arrangement which is coming more and more into general use. Furthermore, it is of importance, in making certain special observations, to use the well-known illuminating apparatus by Abbé<sup>(4)</sup> in conjunction with the microscope. It is self-evident that a micrometer is absolutely necessary for measuring the dimensions of the fibres. As I proceed I shall describe the reagents which have to be used, partly in connexion with the microscope and partly without it. Besides, there is especially one other kind of instrument which must be a chief feature in a laboratory for the examination of textile materials, i.e., an apparatus for determining the moisture of the fibres.

(2) The most important works of Wiesner, Vétillart, Nathusius Bowman, &c. tend in the direction of botany, histology, or zoology. See Wiesner, "Rohstoffe," p. 298, and Hugo Müller, "Pflanzenfaser" (in the Vienna Exhibition Reports), pp. 6 and 23.

(3) At any rate this is my own experience, after a long time of practical work on this subject. I was glad to find a similar opinion expressed by Cross, Bevan, and King in their "Report on Indian Fibres and Fibrous Substances," 1887, in the following passage, p. 2: "These authors (viz., Hugo Müller and Vétillart) have kept in the main to a distinct line of investigation, chemical or microscopical, only incidentally introducing the other, its essential complement. A method compounded of the two lines of inquiry must necessarily give a more complete account of the subject-matter, and this we think will be found from the method about to be described." Now, on Hugo Müller's negative view on *chemistry alone* for the distinction of vegetable fibres from one another, see his "Pflanzenfaser," p. 23; therefore it might be expected that microscopy would have an essential part in all investigations, but with reference to the most important vegetable fibres, this is by no means the case in the above-named Report, *cotton* and *flax* being treated quite insufficiently, and *hemp* not at all. This is much to be regretted when we consider what difficulty may arise in distinguishing hemp and flax fibres from each other. (See Schacht, Wiesner, Vétillart, Cramer, and Hohnel.)

(4) The instrument used by me is constructed by Zeiss, in Jena.

All textile fibres are hygroscopic,<sup>(5)</sup> some of them in a very high degree, and it is not sufficient to apply to them the methods which are used in general chemical analysis, because it is for practical purposes necessary to work with larger quantities (as regards weight and volume), in order to get the exact average of moisture.<sup>(6)</sup>

The apparatus<sup>(7)</sup> for such determinations is constructed in such a way that the substance to be dried is suspended in hot air of about 108° C., the air passing through the apparatus in a continuous current. Above the hot air chamber a chemical balance is fixed, an arrangement by which it is possible to weigh the substance while it is in the interior of the apparatus.<sup>(8)</sup> This offers two advantages; the precise moment can be ascertained when perfect dryness is attained, and, secondly, the prevention of re-absorption of moisture. It is of course understood that during the process of weighing the current of air has to be stopped.

All textile fibres are divided into three chief classes:

1. Those of vegetable origin;
2. All animal wools and hair; and
3. The different kinds of silks.

Now, if we get any textile material of unknown composition, the first fundamental experiment which we have to make is to examine some simple microscopical water objects of the material. If the substance is a raw product, a loose material, or a yarn, these objects are taken from different parts of the said material, but if we have a ready-made article, then the different parts of it have to be examined separately, e.g., in rectangular textures, the warp and the woof.<sup>(9)</sup>

The simple microscopical properties of the textile fibres as they present themselves to the eye, moderately magnified, are well known, as follow:

The fibroine fibres of all silks are uniform, and either entirely of a homogeneous structure, or show simple longitudinal lines.

The fibres of animal wool and hair have either characteristic scales on their surface, or a central medulla, or both of these properties; and as regards vegetable fibres, which exist in a great number of different forms, the most important of them are characterised by their *lumen* (central cavity of these fibres), and in a negative sense they are marked by the absence of the qualities which we have seen to be characteristic of wool, hair, and silk.

But a knowledge of these simple characteristics is not sufficient, for fibres are inclined to vary. Natural causes as well as changes produced by artificial influences can affect the appearance and the qualities of the fibres in various ways,<sup>(10)</sup> the artificial influences being produced by the different kinds and modes of manufacturing. Hence it follows that it is necessary to assist microscopical examinations by chemical reagents.

First, let us observe the influence which cold concentrated sulphuric acid has upon fibres. If they are immediately dissolved by the acid, and little or nothing remains, then the substances are either silk or vegetable, or a mixture of both. But if the fibres are not rapidly dissolved, and epidermal scales appear standing out from the surface, we have wool or hair before us.

Secondly, let further microscopical objects be subjected to the action of cold concentrated hydrochloric acid. The fibres will be dissolved if real silk is the object acted upon, but should vegetable fibres, animal wool or hair, and Tussah silks<sup>(11)</sup> be the objects, the fibres will remain unchanged by the action of the said acid.

A = Hot air entrance.

B = Hot air exit.

C = Basket to contain material for experiment.

This apparatus, the invention of M. Storhay, has been modified in various particulars by Mr. Hermann Schlichter and myself. By using Perret's heating system, it can be maintained at a constant temperature for hours without danger of injury to the fibres.

Thirdly, let a piece of the material to be experimented on be boiled for 10 minutes in a solution of 10 per cent. of caustic potash or soda, and then carefully rinsed and washed several times. The fibres of all kinds of silks, of wool, and hair are by this treatment dissolved,<sup>(12)</sup> but should anything remain, then the fibres can consist only of vegetable matter, the nature of which has to be ascertained by the microscope.

Finally, we have to ascertain the presence or absence of Tussah silks. For this purpose boil a piece of material for a short time in concentrated hydrochloric acid, and examine it microscopically. If a quantity of small but clearly defined portions of fibres manifest themselves with sharp and straight terminals, which very often show longitudinal lines, the presence of Tussah silks is proved.<sup>(13)</sup> Of course, other fibres may also be present, but this does not interfere with the reaction.

I now proceed to the quantitative distinction<sup>(14)</sup> of the several classes. For this purpose we take a piece of material, weigh it and put it into the drying apparatus, and as soon as it is entirely desiccated, weigh it a second time. By this means we find the hygroscopic moisture of the fibres. Then by boiling dyed and ready-made materials in highly diluted hydrochloric acid, we ascertain the amount of colouring matter, finish, dressing, &c.

Thirdly, we have to examine separately the various constituents found to be present by the preceding qualitative tests. If the substance is a mixture of *silk and wool*, we can dissolve the silk fibres in it with concentrated hydrochloric acid, or with dilute sulphuric acid, and the wool will remain unchanged. After thoroughly washing them, we dry and weigh the remaining fibres, which will give us the amount of wool, that of silk being ascertained by subtraction. But if we have a combination of *silk and vegetable fibres*, the silk can be dissolved only in hydrochloric acid, and the result is obtained by proceeding as in the last experiment. Finally, *wool and plant fibre* combined are separated in a similar way, viz., by boiling the material in a weak solution of caustic potash or soda, wool being dissolved.

But should we have a compound of the three substances, wool, silk, and plant fibre together, we must proceed as follows:—Wool and silk are simultaneously dissolved by caustic potash or soda, and the unaffected remainder will, of course, be vegetable fibres. Again, another piece of the same material being taken, we dissolve the silk and vegetable fibres by a weak solution of sulphuric acid, leaving the wool unaffected. The amount of silk is ascertained by subtraction. Of course, all weighings have to be made when the fibres are in a perfectly dry state.

Having now solved the preceding problems we come to more detailed ones of the several classes before us. And this is the especial province of the microscope, for there are differences which can never be discovered by macroscopical means, owing to the similarities<sup>(15)</sup> existing in a great variety of substances. Let us begin with the **VEGETABLE TEXTILE FIBRES**. Only a limited number of them find at the present time extensive application in the European manufacture of textile fabrics,<sup>(16)</sup> and I therefore confine my remarks to the most important representatives of this class. Of course the most important is *Cotton*. As a general rule the different kinds of cotton fibres are flat (band or ribbon-like), with a plainly discernible lumen; and they have a peculiar way of being twisted corkscrew-fashion.<sup>(17)</sup> Whilst the cotton fibre is a kind of vegetable hair, *Flax* is a

bast fibre of the linum, and is distinguished from cotton by its round or polyedric cross-section. The lumen of flax is narrow, and the fibre, as in cotton, consists for the most part of pure cellulose. Again, flax fibre frequently shows joints transversely to the fibre, giving it an irregular and chain-like appearance.

The bast of *Hemp* is of similar construction to flax, but its cells are more irregular, its cell walls more resisting, and the lumen is sometimes of varying dimensions. But these peculiarities are not sufficient to show with accuracy and promptness the true differences between flax and hemp, for there are many flax fibres, especially those taken from the lower part of the stem, which are so very similar to hemp fibre that the one cannot even microscopically be distinguished from the other.

While pure flax fibre consists mostly of cellulose, and—in case of undyed fibres—with iodine and sulphuric acid gives a blue reaction, hemp in part contains woody substances, and therefore with the just named reagents may give green or yellow colours.<sup>(18)</sup> But this reaction is by no means general and conclusive, for there are many hemp fibres which show exactly the same result, as cotton and flax, in blue.<sup>(19)</sup> Therefore attempts have been made to find the difference between the fibres by micrometric observations of their diameters, but unfortunately without any really satisfactory result.<sup>(20)</sup> A further distinguishing feature was supposed to exist in the appearance of the ends of the fibres in their natural state:<sup>(21)</sup> those of flax being assumed to be single, while those of hemp were thought to be double pointed. But then this difference is only partially correct, for many hemp fibres have been found terminating like flax in a single point.<sup>(22)</sup>

Finding all this insufficient to establish a true proximate analytical difference between flax and hemp, I tried another method which I found to give good and accurate results. The lumen of flax fibre always contains a certain amount of protoplasm<sup>(23)</sup> which is not destroyed by sulphuric acid, as cellulose is, but remains unchanged. Now the lumen of hemp very rarely shows the presence of protoplasm,<sup>(24)</sup> and hence hemp and flax fibres are very easily distinguished in this way, the one from the other. Some microscopical objects subjected to the action of sulphuric acid of 75 per cent. will solve the question without difficulty. In both cases the cellulose of the fibre is quickly destroyed by the action of the acid. In the case of flax there remains the protoplasm of the lumen as a most distinctly marked line or narrow ribbon; whilst hemp shows nothing of this, but is quickly reduced to a more or less shapeless mass.

I find this method to be still easier and give better results if iodine is used previous to the application of sulphuric acid. Of course this is possible only when the material to be tested is *without dye*. I have referred to the reaction of iodine and sulphuric acid, which is well known as being highly characteristic for vegetable fibres.<sup>(25)</sup> It is for one reason only not of *general* importance for the proximate analysis of fibres and fabrics, as it can be applied only to undyed fibres.<sup>(26)</sup>

(13) See Schacht, *Gewebe*, p. 25.

(14) See the micrometric measurements in Vétillard, *Études*.

(15) See Schacht, *Gewebe*, pp. 21, 23, and 26, and compare Hohnel, *Mikroskopie*, pp. 37–39.

(16) See Schacht, *Gewebe*, Table VI., Fig. 4, a; Vétillard, p. 77 and Table 7; Wiesner, *Techn. Mikroskopie*, p. 110, and Rohstoffe, p. 376; Schlesinger, *Gespinnstfasern*, p. 26; Cramer, *Programm d. Zurich Polyt.*, 1881.

(17) See Vétillard, *Études*, Table 7; Hohnel, *Mikroskopie*, pp. 35 and 36; Hugo Müller, "Pflanzenfaser," p. 38.

(18) See Schlesinger, *Gespinnstfasern*, Table, pp. 14–15; Wiesner, *Rohstoffe*, p. 390.

(19) Colour reactions—such as reactions with iodine, phenol, phloroglucin and indol, nitric and picric acid, plumbite of soda, stannic chloride, sulphate of aniline, &c., &c.—have hitherto been used to a great extent in distinguishing fibres. This is correct as long as the fibres are in a raw state, or are found in undyed materials. But as soon as the fibres are dyed, bleached, &c., as is well known to be the case in a vast number of textile fabrics, then the colour reactions vary considerably. Hugo Müller and Hohnel share this opinion. It is for these reasons that I have avoided colour reactions as much as possible in my general analytical treatment of fibres, and substituted acids and alkalis as reagents. The above-named reaction of iodine and sulphuric acid refers to a special case, as is stated expressly.

(12) See Schacht, *Gewebe*, pp. 18 and 30.

(13) At any rate, this is my own experience. About the collective name "Tussah Silks" see Hohnel, *Mikroskopie*, p. 150.

(14) See Remont, *Jour. Pharm. Chim.*, 1880; *Chem. News*, No. 1294; *Jour. Soc. Chem. Ind.* 1882 and 1884; and Persoz, *Compt. Rend.*, 55.

(15) See Bowman, *Structure of the Wool Fibre*, p. 127; *Grothe*, *Gespinnstfasern*, p. 1; Wiesner and Praseh, *Seiden*, *Micr. Unt.*, p. 54; and others.

(16) See Vétillard, *Études*, p. 252; Cross, Bevan, and King, *Report on Indian Fibres*, p. 1.

(17) Cotton may always be recognised very easily by these generally known features, no difficult investigation being necessary. See Bowman, *Structure of the Cotton Fibre* (plates); Hohnel, *Mikroskopie*, pp. 26 and 27; Vétillard, p. 141; Schacht, *Gewebe*, pp. 23 and 24.

I find that it is, as a rule, insufficient and unsatisfactory to use solutions of one degree of strength in all experiments as has been hitherto the rule exclusively,<sup>(26)</sup> for the best results are often lost owing to the improper strength of the reagents. I therefore recommend the following:—The solution of iodine to be always the same, and consist, e.g., of 1 part of potassium iodide in 100 parts of water, to which solution iodine is freely added.<sup>(27)</sup> But the sulphuric acid must be used in different degrees of strength. I use, for instance, a series of 25, 30, 40, &c., up to 90 per cent. of pure concentrated sulphuric acid.

I will now mention very briefly some other vegetable textile fibres<sup>(28)</sup> which are of more or less practical importance in addition to cotton, flax and hemp<sup>(29)</sup>.

*China grass* consists of bast fibres, the form of which is rather irregular, partly ribbon-like, partly round and with a lumen varying in size. It never appears under the microscope rolled up in a corkscrew form, as is the case with cotton.

*Jute* is another kind of bast fibre material. The lumen often varies in width, a sign by which the fibre is easily distinguished from others.

*New Zealand flax* is a fibre obtained from the leaves of the plant producing it. It consists of cells, sharply pointed at the terminals, and circular in cross-sections, the lumen and cell-walls being uniform throughout.

We now proceed to the second of our classes, viz., the different kinds of SILKS. Ordinary raw silk consists of double fibres which are coated with the so-called silk gelatine,<sup>(30)</sup> which is not a part of the fibre itself, and must be subsequently removed by boiling either in water or soap. The fibre throughout is a homogeneous and cylindrical body of fibroine. Besides genuine silk, other kinds of fibres of similar origin have been introduced into the silk trade, known by the collective name of *Tussah silks*.<sup>(31)</sup> They may be distinguished from genuine silk by various features.

First, it must be stated that their diameters are totally different,<sup>(32)</sup> that of real silk being much smaller and more uniform than that of Tussah silks.

Secondly, these last silks show distinctly longitudinal lines in their fibroine fibres,<sup>(33)</sup> and also often colouring matter in the same,<sup>(34)</sup> these properties being absent in real silk.

Thirdly, a special property of Tussah silks is the uneven thickness of the single fibres.<sup>(35)</sup> Genuine silk is quite uniform in this respect.

And lastly, in certain Tussah silks characteristic bands cross the fibres in an oblique direction,<sup>(34)</sup> the fibres appearing of a lighter colour in these bands. They originate in two fibres crossing each other in the cocoon before they have become hard. If the contact takes place after the fibres have hardened, no bands are of course produced, and either the frequent appearance or the absence

of the same is characteristic of many though not of all these silks, and forms another feature by which they may be distinguished from genuine silk. We see there is no difficulty in distinguishing real silk from other kinds, but, if we wish to classify the silks, the best method is the micrometric measurement of their diameters. But until now this was possible only in a very incomplete manner, for the diameters of Tussah silks are very variable, as I have remarked before. Attempts have therefore been made to find the greatest diameter of any single fibre.<sup>(35)</sup> This may be done in a few instances, but to continue the operation each time in 20 or 30 cases with accuracy, and strike an average of the whole, is a practical impossibility. I have, however, found that genuine silk as well as all other kinds, if treated with caustic potash (Tussah silks may also be treated with hydrochloric acid), fall into a great number of very small particles which completely retain their original structure, and show sharp and straight terminals. These small particles are admirably adapted for an easy and perfectly accurate determining of the diameters, and besides this they show the narrower parts of the fibres in a marked manner.

I found a peculiar passage in the second volume of the Journal of this Society, pp. 172—173. Reference is made there to certain colour appearances of the different kinds of silk. This passage is wholly unintelligible, for there can only be a question of polarised light, but this is not stated there. I do not know whether this inaccuracy has since been rectified, and I only mention the matter in case no such correction has been made.

The third of the classes of textile fibres is composed of all sorts of ANIMAL HAIR AND WOOL, the most important of which is the wool of the sheep. Hair and wool may be generally described as compounded of three different parts:<sup>(36)</sup> the innermost is a cylinder containing the medulla, next comes a horny stratum of fibre, and externally is a scaly layer of epidermal cells. According to the nature of the wool one or the other of these parts may be wanting, or may be of less importance. In many, especially the fine sheep wools, the innermost stratum—that containing the medulla—is absent, and the fibre gains thereby in uniformity and firmness.<sup>(37)</sup>

Amongst all animal fibre *sheep's wool*, of course, takes the first rank in practical importance. There are a great many varieties of sheep's wool,<sup>(38)</sup> as is well known, but all being absolutely equal in substance, the analytical investigation must be of an almost exclusively microscopic nature, chemical reagents finding only a subordinate place in their examination.

1. *Coarse wools*, in which many thick hairs are found in conjunction with the fine wool. The former are characterised by a thick central medulla, which constitutes the greater part of the fibre. In this class of wool the finer fibres differ materially from one another, and show no uniform features.

2. The so-called "*landwollen*,"<sup>(39)</sup> in which the finer fibres more predominate as in coarse wools, though thick hairs are always present. The finer fibres of this wool are frequently bent in an abrupt and irregular manner, and the diameters of single fibres are unequal.

3. The type of the *crossbred wools* has very long and strong fibres with very little inclination to curl. The fibre scales are very conspicuous, and the character of the wool itself is beautifully uniform, though the fibres are coarser than that of fine merino wools. A further characteristic feature is the absence of the medulla.

The so-called Lincoln and Leicester wools are relatives of the crossbred wools, to which they correspond in many respects. The medulla, although frequently absent, is not entirely so.

4. The most important and finest quality of all kinds of sheep's wool are the *merino wools*. The thinness, fineness, and uniformity of their fibres (coarse and stiff hair

<sup>(26)</sup> See Schacht, Gewebe, p. 8; Schlesinger, Gespinnstfasern, pp. 6 and 12; Wiesner, Rohstoffe, p. 300; Vétillart, Études, pp. 28—29; each observer giving his own recipe.

<sup>(27)</sup> See Vétillart, Études, p. 28.

<sup>(28)</sup> Cross, Beran, and King (Report on Indian Fibres) seem to attach particular analytical importance to the lengths of the ultimate fibres. But although this is of high morphological importance, it is not of the slightest value analytically, because it is a practical impossibility to measure the lengths of fibres after they are spun into yarns and woven into textiles; especially when such fibres are many hundred times longer than broad (See Wiesner, Vétillart and Bowman). Wiesner, e.g., has made the most minute investigations upon the lengths of fibres, and places particular morphological importance on it, but he does not use it in the analytical distinction of fibres. See Wiesner, Rohstoffe, p. 238 "Kennzeichen der Fasern;" p. 343, on distinction of cotton and flax; p. 375, of flax and hemp; p. 395, of jute, flax and hemp.

<sup>(29)</sup> Of the few following vegetable fibres only the chief characteristic features are given, because they are not of the same general importance as cotton, flax and hemp. Next to these comes jute, of which however Vétillart says (Études, p. 252): "Le jute ne se recommande par aucun autre avantage que son bas prix et la facilité avec laquelle on est arrivé à le filer."

<sup>(31)</sup> See Hohnel, Mikroskopie, p. 150.

<sup>(32)</sup> See Schlesinger, Gespinnstfasern, p. 42, and Hohnel, Mikroskopie, p. 152.

<sup>(33)</sup> See Schlesinger, Gespinnstfasern, pp. 42—44; Hohnel, Mikroskopie, pp. 114 and 145.

<sup>(34)</sup> Wiesner and Prinsch, über Seiden, Mikr. Unt. pp. 45—54; Hohnel, Mikroskopie, p. 152.

<sup>(35)</sup> Schlesinger, Gespinnstfasern, p. 42.

<sup>(36)</sup> See Bowman, Wool Fibre, Plates V. and VI.

<sup>(37)</sup> See Grothe, Technologie der Gespinnstfasern, p. 18.

<sup>(38)</sup> See the admirable treatment of this subject in Bowman, Structure of the Wool Fibre.

<sup>(39)</sup> There seems to be no special expression for this type of wools in the English language, at least I could not get a collective name from practical people in the wool trade.

being entirely wanting) may be mentioned first. The total absence of the medulla is another feature connected herewith. Furthermore, the manner in which the epidermal scales are arranged is also characteristic. For, these cup-like scales fit one into the other, foot into mouth, and consist of one piece.<sup>(40)</sup> In other wools this is not the case, for the fibres are not encircled by one single scale, but always by a combination of several scales.

As I have previously stated, hair and wool of all other kinds of animals are of much less importance in the manufacture of textiles than sheep's wool. But I might briefly state the ways in which some of the said wools and hairs differ from each other. The wools of the *Angora goat* (41) consist of a mixture of fine wool and coarse hair; they are comparatively stiff, uncurled, uniform, and covered with flat scales. The hair is characterised by the thick medulla in the middle, which gets gradually and uniformly thinner towards the top of the fibre.

Similarly constituted is *alpaca wool*, which is not curled, and is found usually in dark or black varieties. When black, the fibres are too opaque to allow anything of their structure to be discerned. But gently warmed with sulphuric acid of 60 per cent. strength, the scales separate from the body of the fibre; the fibres become partly lighter and semi-transparent, and it can easily be observed that the original colour which, prior to the application of the acid, seemed to be uniformly black, is really a thick layer of natural brown colouring matter.

Very different from these are the thin, fine, and uniform fibres of *vicunna wool*, which are similar to camel wool and appear without scales. They are likewise not curled. In addition to fine fibres the vicunna wool contains thick hair which shows a strong medullar development. The fibres throughout manifest much natural brown colouring matter.

What is called *camel hair* is also a mixture of coarse hair and fine wool. The fine wool fibres are characterised in part by their having medullar cells or tubes. The difference of the development of the medulla in the coarser hair is furthermore characteristic, as it usually appears in all degrees and varieties. Camel hair always contains natural brown colouring matter in different degrees of intensity, varying from almost white to dark brown.

I have mentioned several times that textile fibres may contain certain quantities of natural colouring matter in their cells. In vegetable fibres and silks such colouring matters are practically only of subordinate importance, but in many cases it is essential to discover whether the brown colour of certain hairs or wools is natural, or has been given them by dyeing. It is not possible, however, to ascertain this by an ordinary microscopical observation,<sup>(42)</sup> and although the natural colour will offer a greater resistance to reagents than artificial ones do, this property is by no means a general one. Moreover, as brown is the predominant shade of all nature-coloured animal fibres, and this tint has few microscopical varieties artificially, this fact tends to make the matter still more difficult. But I may say I have found a practical and very simple method by which the natural and artificial colours of hair and wool can be distinguished the one from the other. For this purpose a microscope with Abbé's illuminator attached must be used. For a general examination of textile fibres diaphragms with the smallest apertures must be employed with this instrument, in order to observe the structures of the fibres. But if animal fibres have to be examined, whether they are of a natural colour or not, the objects must first be treated with a cold solution of caustic potash or soda, in order to produce swelling, by which the different parts and strata of the fibres become clearly visible.

Now, if such objects be brought under the microscope and the diaphragms of the illuminator entirely removed, so that the whole aperture of the objective is filled by rays of light, then we get a view of the fibre which does not show much of its structure, but presents the colour reactions so much the better. For, if the colour is an artificial one, the fibre

appears to be a homogeneous and uniformly dyed body; but if the colour is natural, we perceive the colouring matter arranged in a peculiar way in certain parts of the fibre, forming there longitudinal stripes or lines, consisting of small points or grains, and this arrangement is so characteristic that a mistake is absolutely out of the question.

Another material which needs a peculiar method of examination is *shoddy*, which is used in conjunction with good wool. It is well known that large quantities of old woollen articles and cuttings, rags, &c., are worked up again, spun and woven a second time, and reappear in the market. Enormous quantities of shoddy are now annually produced in Great Britain and on the Continent, and because it is generally four or five times cheaper than new wools are, we can form an idea of the practical importance of the shoddy trade. But this introduction of shoddy into textiles is not always done "in good faith," but often the said material is palmed off as good wool, and the public pays for it a much higher price than it is worth. In fact, a great many materials, especially those made of short wools, are more or less adulterated with shoddy. From this fact we may learn the great importance of having correct analytical methods of proving the amount of shoddy in textiles. But to accomplish this many different things have to be observed, in order to test fibres whose structure and chemical properties differ from good wool only to a certain degree.

None of the methods (43) known hitherto gave correct results, and therefore I apply my own test, which is as follows:—

All kinds of shoddy contain more or less vegetable fibres which are always to be found in old woollen articles, rags, &c., and which cannot be totally removed chemically from shoddy without damage to the shoddy. Frequently these vegetable fibres are dyed with different colours, according to their different origin. Now, after having made the tests to discover vegetable fibres in general, a piece of the material, which should be as large as practically possible, is weighed, then cut into pieces, and each of these pieces beaten in a mortar arranged for the purpose. Then the pieces are brushed on a specially prepared board, and what is brushed off is carefully collected. This having been done, the pieces are weighed again.

By this process a part of the shoddy is removed from the material, of course partly mixed with fibres of good wool, but these are brought into account, as we will see at once. The next step is, to examine the brushed off fibres most carefully under the microscope. Here shoddy always shows a great variety of features which are absent in good wool.

The most striking of these are:—

1. Wool fibres of differently dyed colours.
2. Damaged wool fibres.
3. Vegetable fibres, partly dyed.
4. Small particles of wool fibres with brush-like ends.
5. Absence of epidermis of the wool fibres.

To these features others may come according to circumstances. I repeat, a most minute and careful microscopic examination is necessary, in order to decide all these points. This examination also shows us the proportion of the shoddy fibres to the good wool fibres in these brushed off parts. Then these parts, as well as the pieces of the material from which they were brushed, are dissolved in caustic potash or soda, each separately, the solutions filtered through fine platinum filters, and the vegetable fibres collected in both cases from the filters. The amount of these vegetable fibres is then ascertained in both cases either by weighing, or by microscopical measurements.

Now experiments show that such vegetable fibres are always found uniformly divided in shoddy, and therefore we have the following calculation:—

1. Original weight,  $a$ .
2. Weight of brushed pieces,  $b$ .
3. Weight of brushed off fibres,  $a - b$ .
4. Amount of shoddy found by microscopic estimate in the brushed off fibres  $\frac{1}{x}$  of the total amount of these.

(40) Watson Smith, this Journal, 1889, 20, Figs. 8 and 9.

(41) Bowman, Wool Fibre, Plate 28.

(42) See Höhnel, Mikroskopie, pp. 90 and 101.

(43) See Schlesinger, Gespinnstfasern, p. 62; Höhnel, Mikroskopie, p. 107; Focke, Arch. d. Pharm., Vol. 24, p. 619. Höhnel's method is the best of these, but it cannot be applied for quantitative determinations of shoddy.

5. Proportion of vegetable fibres in brushed off parts to vegetable fibres in brushed pieces 1 :  $m$ .

Then it is evident that  $m$  times as much shoddy is contained in the brushed pieces as in the brushed off fibres, and therefore the total weight of shoddy in the material is  $\frac{a-b}{x} + m \frac{a-b}{x} = \frac{a-b}{x} (1+m)$ ; and the percentage of shoddy can easily be calculated from this.

I point out again that the factor  $\frac{1}{x}$  is based on a microscopical estimate, the more exact this is, the more exact will be the final result.

It would remain for me to deal with the most important *hygroscopic properties* (<sup>44</sup>) of textile fibres and fabrics, and their analysis, as well as the analytical treatment of *raw products*, especially *raw wool* (<sup>45</sup>) which contains, as you are well aware, besides moisture, a large amount of accessory substances, such as grease, sand, dust, burrs, &c. But this subject is too important to be treated only briefly at the end of this paper. Perhaps I may have an opportunity of dealing with it another time.

In conclusion I should like to mention that I am indebted to my brother, Mr. Hermann Schlichter, for the illustrations which appear with the paper. The drawings of the fibres have been made from microscopic observations, unless otherwise noted.

#### DISCUSSION.

The CHAIRMAN said that the very perfection of the gravimetric and thermometrical methods of analysis, as also the perfection of the microscope, was apt to constitute a source of danger. The chemist was accustomed to think that everything that could be known in chemistry was to be learnt by means of the balance and the burette; while the microscopist hardly considered that knowledge which could not be demonstrated by the microscope. Dr. Schlichter's paper dealt with one of those wise combinations of purely chemical and purely physiological methods which indicated the great possibilities of the progress of scientific investigation. It was by such mixed methods that immense progress could be made in arriving at approximate analyses. Of the commercial value of accurate analyses it was impossible to speak too highly. The triumphs of shoddy were wonderful; and to be able to say promptly and definitely what any particular fabric was made of was a triumph, not of pure chemistry, but of such mixed methods as Dr. Schlichter had explained. The value of these accurate methods of research to technical work was at present only dimly appreciated by those who had most to learn from them.

### A REVIEW OF THE METHODS OF PRODUCING OXYGEN COMMERCIALY.

BY E. T. THORNE, PH.D.

SOME time ago, when reading a paper before this Section on some industrial applications of oxygen (this Journal, 1889, 82—88) I promised a description of the process for producing oxygen on the industrial scale developed by the Brin's Oxygen Company. In redeeming my promise I think it may be of interest to our members if I preface this description with a brief sketch of the various methods which have been used or proposed for obtaining oxygen on the large scale.

(<sup>44</sup>) See *Musin*: Observations sur le Conditionnement Hygrométrique des Matières Textiles, 2<sup>e</sup> edit., 1877.

*Persoz*: Essai sur le Conditionnement, 1878.

*Storhay*: Renseignements Pratiques sur les Conditions Publiques, 1888.

(<sup>45</sup>) See *Grothe*. Technologie der Gespinnstfasern, p. 156. Zeitsch. d. Ver. d. Wollinteressenten, 1871.

The interest attaching to this problem from a practical point of view is shown by the fact that our Patent Office alone has, since 1849 (the date of the earliest patent I have found on this subject), granted no less than 53 patents for improvements in obtaining oxygen on what was intended by the patentees to be the commercial scale. I shall not, of course, attempt to notice all these specifications, many of which are manifestly absurd, contenting myself with referring briefly to the most important or remarkable ones; but at the end of my paper I give a complete list of the English patents on this subject.

The methods which have been employed for obtaining oxygen may be broadly classified under four heads:—

1. The decomposition by heat of compounds containing oxygen.
2. The decomposition by chemical means of compounds containing oxygen.
3. The decomposition by electrical means of compounds containing oxygen.
4. The extraction of oxygen from the atmosphere.

It would be going beyond the limits of this paper to review those methods which are only of theoretical or historical interest, and I shall therefore refer only to such processes as are of interest from a commercial or practical point of view.

1.—*Production of Oxygen by the Decomposition by Heat of Compounds containing Oxygen.*—The historically interesting method of preparing oxygen by the ignition of nitre—

by which Priestly first obtained oxygen in 1771, is also of interest from the point of view of this paper, as not only was it long one of the chief means employed for preparing oxygen in the laboratory, but was also the basis of many attempts to prepare this gas economically on the large scale. The first English oxygen patent recorded was taken out by S. White in 1849 (No. 12,536) for "Improvements in the manufacture of gases," wherein he proposed heating potassium or sodium nitrate in detached or moveable crucibles within retorts. Many subsequent patents were taken out (the last as late as 1865) for modifications of this process—nitrates or mixtures of nitrates with oxides or other non-fusible substances being employed. But the oxygen thus obtained is generally much contaminated with nitrogen and nitrogen oxides owing to the further decomposition of the nitrite when the heat is allowed to become too high, and no satisfactory results were obtained.

Priestly also described in 1779 the preparation of oxygen by heating manganese peroxide, when a third of the oxygen contained therein is evolved:— $3 \text{MnO}_2 = \text{Mn}_3\text{O}_4 + \text{O}_2$ . This peroxide occurring largely in nature as pyrolusite formed a cheap and convenient source for oxygen where considerable quantities were required, and its use has continued till the present day. But the high temperature needed has militated strongly against its general use.

But it is to Berthollet, who in 1785 first obtained oxygen by heating potassium chlorate above its fusing point, that we owe the method which until recently has probably been more used than any other. The heating of the pure chlorate is, however, attended with considerable danger, especially where large quantities are being used, as owing to decomposition commencing very little above the fusing point of the salt, and to the small amount of heat absorbed, or rendered latent, during the decomposition, the reaction when once it has started often becomes explosive in its violence, ruptures the containing vessel and scatters the molten chlorate. But the discovery that the admixture with the chlorate of small quantities of some non-fusible oxides (such as manganese peroxide, ferric oxide, &c.) causes the evolution of the oxygen to take place at a much lower temperature, far below the melting point of the chlorate, converted this into a very convenient means for producing oxygen. And the cheapening of the cost of potassium chlorate in late years rendered this so far an economical process that it almost superseded the rather more economical, but also much more cumbersome manganese peroxide method.

Another method which has found favour to some extent where considerable quantities of oxygen were required, is the decomposition of sulphuric acid by allowing it to drop on to red-hot surfaces. The acid is decomposed into sulphurous anhydride, water and oxygen—

and when oxygen alone is required, the water and anhydride are removed by passing the products of the reaction over suitable absorptive media. This method, however, has often been employed in the manufacture of sulphuric anhydride, when only the water has been removed by a desiccating agent, a mixture of sulphurous anhydride and oxygen in the proportions requisite for the formation of sulphuric anhydride being thus obtained. This process is probably cheaper than any of those just described, but the greater complexity in manipulation has made its use restricted mainly, I believe, to the manufacture of sulphuric anhydride. It forms the subject-matter of several patents, and is the process suggested by Squire in his patent for the manufacture of sulphuric anhydride (Eng. Pat. 3278, 1875) as the best for that purpose.

With regard to the relative cost of these methods it is difficult to speak with certainty, as authentic data are wanting. But even when prepared on the large scale, the cost per 1,000 cub. ft. will certainly, I believe, not be less than 8*l.*—10*l.* from chlorate, 4*l.*—6*l.* from pyrolusite, and 2*l.* 10*s.*—3*l.* from sulphuric acid, and probably, in the latter case, where deterioration of plant, &c. is taken into account, the cost will be much higher.

II.—*Production of Oxygen by the Decomposition by Chemical Means of Compounds containing Oxygen.*—In this class there are, as far as I know, no methods which have been employed on a really large scale, but there are several which are of interest to the practical man, where a small quantity of oxygen is required to be prepared without much trouble or expense, or where a slow but steady evolution of oxygen is required. Of these the oldest are the decomposition of peroxidised compounds, such as manganese dioxide, potassic bichromate, &c., by sulphuric acid. Taking these two as examples, the reactions are expressed by the equations—

A very steady stream of oxygen may be obtained by adding a small quantity of a cobalt or nickel salt to a concentrated solution of bleaching powder kept at a temperature of about 85° (Mitscherlich, 1843). The cobalt or nickel seems to act by being alternately oxidised to a higher and reduced to a lower state of oxidation, in this way acting as a carrier of oxygen, and liberating that contained in the bleaching powder. The reactions may be expressed by the equations—

Really only a modification of this method, and a modification hardly likely to find much practical application, is the process wherein a stream of chlorine is passed into hot milk of lime, whereto a little cobalt or nickel salt or oxide has been previously added. The proposal to obtain oxygen from water by passing a mixture of superheated steam and chlorine over very strongly heated surfaces was also too cumbersome and costly to find much practical use.

III.—*Production of Oxygen by the Electrolysis of Compounds containing Oxygen.*—In the preceding divisions we have been dealing with processes where a great part of the cost lies in the raw material which is destroyed in the process. We now come to a class where the cost of the raw material may be almost neglected, the expense lying in the means of obtaining the decomposition. For although the electrolysis of various other substances has been proposed, and even patented (*Gr.*, C. Watt, Eng. Pat. 13,755, 1851) for this purpose, we need only consider that of water as of practical importance. The first patent referring to

the use of the electrolysis of water for the production of oxygen is that of Madame Lefebvre (Eng. Pat. 1045, 1859), but, of course, the process had been known long before. The electrolysis of water has undoubtedly been used practically for the preparation of oxygen on the large scale, but the large and inevitable loss attending the conversion of heat into power and power into electrical force, and the need for skilled labour in working the electrical plant, must always militate very strongly against the economy of this method. It is difficult to obtain data of the actual cost of producing oxygen electrolytically, but in an elaborate and detailed specification of a recent patent (Eng. Pat. 15,935, 1888), the patentee, D. Latchinoff, estimates the cost of producing 23,000 ft. hydrogen (to be used for ballooning purposes) and 11,500 ft. oxygen at 36*l.*, and there is little doubt that the cost in practice would be found to be considerably higher.

IV.—*The Extraction of Oxygen from the Atmosphere.*—When Boussingault in 1851 made his important discovery that if barium oxide be exposed at or a little below a dull red-heat to a current of air it becomes converted into barium peroxide, and that this new compound is, at a somewhat higher temperature, reconverted into the monoxide with evolution of oxygen, he at once recognised the importance of this reaction as a means of extracting oxygen from the atmosphere, a problem which had long occupied the thoughts of chemists. That others also appreciated the value of Boussingault's discovery is evidenced by the fact that we find an English patent taken out in the following year (Eng. Pat. 390, 1852) by J. Swindells and W. Nicholson to utilise this reaction. Further patents on similar lines followed, and Boussingault and others devoted much work to the endeavour to bring the process to a successful practical issue. Large experimental works were erected in Glasgow, and much money spent thereon in a similar effort. But all these attempts failed to overcome the difficulty of the gradual loss by the barium oxide, after repeated oxidations and deoxidations, of its power of re-oxidation, and the reaction remained practically unavailable.

In 1865, J. T. A. Mallet took out a patent for extracting oxygen from the air by means of cuprous chloride. Cuprous chloride, when exposed to air, and especially to moist air, becomes converted into cupric oxychloride, and this, when heated to a dull red heat, yields up its oxygen, becoming reconverted into cuprous chloride, which may be again oxidised as before. The reoxidation may be partially effected in the retorts in which the oxychloride is heated, by passing air through them when partially cooled, and this reoxidation may be very much accelerated by the admission of a small jet of steam with the air current.

In 1866, Tessié du Motay and C. R. Marechal took out a patent for the extraction of oxygen from the air through the intermediation of alkaline manganates (Eng. Pat. 85, 1866). When an oxide of manganese is mixed with a strong base, and is subjected to the action of a current of air at a moderately high temperature, a manganate of the base is formed. If this manganate is then heated to a higher temperature and brought in contact with superheated steam, it is decomposed, oxygen is evolved, and a mixture of the alkali and manganese oxide re-formed. The reactions may be expressed by the following equations, though of course the actual mixtures re-formed will vary according to the quantity of steam and the temperature employed—

The mixture was said to undergo no deterioration (though this was not found to be the case in practice), and the process seemed thus a continuous one of great promise. Companies were formed and works erected at Paris, Lille, Brussels, Vienna, and New York. For a time some of the streets of Paris were lighted by oxyhydrogen lights, a double system of piping being laid down for the purpose, and the New York Company undertook and carried out the lighting of the work during the building of Brooklyn Bridge. It is difficult to obtain authentic information of the cost of

oxygen as produced by these companies, but it appears to have been about 3*l.* to 4*l.* per 1,000 cub. ft. In the Journal of the German Chemical Society (Ber. 1870, 901) there is a glowing account of the then state of the New York Company, which was said to be producing 3,000 cub. ft. per day, some of which at least it was selling at the handsome price of 18*s.* for 60 gallons, or 1*s.* 10*d.* per cub. ft. A curious commentary, however, on the flourishing state of the company is the fact that it failed in 1871, and all the other companies formed for working these patents seem to have suffered a similar fate.

Probably both this and the cuprous chloride methods produced oxygen, when prepared in very large quantities, at a far lower cost than that of any of those previously described, and their failure was most likely largely due to the cost still being too high for the application of oxygen to industrial pursuits and to the quantity required for retail trade capable of standing the high cost, being too small to make such large works profitable.

The same may probably be said for the next process of extracting oxygen from the air by taking advantage of the varying solubility of oxygen and nitrogen in water or other solvents, for which a patent was taken out by Mallet in 1869 (Eng. Pat. 2137, 1869). Taking water as the most suitable solvent, the coefficient of solubility of oxygen is .046, that of nitrogen .025. The air was compressed over water, the excess of nitrogen allowed to escape, and the dissolved gases extracted from the water by the help of a vacuum pump. In this way a mixture containing 33.3 per cent. of oxygen was obtained, and if this mixture was subjected to a repetition of the treatment the percentage of oxygen was increased. After four treatments, a mixture containing 75 per cent. of oxygen was said to be obtained, and after eight treatments oxygen of 97.3 per cent. purity resulted. This process seems to have been adopted by Phillips in his experimental lighting of part of Cologne about 1871-72 by special oxygen-fed oil lamps.

Attempts have been made to utilise the law of diffusion of gases, and of the fact established by Graham that caoutchouc membranes allow the passage of oxygen more readily than that of nitrogen, but hitherto with no practical success, and these phenomena do not seem likely to lend themselves to the production of oxygen on the large scale.

It was thus that the matter stood when, in 1880, the MM. Brin, frères, took out their patent (Eng. Pat. 1416, 1880), in which they claimed to have overcome the deterioration of the baryta, which had hitherto been the stumbling-block to the realisation of Boussingault's expectations. The permanency of the baryta was attained by a combination of great care in the preparation of the baryta in a suitable physical condition, of the careful purification of the air, and of the employment of reduced pressure during deoxygenation, by which means a lower temperature suffices for such deoxygenation. Further improvements were patented by the MM. Brin in 1885. The specially prepared baryta was heated in horizontal steel tubes or retorts to a dull red heat (about 600°) and a current of air, carefully dried and purified, forced over it under a pressure of about 10 lb. on the square inch. When the oxidation was completed, or carried as far as was found practically desirable, the pumps were stopped and the temperature of the retorts raised to a full red heat (about 850°) and connected with the pumps working as vacuum pumps. The previously absorbed oxygen was then evolved and passed from the pumps into the gas-holder. The process was thus made workable and continuous, but practical working still showed defects, and the cost of the oxygen obtained still remained too high for its application to industrial purposes. One of the difficulties lay in the formation of channels above the baryta owing to the subsidence of the latter; another, the difficulty of keeping the joints of the connecting pipes perfectly tight, owing to the irregular expansion of the retorts horizontally embedded in a brick furnace. Both of these difficulties were overcome by the adoption of vertical retorts. These are supported at the upper end, the lower end passing loosely through asbestos packing, and so allowing all expansion and contraction to take place freely. All the pipes connecting with the pumps, &c. are fixed to the upper ends of the retorts, and are thus not

affected by the expansion or contraction of the retorts. But the greatest defect in this process, when considered as one to be put in the hands of manufacturers, was the great changes of temperature required. Not only did these changes increase very markedly the wear and tear of the plant, but they caused such a great waste of time whilst they were being effected, that whereas what we may term the *active* or pumping period of an operation occupied from an hour and a half to two hours, the whole operation could not be effected much under four hours.

It has long been known that where a solid and a gas combine to form a solid, increase of pressure aids such combination, and conversely that when a solid decomposes into a solid and a gas, reduction of pressure aids such decomposition. It was hardly anticipated, however, that this effect of change of pressure would be sufficient to remove the need of change of temperature in a reaction such as that under discussion, but experiment showed that such was the case. It was found that if the temperature of the baryta was maintained at about 700° (or a little below the mean of the temperature previously used), a current of air under a pressure of about 10 lb. on the square inch above atmospheric caused considerable peroxidation, and that when the air current was stopped and the pressure reduced to about 13-14 lb. below atmospheric a considerable evolution of oxygen and deoxygenation of the peroxide occurred. Theoretically 1 lb. of baryta should absorb during peroxidation 1.25 cub. ft. of barium, and of course this same amount should be evolved on subsequent deoxygenation. In practice, where two temperatures were employed, about half the theoretical amount was obtained per operation. When a constant temperature of about 700° is maintained about .1 cub. ft. per operation is the result. But whilst an operation under the old conditions occupied about four hours, an operation under the constant temperature method can be completed in from 10 to 15 minutes. So that although the yield per operation under the new conditions is much smaller than heretofore, the yield per day is much larger. The maintenance of one temperature effects, of course, a considerable economy in fuel and wear and tear, and what is perhaps more important still from a practical point of view, it economises both in the quantity and quality of labour required. The multiplied reversals of pumps, cocks, &c. required by the new method is effected automatically by reversing gear designed by K. S. Murray, so that the labour required is reduced to that needed for stoking the furnaces and oiling and supervising the pumps.

For the barium oxide, the main desiderata are porosity and hardness. These are found to be best obtained by preparing the oxide from the nitrate. The nitrate is gradually filled into fireclay crucibles already heated in a coke fire to about 880°. The nitrate rapidly fuses, and decomposition soon commences, with evolution of oxygen and oxides of nitrogen. This decomposition continues for about three hours, during which time the contents of the crucible remain in violent ebullition, owing to the evolved gases. A porous mass is thus left, which is ignited for another hour to complete, as far as possible, the decomposition. In this way a very porous, but also hard baryta is obtained, the yield being about half the nitrate taken. The cost of the baryta is about 7*s.* per cwt. This is higher than the quoted price of many manufacturers, but hitherto samples that have been obtained elsewhere have failed to combine the requisite hardness and porosity.

The purification of the air is an important item in the success of the process, and this is effected by passing it through one or more drying chambers filled with quicklime, and finally through one containing lumps of caustic soda. In this way almost the whole of the carbonic anhydride and moisture is removed, the main work being done by the lime, the soda really acting as a catch purifier. Taking 1.25 per cent. by volume as a very rough average of the moisture present in the atmosphere in Great Britain (and this is certainly above rather than below the actual figure), one ton of lime should purify 3,000,000 cubic feet of air from moisture and carbonic anhydride, and in practice about 70-80 per cent. of this efficiency is attainable. Very little soda is used up, and both the spent lime and spent soda are

Fig. 3.

Fig. 1.

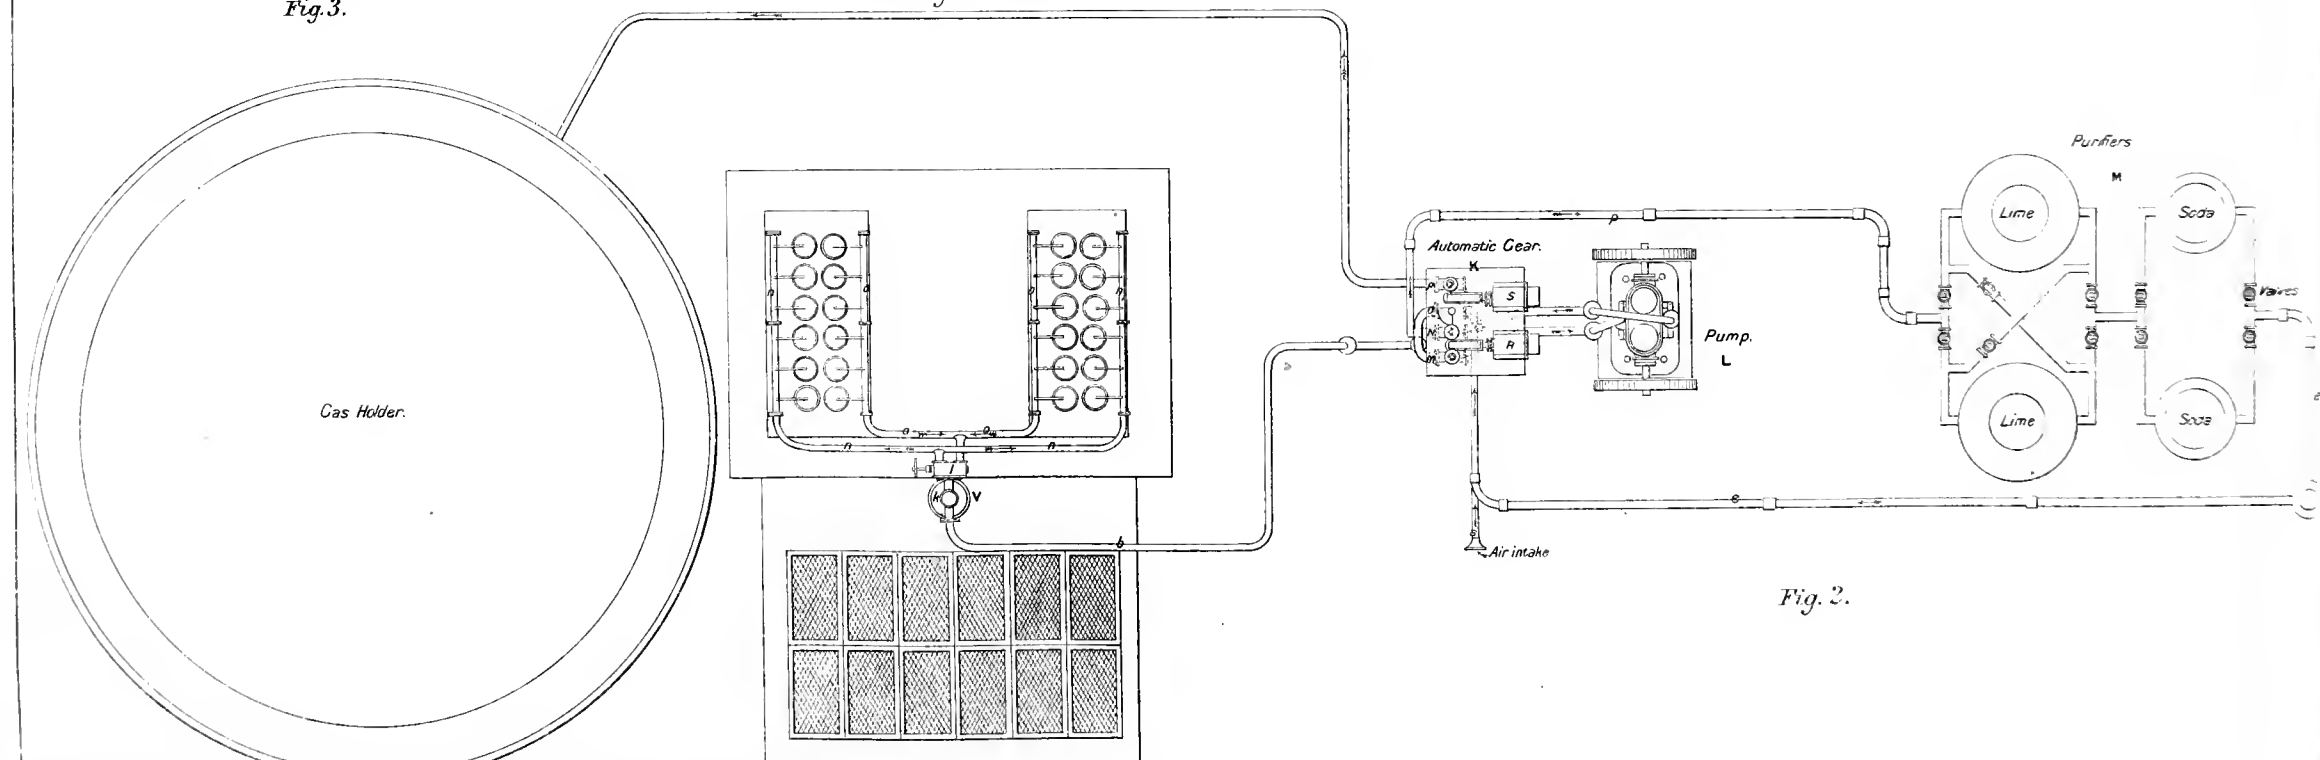

Fig. 2.

Fig. 1.

Fig. 2.

Fig. 3.

saleable, so that even their prime cost, which is small, is further reduced.

With regard to the purification of the air, there is a point of interest to which I would briefly refer. Of course, the purification of the air on a large scale cannot practically be made as perfect as on the small scale. Boussingault purified his air very thoroughly, and found the baryta gradually lose its absorptive power for oxygen. The admission of steam to the baryta restored its absorptive power, but at the same time had a deleterious effect, by causing disintegration. Now, all my experience in connexion with this process tends to confirm my belief that the trace of moisture left in practice in the air aids in keeping the surface of the baryta in a good physical condition, without being sufficient to cause disintegration. And though to the causes mentioned earlier in this paper the success of the process is largely due, I believe that the almost inevitable imperfection of an industrial process plays, in this one case, a not altogether negligible rôle in its success.

A detailed description of the plant used in this process is given by K. S. Murray, in a paper "On the Mechanical Appliances employed in the Manufacture and Storage of Oxygen" (Proc. Inst. Mech. E. Jan. 1890), and it is, therefore, unnecessary to repeat it here. The accompanying diagrams will, however, help to make the process clear. Fig. 1 shows the arrangement of purifiers, pumps, and producer, the latter being given in section parallel to its front. Fig. 3 shows a section of the producer taken at right angles to the front, through the centre of the carbonic oxide generator and combustion chamber. Fig. 2 shows a plan of the whole plant.

The carbonic oxide is generated in A (Figs. 2 and 3), which is fed with coke through D, the primary air-supply entering by restricted openings at E (Fig. 3). The carbonic oxide thus generated passes through the opening at the top of chamber A into the combustion chamber B (Figs. 2 and 3), being met at its entrance by the secondary air-supply, which, being admitted by the opening shown some little distance above E, has been heated by passing through the hot walls of the furnace, as shown by the channels marked "air." Complete combustion takes place in the combustion chamber B, and the hot products of combustion then pass by the outlet holes shown in plan in Fig. 3 and in section at G, Fig. 2, into the heating chambers C (Fig. 2) (placed on each side of the combustion chamber), in which the retorts are hung, finally passing away at the bottom to the chimney.

When the process is in operation, air is drawn in by the "air intake" (Fig. 2) through cock *m* by the pump L, by which it is forced, under a pressure of 10 lb. per square inch, through cock N, to the purifiers M. These are so

arranged that either one or both lime purifiers and one soda purifier are in action. The air then passes again through the automatic gear by the two-way cock O to pipe *b*, which takes it to the distributing valves V and I at the top of the furnace. Thence it passes, by pipes N, to the outside row of retorts in each heating chamber, through which it passes downwards, and thence by the connecting pipes shown in Fig. 2 upwards through the inner rows of the retorts, the impoverished air finally escaping by a relief valve on V. Provision is made in the distributing valves V and I whereby the direction of the air current may be altered from time to time, so as sometimes to pass downwards through the inner rows of retorts and upwards through the outer. When the oxidation has been carried on for the suitable time the automatic reversing gear shifts over the cocks, the purifiers being thus cut off under pressure. The exhaust cylinders of the pump being thus brought into direct communication with the retorts through the distributing box, soon cause a reduction of pressure therein, whereby the relief valve is automatically closed, and the pipes *n* and *o* both brought into communication with pipe *b*. As soon as the reduction of pressure in the retorts reaches about 26—28 in. mercury (13—14 lb. per square inch) below atmospheric the barium peroxide begins to give off its oxygen. This is then drawn to the pump, which delivers it into the holder. The first portions of oxygen so drawn into the pump still containing much nitrogen, the automatic gear is arranged not to open the cock to the holder till some few seconds after the reversing of the other cocks, the mixed oxygen and nitrogen meanwhile escaping by a snifting-valve opened by the gear for the purpose.

As now arranged the plant is one that can be readily erected in works where large quantities of oxygen are required, and needs no further skilled supervision than is always available in such works. For a producer capable of producing 10,000 ft. of oxygen per 24 hours the consumption of coke in the furnace is about 12—15 cwt., and for plant of that or smaller size the pump-power required is about 1 I.H.P. per 1,000 ft. of oxygen produced per day, the ratio decreasing for larger plants. The cost of oxygen making must always vary according to circumstances, but will be very small. Allowing for interest on plant, depreciation, &c., the cost into the holder will range from about 7s. per 1,000 cubic ft. in works specially erected for oxygen production, to 2s. per 1,000 in large works where fuel is low, and power and labour will entail little extra expense. This cost brings oxygen within the range of practical application for industrial purposes. Already numerous applications are in practice or prospect, and manufacturers are now turning their attention to the subject, so that doubtless many more will very soon be found.

## APPENDIX.

### ENGLISH PATENTS TAKEN OUT FOR THE OBTAINING OF OXYGEN.

Year.	No. of Patent.	Patentees.	Short Title of Patent.	Method Proposed for Obtaining Oxygen.
1849	12,536	S. White.....	Improvements in the manufacture of gases, and in the applications thereof, &c.	Heating potassium or sodium nitrates in detached or moveable crucibles within retorts.
1851	13,755	C. Watt.....	Improvements in the decomposition of saline and other substances, and in separating their component parts or some of them from each other, &c.	The electrolysis of saline nitrates and sulphates.
1852	390	J. Swindells and W. Nicholson.	Improvements in obtaining oxygen gas and applying it in the manufacture of various acids and chlorine, &c.	Heating barium oxide, alone or mixed with infusible oxides, in a current of air at a dull red heat, and decomposing the peroxide formed by a current of steam at a higher temperature.
1853	998	G. K. Geyelin .....	Improvements in the manufacture of white oxide of zinc.	Heating barium peroxide or manganese peroxide.
1859	1045	Mdme. Lefebvre (Agent, W. E. Newton.)	Improvements in the manufacture of nitric acid and its application for the production of artificial nitrous or nitric salts.	"Decomposition of atmospheric air by means of dynamic and static electricity."

ENGLISH PATENTS TAKEN OUT FOR THE OBTAINING OF OXYGEN—*continued*.

Year.	No. of Patent.	Patentees.	Short Title of Patent.	Method Proposed for Obtaining Oxygen.
1860	1380	G. Bower.....	Improvements in apparatus for manufacturing, controlling and regulating the flow of gas.	Heating manganese peroxide in special retorts.
1860	1563	C. Binks (provisional only).	Improvements in manufacturing oxygen gas.	The decomposition of steam by chlorine at high temperatures, and absorption of the hydrochloric acid formed.
1860	2132	H. J. Standley (provisional only).	Improvements in the production of gas for illuminating and other purposes, &c.	From nitrates and other compounds of sodium, potassium, &c.
1860	2711	J. Webster (provisional only).	Improvements in obtaining gas (mainly oxygen) for improving artificial light, and for other purposes, &c.	By heating potassium nitrate or other nitrate to a bright red heat in iron retorts.
1860	3179	C. Binks.....	Improvements in manufacturing certain gases applicable in generating heat and light and in bleaching.	Similar to 1563/60.
1861	932	J. D. Malcolm (provisional only).	Improvements in the manufacture of nitric acid and caustic soda which are also applicable to the obtaining of other chemical products.	Heating sodium nitrate with sand, &c.
1861	983	J. Webster (provisional only).	Improvements in manufacturing oxygen gas, and obtaining certain other products.	Heating alkaline nitrates with iron oxide.
1861	2607	J. Webster .....	Improvements in manufacturing oxygen gas, and obtaining certain other products.	Similar to 983/61.
1862	1496	C. Binks .....	Improved methods of obtaining oxygen and chlorine gases.	Similar to 1563 60.
1862	2265	J. Dickson (provisional only).	Improvements in the manufacture of chlorine for commercial purposes.	Electrolysis of saline solutions.
1862	2556	L. Mond (provisional only).	An improved method of obtaining hyponitric acid and nitric acid from nitrate of soda.	Heating sodium nitrate with infusible and indifferent oxides, &c.
1862	3085	C. Binks (provisional only).	Improved methods of obtaining oxygen and chlorine gas.	Similar to 1563 60.
1865	5	J. F. Parker and J. Tanner.	Improvements in the manufacture of oxygen gas, &c.	Heating a mixture of sodium nitrate and quicklime.
1865	1833	C. Tellier (provisional only). (Agent, H. A. Dufrené.)	An improved process for obtaining oxygen ...	Passing a mixture of chlorine and steam through a red-hot tube.
1865	2634	J. T. A. Mallet.....	A new or improved process for the manufacture of oxygen.	The alternate oxidation of cuprous chloride by means of air or air and steam to cupric oxychloride, and decomposition by heat of the oxychloride, with consequent evolution of oxygen.
1866	85	C. R. Marchal and C. M. Tessié du Motay. (Agent, R. A. Brooman.)	An improved method of producing oxygen ...	Alternate formation of manganates, chromates, &c. by heating mixtures of alkalis and oxides of manganese, chromium, &c. in a current of air, and decomposition of these manganates, &c. by a current of steam.
1866	3171	J. T. A. Mallet.....	A process and apparatus for producing jointly or separately oxygen and chlorine from the same chemical substance and in the same apparatus.	Mainly special plant for 2934 65, and adding an inert material to the active agents to prevent fusion, &c.
1867	568	H. A. Achereau. (Agent, W. Clark.)	Producing and applying oxygen .....	Decomposition of sulphuric acid by heat.
1867	1040	C. M. Tessié du Motay, and C. R. Marchal, (Agent, C. S. Brooman.)	Producing oxygen .....	Acting on sulphuric acid with oxides of iron, zinc, aluminium, or with silicate of aluminium.
1868	2352	J. Lewis (provisional only).	Combustion of fuel .....	Passing current of steam over any heated oxygenous compound.
1869	291	W. Weldon (provisional only).	Manufacture of chlorine and oxygen .....	Heating or treating with sulphuric acid Weldon mud.
1869	2137	J. T. A. Mallet .....	Charging atmospheric air with oxygen.....	Utilising greater solvent power of water for oxygen than for nitrogen. Air is subjected repeatedly to action of water under pressure.
1870	498	P. Broechi (Agent, J. H. Johnson) (provisional only).	Obtaining oxygen gas .....	Similar to 2137 69 but also using alcohol, glycerin, &c. in place of water.
1870	1300	E. T. Kirkpatrick.....	Producing oxygen gas .....	Adding a small quantity of a cobalt or nickel oxide or salt to a hot solution of bleaching powder.
1872	3261	J. A. Wanklyn.....	Production of oxygen gas .....	Heating a mixture of cupric oxide and barium oxide alternately in current of air and of steam.

ENGLISH PATENTS TAKEN OUT FOR THE OBTAINING OF OXYGEN—*continued.*

Year.	No. of Patent.	Patentees.	Short Title of Patent.	Method Proposed for Obtaining Oxygen.
1873	435	C. W. Harrison (provisional only).	Treating air for manufacture of gas.....	Treating air with water, or other liquid capable of dissolving more oxygen than nitrogen, under pressure.
1873	528	C. W. Harrison .....	Obtaining oxygen gas .....	Passing air into magnetised iron vessels either containing water or not. The nitrogen passes on the oxygen is retained.
1876	5907	C. Hornbostel. (Agent, W. Morgan-Brown.)	Preparing and applying oxygenated air for combustion.	Enriching air by pumping it through a paste of manganese peroxide and strong sulphuric acid, when oxygen is liberated which combines with the air.
1879	3302	P. Aube .....	Manufacture of lighting and heating gas .....	Absorption of air by water under pressure; or from manganates, &c.
1878	5123	G. E. Dering.....	Improved means of obtaining light, heat, and motive power.	Electrolysis of water.
1879	4127	A. Brin, A. Valière, and L. Q. Brin.	Producing of light and heat .....	Passing sulphuric acid into strongly heated retorts containing siliceous matter.
1879	4650	J. Rochford (provisional only).	Generation and application of oxygen and hydrogen gases for combustion in boiler furnaces.	Steam through heated earthenware or terracotta pipes, when oxygen alone is evolved (!)
1880	1416	L. Q. Brin and A. Brin. (Agent, P. Jensen.)	Production of oxygen and nitrogen gas.....	By alternately heating barium oxide in a current of air to form barium peroxide, and heating the peroxide alone, whereby oxygen is evolved and barium oxide reformed; increase and reduction of pressure being used as accessories.
1881	781	E. B. Reynolds (Agent, H. J. L. Haddan.)	Extracting oxygen from the atmosphere .....	Passing air through fibrous material soaked in naphtha, petroleum, or other fit product and broken charcoal, whereby the nitrogen is absorbed (!).
1881	1897	W. A. Barlow.....	Obtaining, &c. gas for lighting and other purposes.	Electrolysis of water. <i>Part</i> of the oxygen and hydrogen so produced is used to drive the dynamo. (Perpetual motion !)
1881	2080	N. A. Hélonis (Agent, A. M. Clark.)	Apparatus for making oxygen and hydrogen .	Heating a mixture of silica and plaster of Paris, when oxygen is evolved. Or dialysis of air through india-rubber septa. Or repeated absorption of air under pressure by water, alcohol, glycerin, &c.
1882	2875	R. J. Gülicher.....	Gas batteries and apparatus for producing hydrogen and oxygen by electricity.	Electrolysis of water.
1884	8285	A. Stamm (Agent, G. F. Redfern.)	An improved apparatus for preparing oxygenated air.	Elaborate apparatus for obtaining, by Mallet's principle of absorption of air by water, glycerin, &c., a constant stream of oxygen.
1884	15,026	A. and L. Q. Brin (provisional only).	Separating and obtaining oxygen and nitrogen from atmospheric air.	—*—
1885	157	A. and L. Q. Brin .....	Improvements in the separation and obtaining of oxygen and nitrogen from atmospheric air.	Improvements connected with 1416/81.
1887	7268	Hommel (provisional only).	Obtaining oxygen .....	—*—
1887	16,987	E. B. Ellice-Clark and L. Chapman.	Improvements in apparatus for the production of oxygen and nitrogen gases from atmospheric air.	Apparatus connected with carrying out patents 1416/81 and 157/85.
1888	1844	E. B. Ellice-Clark and L. Chapman.	Improvements in and apparatus for or connected with the production of oxygen and nitrogen gases from atmospheric air.	Apparatus and improvements connected with patents 1416/81 and 157/85.
1888	3880	E. B. Ellice-Clark and L. Chapman.	Improvements in apparatus for the extraction of oxygen and nitrogen from atmospheric air.	Improvements on and apparatus for patents 1416/81 and 157/85.
1888	3967	A. Brin .....	An apparatus for the extraction of oxygen and nitrogen from atmospheric air.	Improved apparatus for patents 1416/81 and 157/85.
1888	15,935	D. Latchinoff .....	Improvements in the production of oxygen and hydrogen in large quantities.	Electrolysis of water.
1889	11,899	C. Huelser (Agent, G. Kassner.)	A process for preparing plumbates of calcium, barium, and strontium, and for employing the same for oxidising purposes and for producing oxygen and other bodies.	Preparation of plumbates by heating mixtures of lead oxides and alkalis in a current of air, and subsequent decomposition of the plumbates by steam, or use in various ways as oxidising agents.
1889	13,712	R. D. Bowman (provisional).	Improved process for the production of oxygen gas.	Not yet completed.

\* Since 1884 the contents of a provisional specification are not made public unless the patent is completed.

## DISCUSSION.

The CHAIRMAN said that possibly from a purely scientific point of view the process of manufacturing oxygen which Dr. Thorne had just described was not more interesting than the most ancient of all such methods, which in one respect—the alternate reversal of operations—it somewhat resembled. He referred to the method for producing oxygen by the alternate oxidation and deoxidation of quicksilver by the slightly increased or diminished heat. But those who had ever tried the latter would appreciate the vast difference, from an economic point of view, between a process giving oxygen at a cost which he would not venture to calculate, and one yielding it at such a price as made it of economic value. The whole secret of the application of scientific truth to practical life turned on the question of *2 s. d.* It was not sufficient to have a perfect scientific or engineering process. What was essential was that the process should be workable at such a price as would give a profit on its practical application. Here was a process which was not alone in this respect—many other valuable and most important processes being in the same position—namely, that it was for a long time unworkable owing to difficulties of application rather than difficulties of theory. Those of the members who were acquainted with the earlier days of the process for the manufacture of oxygen from baryta would well remember the utter disappointment which followed the first trials; and it was additionally interesting therefore to find that the study of a series of minute details had led to results which were so highly satisfactory and encouraging.

Dr. SQUIRE said that he remembered seeing at Pantin, near Paris, many years ago, the process for producing oxygen patented by Du Mothay. Very sanguine views were expressed about it at the time; but, as Dr. Thorne had said, it did not succeed, because the whole thing sintered together into a mass in the retorts, so that there was practically no surface left for the absorption of oxygen. What, he fancied, had to a certain extent interfered with the prosecution of experiments in the manufacture of oxygen was the fact that in the present condition of metallurgy there scarcely seemed to be much use for it. The use of regenerative furnaces overcame any difficulty that there might be in the heating up of the nitrogen; so that when the air, which passed over the regenerators before it entered the furnace, came into the heart of the combustion chamber, the nitrogen in it could do no practical harm. A temperature could be got equal to the temperature of the dissociation of the compounds formed by combustion, and capable of melting down the furnaces. He did not know what more they would wish than that. The application of oxygen in large industrial operations seemed to be very limited. There were certain small metallurgical operations, however, such as the fusion of platinum, and there was the possibility of employing oxygen in the coal gas industry mixed with the gas, or for the regeneration of the oxide, though for that purpose air would practically do as well. Then there was the lime-light on the stages of theatres and for use in magic lanterns. Beyond these he did not see what was to be done with the oxygen when it was obtained. Much skill had been bestowed upon the apparatus, and it was very ingenious. Perhaps some of the automatic action might have been achieved in a simpler way; but apart from that it seemed to be well constructed. He repeated, however, that there appeared to him to be very little future for the oxygen manufacture.

Mr. B. E. R. NEWLANDS entirely agreed with Dr. Squire. He had seen the Brin process several times, and each time had heard of some new application of oxygen looming in the future. Some years ago it was to be a grand thing for purifying sugar. He sent a sample of syrup to be treated, and it certainly came back with a much better colour; but the density of the solution was so much reduced that he had no difficulty in ascertaining the reason for the colour improvement. He was told that the effect of the oxygen was to polarise the liquid in some way; that the ash in the sugar consisted of animalenka, and that on passing a current of ozonised oxygen through it, they marched out like a regiment of soldiers. He was

glad to see that the company now had the assistance of a gentleman of whom they all had a high opinion. That would put the affair on a scientific basis, which was greatly needed. On his last visit to the works he was told by a gentleman that the cost of producing the oxygen was 9s. per 1,000 ft.; another put the cost at 5s., and later on in the day the inventor of the process informed him that it could be made for 10d. Now, the cost of production was put at about 2s. 6d. per 1,000 ft. But of what use was oxygen at 2s. 6d. when it could be got in the air for nothing, and when one had merely to compress the air to get the same effect practically in most cases as with pure oxygen? He agreed with Dr. Squire that the only real use for oxygen at present was in the revivification of oxide of iron in gas making; but that operation could be done almost as advantageously by air. He felt grateful to Dr. Thorne for the interesting account he had given, but did not think the subject was of much practical importance at present. Perhaps, however, Dr. Thorne's work would be the means of opening up new uses for oxygen in the future.

Dr. THORNE in reply said that he had carefully refrained from going into the question of the applications of oxygen, because such an addition to his paper would have carried him too far. He had already, in a former paper, referred to several applications which he believed would come to be of great practical importance; and he hoped before long to be able to bring before the Society further information relating to the use of oxygen in other ways. It was easy to say that one did not see the need for oxygen, and that air would do as well. The English being a very conservative nation, it was not unusual to say of a new thing that it could not possibly succeed. Probably most of the members had heard of the famous lecture given by Dr. Lardner, wherein he proved to absolute conclusion that it was impossible to cross the Atlantic in a steamer, because, amongst other things, no vessel could carry sufficient coal for the voyage. At the conclusion of the learned doctor's argument, somebody at the top of the room was heard to laugh, whereat the doctor turned indignantly upon him to ask the cause of his mirth, and received the reply: "I beg your pardon, but I could not help it, for I have just landed from the first steamer that *has* crossed." When the question of oxygen production was introduced a few years ago in connexion with the Brin process, the company was met with similar arguments. It was said that it was impossible that baryta should retain its power of absorbing the oxygen; and learned members of the Society he was addressing, and of the Royal Society, were heard to state openly that they did not believe in the possibility, and that the oxygen produced by day must have been produced by fresh baryta brought in every night. The company had, however, been going on for three or four years, and last year they had sold by retail about a million cubic feet of oxygen. It was hardly necessary to say that they could not have gone on selling at that rate if they had had to import baryta into the works every night and put it into the retorts. They had in hand many chemical reactions, and were noticing the effect of mass in determining them. That, he thought, was one of the points too much overlooked when it was said that it was impossible to have large applications for oxygen. He would mention, though he had not intended to do so, that he had been making experiments on the thickening and oxidation of oils, and had succeeded in getting results with oxygen which had not been obtainable with air. The large amount of nitrogen which had to be pumped through the oil if it was to be oxidised by atmospheric oxygen interfered greatly with the result of the reaction. He fully believed that the oxidation of oils would in time become a very important outlet for oxygen. There were many other applications which he might speak of, but which he would prefer to leave over till a later date, when the experiments relating to them should have been more fully worked out than at present. He might mention, however, that over and above seven furnaces now erected and more or less closely connected with the company, they were putting up furnaces at two chemical works (one in Germany, the other in England) for use in applications worked out quite independently.

From Germany they were getting a great many inquiries with regard to the use of oxygen for the manufacture of sulphuric anhydride on the large scale, which he was convinced would be an important application of oxygen; and there were a number of others in view, and doubtless many more which had not yet occurred to them, but which might become large outlets for oxygen now that it was to be got at a price which would enable manufacturers to use it on a large scale. At the cost he had mentioned—varying from 3*l.* to 10*l.* per ton—oxygen would replace a great many other reagents that were being used at present. There was one application to which he had referred before, but which he would mention again in reply to the suggestion that air was as good as oxygen in almost all chemical reactions. He referred to the use of oxygen for bleaching paper pulp. He had proved, conclusively he thought, and on the large scale, that when oxygen was used in conjunction with bleaching-powder, a very large proportion of the latter might be replaced by a small portion of the former. In working on a ton of grass used for papermaking, which would require about 2 cwt. of bleaching-powder in the ordinary way, by using about 200 ft. of oxygen the bleaching-powder required would be reduced to about 1½ cwt. He had made careful experiments on the effect of using air in conjunction with bleaching-powder, and had found that, working in the laboratory on a scale of a quarter cwt. of material, air did not at all diminish the quantity of bleaching-powder required, whereas the use of oxygen in similar experiments reduced it in many cases by nearly 50 per cent. The difference was mainly due to the fact that, at the moment of reaction, chlorine and nascent oxygen were liberated, and the large amount of nitrogen passing through carried away some of this chlorine and oxygen before it had time to act. That showed that in many cases where one did not expect oxygen to be valuable it was so, for, he confessed, that when he entered on the bleaching experiments he did not expect a very beneficial effect. In conclusion, he could only say that, personally, judging from experience, he felt decidedly sanguine that there were large—very large—applications for oxygen, and that in the course of a few years it would be found to be playing a very important part in chemical manufactures.

## ESTIMATION OF ALUMINA BY TITRATION.

BY C. F. CROSS AND E. J. BEVAN.

In the current issue of the Bull. Soc. Ind. de Rouen (17, 402) there is an account of a paper by ourselves on "The Economy of Pure Caustic Soda" which appeared in this Journal (30 April, 1889). In the course of the investigations forming the subject of that communication, we obtained results showing that alumina in solution as alkaline aluminate could be estimated by titration in presence of methyl orange, the colour change taking place in the case of sulphuric acid at a point corresponding with the formation of a sulphate,  $2\text{Al}_2\text{O}_3 \cdot 5\text{SO}_3$ . It is noted in the transcript of our paper that in this observation we have been anticipated by M. J. Baeyer in a paper published in the *Moniteur Scientifique* (1886, 1133), and reappearing in a paper by M. E. Blondel in the Bull. Rouen 1887, 205. We take this earliest opportunity of acknowledging the priority of Baeyer's researches, the publication of which we had altogether overlooked.

Mr. P. BRAHAM exhibited an improved pinch-cock for regulating the flow of liquids, as from burettes, or gases in elastic tubes.

One form of the pinch-cock consists of two plates of suitable material—metal, vulcanite, xylonite, &c.—having

V-shaped slots (Fig. 1) and small clips *a*, turned over so as to retain the reverse slotted plate in position (Figs. 1 and 2, *a, a*). The plates have thumb-plates at right-angles thereto, for convenience in compression (Fig. 2, *b*). The pinch-cock, ready for use, is shown in Fig. 3. In action the slots

Fig. 1.

Plan of one Slide.

Fig. 2.

View of end showing Thumb Plates.

Fig. 3.

Plan of both Slides in position.

gradually overlap, and as their apices approximate, compression of the flexible tube takes place. The advantages appear to be the ease with which the pinch-cock can be removed without disturbance, and the manipulation with one hand while the other hand is left free to agitate or stir flasks or beakers, and for other necessary manipulation.

Another form of pinch-cock, in which the constricted-slot principle is effected by the compression of thumb-

Fig. A.

Fig. B.

Fig. C.

Pinch-cock showing Curved Slots.

pieces, diminishing the size of the slot by rotary motions of the plates from a common centre. (See Figs. A, B, C).

The principle is adapted for pinch-cocks on a large and even technical scale.

MESSRS. CROSS AND BEVAN exhibited a set of electrical apparatus made by Mr. Hume, of Edinburgh, useful for demonstrations. The interest of the exhibit was its unusual cheapness.

Mr. THOS. CHRISTY exhibited a Bunsen burner with a device attached, in the form of a bow of platinum wire over the orifice of the burner, which prevented "backwardation" of the flame.

DR. F. HURTER IN THE CHAIR.

## SULPHATE OF LIME IN CEMENT AND A DIRECT PROCESS OF CALCINATION.

BY J. S. RIGBY, F.C.S.

THE recovery of sulphur from vat waste by the Chance process having now assumed the form of a settled industry, manufacturers of that product will naturally look forward with interest to any advantageous arrangement for the

disposal of the residual impure carbonate of lime, which contains amongst its impurities a small percentage both of free and combined sulphur, which many people have thought would prove an insuperable obstacle in the production of a good reliable Portland cement.

As it is now over a year and a half since I made several tons of cement from the Chance waste, and as samples, such as briquettes and sample pats, placed on the walls of buildings fully exposed to the weather, have continued to improve in quality, it may be fairly said to have stood the test of time. The briquettes showed an increase on the tensile strain of 220 lb. on the 1 in. sectional area, the average breaking strain of the fresh cement on the usual seven days' test was 430 lb., whilst two briquettes 18 months afterwards tested as follows:—

No. 1.....	710 lb. on the square inch.
No. 2.....	590 lb. on the square inch.

giving an average of 650 lb. on the 1 in. sectional area, or an increase in tensile strength of 220 lb. as mentioned.

The bulk of the cement manufactured from the waste was quite equal in quality to the samples.

In bringing under your notice the manufacture of cement from Chance waste, it is for the purpose of showing that calcic sulphate existing in cement in small quantities does not to any appreciable extent interfere with the test of time. It will be noticed that the tensile strain exerted in the fresh cement was rather low; this I attribute to the rather excessive amount of the sulphur salt, owing to my not having at the time a good form of apparatus for purifying the waste (in quantity). The cement produced therefrom contained 2·85 per cent. of calcic sulphate, or 1·05 per cent. more than the average of three samples of London cement, which gave 1·80 per cent.

I find that the setting properties of cement can be restrained to almost an unlimited extent by the addition of plaster of Paris. Consequently the existence of calcic sulphate as an impurity in cement interferes with its testing properties very materially.

The following tests are made from cements produced from four distinct kinds of waste lime material, all of which contain calcic sulphate (naturally) in various proportions. For comparison I also include the test of a sample of London cement.

	London.	Caustic Lime Mud.	Chance Mud.	Solvay Mud.	Mud from Sugar Works.
CaSO <sub>4</sub> .....	1·80	2·20	2·85	1·60	3·60
	Lb.	Lb.	Lb.	Lb.	Lb.
Tensile strain on the square inch in seven days	480	468	440	467	390

It will be seen that the breaking strain is the lowest in those cements containing the largest amount of the calcic sulphate, but the breaking strain does not appear to decrease in proportion to the amount of the sulphur salt contained in the cement.

Although a cement containing the impurity mentioned to a limited extent may not at the end of seven days (the usual time in vogue for testing the cement) indicate a high tensile strain, it eventually increases in strength so as to compare favourably with cement of the best quality.

In making some experiments with cement by adding "plaster of Paris" by mixing the two materials in different proportions, I found that if I exceeded 4½ per cent. of the latter the briquettes subsequently made from the mixture either broke up after being placed in water for a time, or, if they retained their shape, they were very much cracked and gave a very poor test. This tends to prove that the crystallising properties of the plaster of Paris causes it to expand and so destroys the cohesive properties of the cement.

As regards the setting properties of cement, ordinary Portland cement should set in about two or three hours, so as to support the weight of a Viéts needle, but to a London cement which had been added plaster of Paris in the following proportions, 1½, 2, 2½, 3, 4½ per cent., and made

into briquettes, the setting properties of the same were restrained from 4½ hours to three days, the slight addition of 1½ per cent. of the plaster of Paris being indicated. The briquette containing the largest amount of the impurity gave a low tensile strain, and when broken I found the interior of the briquette quite soft; it had also cracked very considerably, and the surface of the briquette came off in scales.

I think the experiment goes very far to prove that although the existence of sulphate of lime in small quantities in cement is not hurtful, yet the injurious influence that is exerted by it when it exists in quantities exceeding 3 per cent. ought to render the manufacturer very cautious in purifying his raw material, when considering his production may prove a permanent source of danger to the stability of any work that may be subsequently executed. An irregular mixture of the raw materials would produce a similar effect to that produced by the calcic sulphate, especially where a large excess of the calcic carbonate has been added. The degradation or disintegration is not exhibited, however, in so marked a degree. I would also mention, as regards the presence of free alkalis in cement in small quantities, so far as I have been able to prove, I have not found them to have any injurious effect either in the tests of freshly made cement or in subsequent tests made nearly three years

afterwards. Burnell, in his work on limes, mentions "that General Treussart's experiments upon artificial hydraulic limes would lead to the belief that their quality would be much improved if they were prepared with water in which soda or potash had been dissolved. The subsequent researches of M. Kuhlmann appear to confirm General Treussart's views upon this subject. Even so far back as 1841 M. Kuhlmann recorded the result of some experiments which induced him to propound the opinion that in the cement stones the alkalis served as carriers in the combination between the silica and the lime."

Sulphides are found in all cements to a limited extent. Where it occurs in quantities exceeding 0.5 per cent. of calcium sulphide it may be generally put down to the draught of the kiln being choked, and is due to the reduction of the sulphates. The clinker produced where the draught of the kiln has been obstructed will be found to be of a blue colour, quite different to the bronze appearance that good clinker presents. This colour in the first-mentioned clinker (which contains sulphides also) is due to the presence of a ferrosilicate of iron which gradually oxidises to the detriment of the cement. The ferrosilicate of iron, being a more stable compound, remains unchanged. During the manufacture of cement from substances containing the calcic sulphate in large quantities it will be found that the silicate of alumina (of the clay) will have decomposed the calcic sulphate to a great extent, forming the double silicate of alumina and calcium (which is cement); and even in the presence to the extent of the calcic sulphate mentioned, very little sulphide will be found in the cement if plenty of air has been admitted during the calcining operation. The cracking or disintegration of cements cannot always be put down to its containing sulphur salts, but in many instances it is due to careless working. A perfect mixing of the raw materials is indispensable; the ultimate result almost entirely depends upon this operation. The difference there is in nearly all the various cements made may be attributed to a very great extent to the laxity of the operation named. Of course the complete calcination or perfect decomposition of the mixed chalk and clay must also be taken into consideration.

During the present method of continuous mixing (carried out at all those works where cement is manufactured from chalk and clay), such a regular and consistent quality of cement cannot be expected, for in most instances the mixing is made entirely by guess-work. A certain number of barrows of chalk and mud are emptied into the mixer, and replaces a corresponding bulk of mixed material that overflows on the addition of a fresh quantity to the mixer. In some instances this overflow is tested from time to time by means of a calcimeter, which estimates the carbonic acid, the amount of chalk in the mixture being calculated therefrom. Errors are apt to be made by this process of testing by overheating the slurry in drying it preparatory to testing. Some of the  $\text{CO}_2$  would be expelled. The state of the atmosphere has also to be taken into account.

In no instance is it possible for a man, however experienced he may be, to exactly gauge the mixture of raw materials without testing, when we consider that the moisture in the mud varies in every lot used. Some of it may be taken direct from the boat or bed of clay, or it may have been deposited on the ground for some time, when either wet or dry weather would make a considerable alteration in the amount of moisture it would contain. The same condition would also apply to the chalk, but in a less marked degree.

In the case of cement made from comparatively dry materials, and where the mixing or blending is effected by a dry process, a more uniform control can be exercised, and consequently, as in cement made from the Lias formation, the quality is more regular, and can only be accounted for by the manner in which a perfect mixture of the materials is produced. By an intermittent system of mixing chalk and mud or other materials containing lime, and by a regular system of weighing and testing, a state of perfection in the resultant product could be obtained.

Manufacturers of chemicals know the importance of having the materials they are working upon in proper proportions in order to obtain as perfect a decomposition as possible. The same thing applies to cement, but in a lesser

degree. The difference in the test of the latter (that is, the tensile strain), although appreciable, would not be considered so long as the strain came up to the standard test, which is 1,000 lb. on  $2\frac{1}{2}$  in. sectional area in seven days. Of course, it is quite clear that if, by careful working, the cement could have been made to produce a higher strain by 25 per cent., there would be a decided advantage in it.

In the first instance, for the benefit of those persons who may not be acquainted with the manufacture of cement, I will give the outlines of the process as now generally employed. Cement can be made from any substances containing lime or carbonate of lime in such quantities that will produce after calcination a material having in its composition about 60 per cent. of calcium oxide. At the same time it is essential that the lime-bearing substance should be as free as possible from soluble salts or calcic sulphate. Chalk or limestone is the material that is now chiefly used, but any other form of lime, such as shells or corals, will answer equally as well, the essential point being to have the material naturally in as finely a divided condition as possible, as in the case of chalk, otherwise the grinding of limestone, or the other forms of carbonate of lime mentioned, becomes a rather costly operation. The next process is to incorporate this ground or finely divided lime with a requisite quantity of silicate of alumina either in the form of clay or shale; this is arrived at by the wet process by mixing it in a wash mill, which is a circular trough about 15 ft. diameter, in which a series of harrows are caused to revolve by suitable machinery. The mixture is made of a consistency to admit of its being pumped on to the drying beds, or elevated and allowed to flow on the beds by gravitation. After the mixed product has been dried either by the waste heat from the kilns or, in the case of separate drying beds the fire is caused to pass under iron plates, the dried material is conveyed to the kilns to be calcined. This operation is performed by placing alternate layers of coke and the dried mixture of carbonates of lime and clay in the kilns until they are fully charged, taking care in the first instance to have a sufficient quantity of wood and coke laid on the bars of the kiln to start the fire after the eyes or charging places of the kiln are built up. The charge is then allowed to burn itself out, which it generally does in about three or four days. The resulting product is a hard vitreous clinker, which is then ground by means of suitable grinding machinery and produces the well-known Portland cement. The grinding of this clinker is one of the greatest items of expense in cement-making, the wear and tear on the machinery being very great.

You will now be able to compare the working of the present process of cement-making with the one I shall now describe.

In the first place, in the mixing of the lime or chalk with the clay, it is requisite that as small a quantity of water be used as possible compatible with a perfect mixture of the material. After ascertaining that the proper proportions of raw materials have been used, the slurry is caused to pass through a cylindrical mixer having a series of revolving arms placed therein, or a conveyor would answer the same purpose. During its passage through this mixer, slack, small coke, or breeze is added, and the mixed compound is deposited at the exit end of conveyor or mixer (about the consistency of mortar) on to a band or conveyor that removes it to a place alongside the kilns (the latter being generally built in a line). A guide is placed over the band opposite each kiln to discharge the material as it is required. In commencing the calcining operation a quantity of coke is placed on the bars of the kiln; fire is applied in the usual way, and as soon as there is sufficient heat the mixture above mentioned is placed round it, and gradually covers the coke fire. This charging is continued at irregular intervals, care being taken to place the charge at the point where the flames are breaking through the mass and where it appears the most active. Should the draught be impeded, an iron rod, having a sharp point, is passed through the crust of the burning mass, in order to allow the heat from below to pass through it; this process is continued until the kiln is fully charged. These kilns have been worked continuously, but it has been found better to allow them to burn out in the ordinary way. By so doing, a further

quantity of dried slurry may be decomposed by the heat evolved from the decomposing mixture already in the kiln.

Upon drawing the kiln the clinker will be found of very uniform quality if the operations of charging have been carried out properly. The source of heat having been embodied in the slurry ensures a perfect calcination and obviates the tendency to slag exhibited in most of the usual form of cement clinker. Generally the outside of large pieces present this feature, and at the same time on breaking them the interior of some will be found to be only partly calcined.

The clinker is also in such a friable condition, owing to the product of combustion being compelled to pass through it, that the grinding of the material is reduced to a minimum. At the works I saw in operation, ordinary perforated clay pans were being used with comparatively light edge runners. Millstones are not used in the operation at all, yet the finished cement is in as fine a condition as that produced by any other process of grinding, and is quite as fine as is required. It will be found that the process just mentioned reduces the initial outlay in the erection of works very materially; it does away with the construction of costly kilns and drying beds, and also effects a saving in steam power, as the heavy forms of machinery now in use are not required to grind the clinker mentioned.

A further saving is effected by the use of slack instead of coke (only a very small quantity being used in the calcination of cement by this process). It will admit of works being erected that are far from this source of supply of that article. The kilns used for this process are of the simplest construction; any of the old-fashioned dome kilns now in use will answer the purpose, but as a rule they are rather small, and consequently the operation of calcining is rendered slow.

The finished cement produced by the above process is in every way equal to that made on any other plan.

#### DISCUSSION.

The CHAIRMAN (Dr. HURTER), in inviting discussion, said that he understood that the great difference between the process described and the old one was that in this the fuel was mixed with the slurry and the mixture charged as in blast furnaces, the difference in the two products being that the one was much easier to grind than the other. That would doubtless be of interest to cement manufacturers and to alkali manufacturers who hoped to become cement manufacturers, therefore some questions would doubtless arise.

Mr. E. CAREY said that Mr. Rigby had given them results of experiments with his cement, and that the tensile strength was something like 700 lb. per square inch as compared with 400 or 500 lb. per square inch of the ordinary cement. He would ask Mr. Rigby if he could give them any instances of his cement having been tried under water, and how it appeared at the end of two or three years, trial. The experiments mentioned, he understood, took place in the open air. He (Mr. Carey) had been informed by a civil engineer that some Portland cements had the unfortunate habit of becoming what he called "rotten," undergoing some chemical change which had destroyed their tenacity and rendered them in course of time valueless, the reason being, so he understood from the engineer, that the cement contained an extremely small percentage of sulphide. If the lime from the Chance process contained any sulphide, he would ask Mr. Rigby if he anticipated any difficulty from that cause. Mr. Rigby had also stated that it was generally understood that the presence of a small quantity of alkali was necessary in order to make a good and durable cement. Could Mr. Rigby inform them in what form these alkalis exist in the cement? As far as he could gather from the paper, his method appeared to promise a considerable improvement on the old one, and he hoped it would prove to be so.

Mr. W. P. THOMPSON said that some years ago he had heard of certain so-called "selenitic cements," in which there was a large amount of sulphate of lime. Did Mr. Rigby know anything about that kind of cement, and whether they failed in practice after extended use? Also whether a

small amount of cement mixed with a large amount of plaster of Paris would crack up or do any harm, or whether it would not actually improve the plaster of Paris? He would also like to know whether the works referred to by Mr. Rigby were abroad or in England?

Mr. RIGBY: In England.

Mr. J. W. MACDONALD said he would be inclined to question the engineer's opinion, quoted by Mr. Carey, that cement with even a small quantity of sulphide of calcium was of very little value, seeing that all cements (even the best London cement), contained more or less sulphides, produced by the reduction in the kilns of a portion of the sulphates contained in the clay and chalk. If sulphides were really harmful, he would very much like to know what amount it was unwise to exceed. Mr. Rigby did not estimate the sulphides; possibly they might also have something to do with the weakness of some of the cements he had examined. This new way of burning cement was said to enable them to use slack instead of the more expensive fuel, coke. It seemed that if sulphates and sulphides were so harmful, it was very dangerous to introduce slack, which usually contained much sulphur and its compounds. Possibly it might be right where the ingredients were pure, but such ingredients as Chance's lime mud already contained a great deal of sulphur, so that the mixing of slack with the "slurry" would produce a greater quantity of sulphur compounds in the cement. He thought that where the ingredients were pure, impure coal could be used, but if they had bad stuff to start with they should use the purest coke possible.

Mr. JAMES FORT asked whether a trial had been made for the making of cement from the spent lime of gas-works, if so, what results were obtained? The quality of cement produced by Mr. Rigby appeared rather poor, and not adapted for general use; but as it was from a waste product which had been brought to some utility, a considerable amount of business might be done by employing it in the manufacture of concrete paving. Concrete "flags" were used in several large towns, particularly in Warrington, where the slag from the destructors was ground up, mixed with common cement and formed into flags, &c. The Corporation thus got rid of the refuse from the ash pits and dust heaps.

Dr. HURTER asked whether  $4\frac{1}{2}$  per cent. of sulphate of lime mixed with the finished cement would not be much more harmful than an equal amount of sulphate of lime contained in the raw materials and intimately mixed therewith. Also whether the waste limes were always sufficiently free from magnesia, since that substance had been found to interfere with the resistance of the cement to the action of sea-water. Also whether lime mud from Chance's process must of necessity undergo a process of purification, and if the profits on the manufacture of cement were sufficient to cover the costs of such purification?

Mr. RIGBY, in replying, said, in regard to trying the cement under water, the briquettes when made for testing were always placed in water for six days. The cement had been used by contractors and corporations for gas-holder reservoirs, quay walls, and for all purposes where cement was required. As regards the presence of alkali in ordinary London cement, he thought it existed as aluminate or silicate of soda. Selenitic cement could scarcely be called a cement. It was a plaster, and was made by mixing borax or alum with plaster of Paris in certain proportions, with subsequent heating and grinding. The sulphate of lime sufficiently explained the disintegration of cement; he did not think it was sulphite in London cement. In London cement (the average of two samples) he found 0.20 per cent. of sulphide, in cement made by him 0.35 per cent., and in another sample of his 0.19 per cent., so that so small a quantity of sulphide could not possibly affect the cement. When the impure muds were properly treated the sulphates and sulphides could be eliminated. Sulphur in the sulphide of iron was carried away in the calcination as sulphurous acid.

In using Chance mud which had been made for some time the sulphide of iron was gradually oxidised into

sulphate, which in its turn was decomposed, forming sulphate of lime. Chance's waste should always be treated freshly to extract the sulphur. He did not think the use of slack instead of coke would much affect it or put any more sulphate or sulphite in except a very inferior fuel were used.

In the ordinary way of drying the slurry they took the hot gases over long beds, and more sulphurous acid was evolved from burning coke by carrying the gases that way than by putting the cement under the burning mass. On the other hand, he pointed out that cinders could be used, if washed, instead of slack. Breeze could also be used if thought necessary.

It would not be a difficult matter to purify lime from gas-works by carbonating it in the usual way. By passing carbonic acid through the gas lime the sulphide would be eliminated as sulphuretted hydrogen. The carbonate of lime could then be washed and treated in the usual way and would make good cement. He did not think it had been purified.

With regard to the action of sea-water on the cement, he thought he had mentioned that it had stood the trial, but it had not been left in for a long period. Cement had been sold to steam-tug owners who were perfectly satisfied with it.

As regards magnesia in cement, he had read that the action of sea-water was detrimental, but in New York cement which contained 10 per cent. of magnesia was made, but he believed it contained more. How far sea-water would affect it he could not say, but he believed it would have some effect.

If Chance mud were treated direct, the extra cost would not much affect the cement profits. But it would not stand much handling. It was a simple matter to purify Chance's mud. Two samples out of six he had made direct without purification at all turned out satisfactory.

He could scarcely say whether if a small amount of cement were mixed with plaster or scintic cement it would do good or harm. If they used a large quantity of sulphate of lime it would cover it, and it would be exactly as if it were not there. If they used equal quantities it would fall to pieces in water.

Science and Art Department might exercise over those local authorities who adopted the Act. Under these circumstances the Committee thought it advisable to invite Mr. Mather to be present at this meeting, so that he might be able to fully explain the application of the Act, as probably no one could speak with greater authority on this subject. Unfortunately Mr. Mather had been prevented from attending, but he had sent the following letter, which very clearly and conclusively set forth his views on the Act. Mr. Wm. Mather, M.P., wrote:—

"The apprehension of the Science and Art Department becoming master of the situation by the 'Technical Instruction Act' is obviously entertained by all the opponents to the proposal for levying the rate. This apprehension is absolutely groundless.

"The object of the Act is to enable local authorities to establish or aid schools of science or art, with special branches of instruction adapted to the requirements of their respective districts; and the local control of such schools is as safely guarded under the Act against interference in management on the part of the South Kensington Department as municipal control is guarded against interference of the Local Government Board.

"The 'science and art' classes hitherto established have derived their income almost entirely from the grants of South Kensington and school fees. The grants are bestowed for results of certain examinations, the character of which I have never approved. The system of examination has been accommodated to *class* instruction because the Department has mainly encouraged the establishing of classes all over the country, rather than the promotion of practical *schools* of science and art, in fewer centres, fully equipped with apparatus and appliances for experimental and laboratory work. But where public subscriptions, or individual generosity, have enabled the managers of such classes to add the premises and appliances necessary for sound and thorough training—as, for instance, in the case of the Manchester Mechanics' Institute, formerly consisting of science classes, now a technical school—the Department has never exercised the slightest control though continuing its grants for certain results.

"In like manner the science school of my firm has always received an annual grant from the Department for certain results, but the teaching is adapted beyond this to the requirements of our apprentices, at our own cost, and managed in the best way we can conceive of without reference to the Department.

"Again, the Birmingham School of Art receives a large grant from the Department, but it is a municipal school maintained by the Corporation, and is controlled entirely by the council on a system they deem best. These illustrations show that the obtaining of a grant does not, even at the present time, restrict the operations of a school to the subjects or methods contained in the directory of the Science and Art Department. An efficient and thoroughly-equipped school embraces, of necessity, all the Department requires, to qualify it for the Parliamentary grant, without adapting its teaching to any method recommended by the Department.

"If there are no other means at the back of a school but the Department grant and low fees, of course the teaching will be feeble and unsound and the effect thereof transient. This, in my opinion, is the condition of most of the science and art classes throughout the country. But the responsibility for this state of things no longer rests with the Department. The Technical Instruction Act, though incomplete in its range, at least enables every community throughout the country to supply efficient science and art schools, or to aid such as exist, for its industrial population.

"The unstable support given to the few efficient schools we now possess, dependent on subscriptions or individual generosity, ought to be immediately supplemented by steady and substantial aid from the local authority. The Parliamentary grant will be bestowed as heretofore, though the Act provides (clause 3), and very properly, that the Science and Art Department may alter its conditions. The sooner a change is made the better, for the grants are now given for results of a most unsatisfactory kind. Any change must necessarily be in the direction of encouraging more

SESSION 1890.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

Meeting held at Victoria Hotel, Manchester, on  
Tuesday, 4th March 1890.

MR. IVAN LEVINSTEIN IN THE CHAIR.

## DISCUSSION ON THE TECHNICAL INSTRUCTION ACT, 1889.

THE CHAIRMAN said that at the last meeting a discussion took place on the Technical Instruction Act, and that some objections were raised by members to the control which the

sound and practical instruction, such as the rate-aided schools can well afford to supply.

"Now, let us look at the Act with a view of finding some support for the assertion that the Science and Art Department will be 'master of the situation' in the future.

"The sub-section (*d.*) of clause 1 provides for aid to be given to schools for the time being in receipt of grants from the Science and Art Department. This is a guarantee to the local authority that the claims of such schools have at least some title to be considered. But the amount of aid depends entirely on the local authority. It may decline to entertain the application on various grounds. The 'requirements of the district' are to be kept in view; the quality of instruction, as compared with other such schools, must be regarded, and questions of management adjusted satisfactorily to the local authority.

"A further sub-section (*f.*) of clause 1 provides that differences of opinion may be referred to the Department of Science and Art, should they arise between the managers of any school and the local authority. The determining of the question is limited to giving an opinion which the Department has no power whatever to enforce. The function of the Department will be purely consultative on questions of this kind, and probably seldom used.

"In these two instances where the Science and Art Department is mentioned in the Act there is no ground whatever for apprehension that local control will be interfered with.

"In clause 3 the Department is again named, but I have already dealt with this instance. It does not affect local control in the least degree.

"In clause 8 we have a broad definition of technical instruction and manual training. The clause is drawn to protect a local authority against being surcharged by the auditor for having bestowed aid out of the rate on a school, in which, according to his view, subjects were being taught not included in the terms of the Act. To prevent all possibility of dispute, or any perplexity to the local authority or its legal adviser, a complete list of the subjects of instruction which a local authority may desire to aid—beyond those mentioned in the directory of the Science and Art Department—must be sent to the Department. The subjects named in the directory are *ipso facto* included in the terms of the Act, and the auditor cannot question the right to aid them. It is obvious that this obligation on the part of the local authority is expressly imposed for its own protection and assistance. The only possible control of the Department will be limited to a rejection of any subject in the list sent up which did not come within the scope of the Act. The power to give an authoritative interpretation of the scope of the Act must of course rest somewhere. A court of law is the only alternative, unless a department of the State has this power.

"Now, it would be altogether misleading and unreasonable to assert that a department of the State, in performing this function, necessarily becomes 'master of the situation.' It will simply interpret what may be done under the Technical Instruction Act, as the Local Government Board interprets what a local authority may do under the Municipal Acts. Were some authority not created by the Act which could define, for instance, what character of workshop practice and the use of tools was included in the term 'technical instruction,' it might be that an auditor would hold that a certain trade was being taught in some rate-aided school. It is most important that the trades unions throughout the country shall have ample security that the Act will not be used in any way other than for strictly educational purposes. This security is fully given by the power vested in the Department of rejecting any subject in the list submitted by a local authority which is outside the scope of the Act. In the exercise of this function the Department has no power whatever to dictate what shall be taught under the Act or to inspect the methods of teaching. All or any subjects covered by the Act may be aided by a local authority according to the requirements of the industries of the locality without let or hindrance. The Department can only assist local interests when consulted, and cannot thwart them at any time under any pretext whatever. The initial inconvenience

or delay in applying to the Department to lay on the table of the House a list of subjects which a local authority intends and determines to encourage the teaching of out of the rate, is but a slight matter, and once done the Department may never be appealed to again.

"Suffice it to say in conclusion—and I do so positively without fear of authoritative contradiction—that from every point of view the most complete control will ever rest with the local authorities and local managers over all schools for technical instruction aided by the local rate under the Technical Instruction Act. All beginnings are more or less difficult. This Act will encounter some difficulties no doubt, but I am sure they will not be serious if not created by unreasonable opponents. In the course of even a short time, amendments may be suggested from experience which Parliament will readily sanction. Meanwhile we ought to use 'whatever of good the present brings,' and so make the best and surest preparations for better things to come."

The CHAIRMAN went on to say that the Act appeared to him to be the practical outcome of the desire of those who were in favour of more extended and efficient technical instruction. Schools in which technical subjects and scientific principles pertaining to industries were taught, never could be self-supporting for the simple reason that the fees would have to be fixed at such a high rate as to make them prohibitory to the poorer students, and thus defeat the primary object, viz., the extension of the teaching of technical subjects to the masses. The primary object of the Act was to provide a fixed monetary contribution out of the rates for the purpose of technical instruction. Whatever its minor faults might be, members could hardly object to the principle of the Act, and no doubt, as necessity arose, any shortcomings which might come to light would be amended.

Mr. CARPENTER said they were all aware that very recently a strong body of memorialists, representing all the most important educational institutions in the city, had waited upon the town council of Manchester, praying that it would adopt the provisions of the Technical Instruction Act, 1889, and he hoped that his remarks would not be out of order with the resolution to be submitted to that meeting requesting that a memorial should also be presented from the Manchester Section of Chemical Industry to the same effect. To Mr. Mather they were indebted not only for his share in the Bill as it stood, but at various times for his earnest advocacy of its adoption, and for his constant endeavours to remove the misconceptions that still existed in the minds of many as to the real powers conferred by the Act. The history of some of these misconceptions in Manchester it might be interesting and instructive to trace. To begin with, when the Bill was before Parliament in August last year, the deputy town clerk called the attention of the Parliamentary Committee of the Corporation to an amendment proposed by Mr. Mather, making it compulsory for local authorities to contribute out of the rates, with the result that the Corporation petitioned against the proposed amendment. Mr. Mather, however, withdrew his amendment from the paper before committal of the Bill, and the whole action of the Corporation Parliamentary Committee therefore fell through. This might cause people to think that because the Corporation had petitioned against the Bill there must be some objection to it, whereas the only objection was simply as to whether they "*may*" or "*must*" contribute out of the rates, the Bill as drawn by the Government having been always an "enabling" Bill. Early in September the National Education Association held a meeting, which was addressed by the Hon. Lyulph Stanley, who unfortunately made a very severe attack upon the Bill, stating, *inter alia*, that it assisted denominationalism, and doing all in his power to raise the denominational bogey. Mr. Mather was not able at the time to reply, but on September 13th he did reply, and being at some distance from home he was not aware of the action which the Corporation had taken in the matter. He (Mr. Carpenter), on September 12th, explained the real state of the case as above detailed. On November 27th a conference was held in Manchester at which, in addition to the explanatory address of Mr. Mather, Sir Henry Roscoe read an

address showing how far the Act had been put in operation, and General Donnelly was present from the Science and Art Department, South Kensington, but he certainly was not too communicative in his replies to the questions addressed to him, and so not only failed to remove previously existing misconceptions, but unfortunately was the innocent cause of establishing fresh ones in the minds of some of those who were present. The next feature that presented itself was the memorial of the various bodies who hoped to obtain grants under the Act, led by Mr. Oliver Heywood, on behalf of the Manchester Technical School; and looking over the Manchester papers he was surprised to see a letter written by a Bradford gentleman, in which town the Bradford Technical School had been applying for a grant, in which the writer seemed to be labouring under the same misapprehension as to the powers of control exercised by the local authorities under the Act, as he stated that the Bradford Corporation had allowed the memorial to lie on the council table with contempt, and he hoped the Manchester Council would assume the same attitude as had been shown to the Bradford memorialists. He (Mr. Carpenter) hoped this spirit did not prevail in Manchester. Another feature which he desired to bring before them was the difficulty which evidently existed with regard to school boards. He knew that an opinion prevailed among some of the members of the Manchester School Board that because the Act did not give them everything—that therefore it was badly drawn, and should not have been passed. He thought that those school boards which had not made use of the powers which they already possessed should not cry out. Take, as an instance of what can be done in technical instruction, the action of the Birmingham School Board in establishing, in conjunction with the Science and Art Department, South Kensington, their advanced classes. The strong point about the Birmingham system was that the pupils in these technical classes, who had already gone through the higher standards, were obliged to enter for not less than two years, and optionally for three, allowing ample time for sound and methodical instruction, and he thought that was the basis on which all technical instruction should proceed.

Dr. BAILEY said, as he had introduced this question at the last meeting, perhaps it was due to those present that he should say something about their position in the matter. A sub-committee was appointed last month to draw up a memorial for presentation to the City Council urging them to support the Bill, and it had been his intention to have brought this before the last meeting of the Section, but being informed on good authority that the Science and Art Department would dictate subjects, appoint examiners, and practically control the working of the Act, he declined to have anything further to do with the memorial. However, Mr. Mather now told them in his letter that the apprehension of the Department becoming masters of the situation by the Act was absolutely groundless, as the Department would simply act as a board of reference. Under these circumstances it seemed to him to be very desirable that they should memorialise the City Council in the strongest manner possible, urging them to adopt the Bill. They had in Manchester a number of schools engaged in technical instruction, and this was also encouraged, to some extent, by the City Guilds, but in neither case was adequate support given to such teaching. They, as a Society engaged in the practical application of science, recognised that the subjects taught by the Science and Art Department did not, in so far as referred to the elementary stage (and a very large majority never got past this), come up to such a standard as would enable a student even to follow up those studies which would be useful to him in his special industry, and it was in this respect they felt that the Department, whose system was such as to encourage the most superficial knowledge in a multitude of subjects rather than sound knowledge in two or three, was not the proper body to carry out the provisions of the Bill. Whatever advantages or disadvantages they might suffer under with regard to Germany or other countries, there could be no doubt about the fact that such classes as were held in those countries were attended by those actually engaged in industrial pursuits, whereas, in this country a very large percentage of those

who attended science classes were school boys and persons who were unconnected with the industries. Yet there must be, in Manchester, 50,000 people engaged in industries who would derive benefit from a knowledge of those scientific principles and by a further knowledge of the subjects connected with their particular industries. But from inquiries he had made, the number who were receiving scientific instruction did not exceed 5 per cent. of those so engaged. Now, these were facts which ought to appeal to everyone, and especially to the City Council, and, unless such a matter was dealt with by those immediately interested, it is not likely to be dealt with by any central organisation, and for these reasons they were fully convinced that the City Council had a great work before them, if they could efficiently carry it out. What was wanted was a bond of union between the civic authorities and manufacturers in order to make technical education in this district a practical success, and for this reason he hoped the resolution he had to propose would be well supported.

Mr. GRIMSHAW said that as there were a number of gentlemen present who were not members of the Society, but who were directly interested in the teaching of technical subjects, he would offer a few remarks as to the position which the Society held in the matter. He believed he was right in stating that the point which they had wished Mr. Mather to enlighten them upon was:—Whether, under the Technical Instruction Act of 1889, education could be given in a way not prescribed by the syllabus of the Science and Art Department and in subjects not contained in that syllabus? If such was not the case, then he believed that the Manchester Section of the Society would not concern itself in any way with the Act, or waste any time in considering its provisions. The Section only professed to speak for the chemical industries, as they did not know the exact form of technical instruction required by the cotton, iron, coal, and engineering trades, or others, except at the points in which those trades touched the manufacturing of chemicals. With regard to technical instruction having for its object the elevation and improvement of chemical industries, they had an opinion in which he believed they were inclined to be rather bigoted. At a meeting of this Section in February 1889, before the passing of the Act, a pretty general opinion was expressed that what they wanted to see erected was a system or a set of institutions by means of which they could have professors of industrial chemistry, and in addition highly-educated masters and owners of chemical works, and a superior class of technically-educated managers and foremen. With regard to the workmen engaged in chemical industries, they considered that a good elementary education, with due attention to scientific subjects as part of the curriculum, would render them fit to do their best as workers in chemical yards when they had had a few years under the properly equipped foremen, managers and masters, whom they wished to create. Not that the chemical technologist was non-existent at the time, but where was the professor of technical chemistry? Mr. Mather would see that if this position was correct, the chief concern of this Section was not with elementary education and what could be taught under the South Kensington syllabus, but “Whether it was impossible for new authorities to use new powers to commence a system of scientific technical education outside and above the Science and Art Department curriculum.” Now, when this Act had got into operation, he hoped there would be more inspection and less examination. They also wanted higher elementary and good secondary schools, and technical schools, and the production of better teachers. He believed the City of London Guilds, more particularly the Finsbury School and Central Institute, did more fully approach the realisation of a proper scheme of education than the South Kensington Department. Instruction under the Act should be more practical and less professional; for true technical instruction resided somewhere between the secondary schools—of which this country was almost devoid—and the colleges. What was wanted was something in place of the mechanics’ institute, where sound technical instruction at a small rate of cost could be obtained. To-day they had the merest shadow of such places, and they felt curious to know whether the penny provided under the Act would be the shadow of the

money which would be provided by a far-seeing Government to accomplish such a nationally-important object. He knew the difficulties which Mr. Mather and Sir Henry Roscoe had had to deal with in the House of Commons. What was really wanted was home rule in technical education, so that each locality could deal with its own industries, and he was very glad that Mr. Mather had given them some hope of this being accomplished under the Act.

Mr. J. H. REYNOLDS, Secretary of the Manchester Technical School, said he was himself engaged in administering technical education in the city of Manchester, and no one knew better than he did how deficient were the means at the command of the technical school to fully accomplish the object its council had in view in establishing an institution where a thorough system of technical instruction could be carried out. The *1d.* in the *£* allowed by the Act would produce about 10,500*l.* a year, but the memorialists who recently approached the Corporation thought that a  $\frac{1}{2}$ *d.* rate would be sufficient to meet present demands. He fully concurred in the Chairman's remarks that no thorough system of technical instruction could be made self-supporting, as the expense of workshops and appliances would be too costly. He agreed with Dr. Bailey, that only about 2,500 students in the city and district took up the study of technical subjects with a view of improving their knowledge with regard to their respective trades, and that the bulk of the students attended the science and art classes simply for the purpose of extending their general knowledge. Only those practically engaged in the various industries would be able to say in what way and to what extent technical instruction benefited them; and for this reason he thought no such system could be usefully and wisely administered by the school board, which was elected for a very different purpose. He was of opinion, therefore, that the City Council, in association with a committee of commercial and manufacturing experts, could deal with the matter more efficiently. If the Act was to be of any value it must be administered by those who fully understood local requirements; but this could not be effected if the matter was left in the hands of a central authority in London, which could not be in touch with those mostly interested in carrying out the provisions of the Act. There was, however, no real ground for apprehension that the Science and Art Department would unduly interfere in the administration nor with the subjects dealt with under the Act.

Mr. J. S. THORNTON said there was a widespread feeling that under the Act the influence of the Science and Art Department would be confined to schools in art centres, and if that were so he agreed with Dr. Bailey and Mr. Grimshaw that that would be contrary to the meaning of the Act. Those gentlemen were very much convinced of the wisdom of the Science and Art Department, and their proposal seemed to be that a scheme should be adopted which would make the Act more widespread in its influence and increase its power. The Science and Art Department went in for many things, but not much of any, and in his opinion it was an Augean stable which required cleaning out. The question was:—How far would the adoption of the Act, that is to say, the extension of the science and art examinations, assist technical education in the direction they so much desired? The report of the Commissioners on Technical Education stated that in our staple industries we were still ahead of other countries, and that in not one of our special lines did we need much improvement; but the question was:—Would the Science and Art Department produce a supply of such chemists as our manufacturers of beetroot sugar required, and such as Germany possessed? The present system of examinations encouraged teachers to make money out of them, and this debased both teacher and pupil.

Mr. Wm. THOMSON wished to know whether there was any stipulation as to how the money raised by levying the rate was to be spent? He contended that it was quite impossible to teach people trades by any system of technical education. If they wished to learn a trade they must go into the workshops. Technical education ought to aim at teaching the fundamental principles involved in

all trades. He thought the Science and Art Department would be the proper authority to control these matters, as they would have more experience than would be likely to be found in any local body of men.

Dr. BAILEY then moved, and Mr. GRIMSHAW seconded, the following resolution, which was put to the meeting and carried unanimously:—

"That this meeting of the Manchester Section of the Society of Chemical Industry, having considered Mr. Mather's statement, expresses its hearty approval of the Technical Instruction Act, 1889, and desires the committee of the Section forthwith to prepare and arrange for the presentation of a memorial to the mayor and town council of Manchester, praying them to carry out the provisions of the Act."

## Newcastle Section.

Chairman: T. W. Stuart.

Vice-Chairman: P. P. Bedson.

Committee:

A. Allhusen.  
G. T. France.  
G. Gatheral.  
John Glover.  
T. W. Lovibond.  
John Pattinson.

H. R. Procter.  
B. S. Procter.  
W. W. Procter.  
W. L. Rennoldson.  
C. H. Ridsdale.  
J. E. Stead.

Hon. Local Secretary and Treasurer:  
Dr. J. T. Dunn, The School, Gateshead.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

Meeting held in the College of Science, Thursday,  
March 6th, 1890.

DR. BEDSON IN THE CHAIR.

### ON GANTLER'S METHOD OF ESTIMATING TANNIN.

BY HENRY R. PROCTER, F.C.S.

It must be admitted that a rapid and exact method of estimating tannin in dilute solutions is still a desideratum, and it was therefore with much interest and some hopefulness that I began experiments with the method recently published by F. Gantler (*Zeits. f. angew. Chem.* 1889, 20; *Jour. Soc. Dyers and Colourists*, V. 176), in which the determination is made with permanganate in a boiling solution. He employs a solution of permanganate of about 4 grms. per litre, acidifies 10 cc. of the tannin infusion with 10 cc. of dilute sulphuric acid (strength not stated), and adds the permanganate in small quantities to the nearly boiling solution, pausing between each addition till decolouration takes place. When in the end a precipitate of manganese hydrate forms which no longer disappears even on vigorous boiling, about 1 cc. of permanganate is added in excess, and the strong boiling is repeated several times, which causes the disappearance of the red colour, and the separation of a dense brown precipitate. This is then removed by the addition of a known quantity of oxalic acid, and the titration completed in the usual way without boiling, and the permanganate equivalent to the oxalic acid is deducted.

Gantler shows by a series of estimations that the result is not materially affected by the concentration of the permanganate employed or the strength or quantity of the tannin, and finds as the average result of his experiments that 1 gm. of pure tannin consumes 3.988 grms. of permanganate, while he states that the amount reduced by other tannins is not very different, but that on this point he is experimenting further.

My experiments have so far been confined to solutions of pure tannin and infusions of oak bark, and in the main bear out these results; but I find, as indeed was rather to be anticipated, that the amount of permanganate consumed is materially influenced by the excess of permanganate added, and the amount of boiling to which it is submitted. In this way I obtained with an infusion of oak bark results varying from 17.6 cc. to 19.8 cc. of permanganate, and it is probable that still higher figures would have been given by employing still greater excess, or repeating the boiling and addition of permanganate. Gantler assumes that he obtains a complete oxidation, but calculating from received formulae, 1 molecule of tannin,  $C_{12}H_{10}O_6$ , would require 24 atoms of O for complete oxidation to carbonic acid and water, and this is equivalent to 4.7 grms. of permanganate for 1 gm. of tannin. No possible theoretical changes in the formula would materially affect this result, which is in agreement with the observed percentages of ultimate analysis. It is therefore clear that towards the end of the reaction some product is formed which is very difficult of further oxidation, and it also seems probable that in presence of manganese sulphate, dilute solutions of permanganate on long-continued boiling are gradually decomposed with loss of oxygen. At any rate, if Gantler's method be applied to the oxidation of oxalic acid, results much in excess of the truth are obtained.

It is probable that by adherence to a rigid scheme of operation, concordant results might be obtained, but such results could have at best but a comparative value, and no greater claims to accuracy than those of the Löwenthal method, which, when a standard solution of pure tannin is treated in exactly the same way as the infusion under examination, gives fairly satisfactory and reliable results.

I have had no opportunity of consulting Gantler's paper in the original, but if the translation in the Journal of the Society of Dyers be a correct representation of his views, it is quite clear that he has not fully grasped the principle of the Löwenthal method as improved by von Schroeder. He speaks of part only of the tannin being oxidised in this method, but as I have explained in a previous paper read before this Society (this Journal, 1886, 79—82), the whole of the tannin present is oxidised, though not to its ultimate limit of carbonic acid and water, but to some intermediate products which have not been determined; and the office of the indigo is not merely that of an indicator, but of a regulator of the degree to which this oxidation is carried. I need not repeat details which have been fully explained before, but the gist of von Schroeder's improvement is that the solution under examination is directly compared with one of pure tannin titrated under exactly the same conditions, and therefore oxidised in the same way, and he has specially insisted on the point that such comparisons as Gantler makes of the absolute quantity of permanganate consumed are of no scientific or practical value. Much may be said against the special so-called "one cubic centimetre" method which von Schroeder adopted as his working process, but nothing against the sound system of direct comparison which he advocated. Gantler is also quite wrong in his assumption that the Löwenthal method, properly executed, does not give results very approximately agreeing with the gravimetric one, and seems quite to have overlooked the fact, well-known to all chemists who have examined the subject, that in dealing with tannins other than gallotannic acid it is necessary to employ reduction-factors dependent on the nature of the tannin in question, that of oak bark consuming approximately only two-thirds as much permanganate as gallotannic acid.

Gantler also states that by his method the amount of matter not tannin estimated is so small that for technical purposes it may generally be neglected. This is decidedly incorrect, as in four samples of oak bark which I examined by this method it averaged over 25 per cent. of the total,

and it is to be borne in mind that while Löwenthal's method is practically unaffected by any gelatinous matter which may be dissolved from the hide powder used in removing tannin in order to estimate by difference, the same is by no means the case with Gantler's, and gelatine precipitation, which as a technical method with Löwenthal is rapid and satisfactory, is with Gantler not to be thought of. While I do not deny the possibility that a useful method may ultimately be based on Gantler's idea, I think I have said enough to prove that in its present condition it cannot supersede Löwenthal's.

#### DISCUSSION.

Dr. DUNN said that there was no doubt as to the evolution of free oxygen when permanganate was boiled with solutions of manganese salts in presence of acid, even with dilute solutions. The result varied with the proportions of the two. So long as the proportion of permanganate was less than that corresponding to the equation—

no free oxygen was given off, and the whole of the available oxygen of the permanganate was present in the precipitate of manganese dioxide; but as the proportion of permanganate increased, a gradually increasing amount of oxygen was given off, till the state of things represented by—

was reached, after which any excess of permanganate appeared to be unaffected.

Mr. PROCTER thought that perhaps the acid became sufficiently concentrated, during the boiling in Gantler's method, to act on the manganese dioxide formed, because in practice the amount of permanganate added was never so great as that in the first equation given by Dr. Dunn.

Dr. BEDSON inquired whether the actual products of the oxidation of tannin by permanganate had been investigated, as the amount of oxygen used, according to Mr. Procter, was always less than that needed for the complete conversion of the tannin into water and carbon dioxide. He suggested as a probability the formation of one of the hydroxybenzoic acids, themselves compounds of considerable stability.

Mr. PROCTER then drew attention to a curious case of corrosion of a glass bottle, which had been used to contain potassium carbonate solution, and in which this solution had stood without being used for some years. The whole upper part of the bottle, from the level of the surface of the liquid upwards, was found to be roughened and corroded, while the portion in contact with the solution was not so.

Dr. BEDSON then gave a demonstration of a gas analysis apparatus. The apparatus was practically that of Dittmar, with a modification in the mode of transferring the gas from the laboratory tube to the absorbing pipettes and back again. This consisted of an ordinary Hempel's pipette, provided with a three-way tap between the reagent bulb and the capillary tube. The capillary tube, the reagent bulb, and a small moveable mercury reservoir can thus be made to communicate with one another two at a time, so that the capillary tube can be filled with mercury, and the transfer of gas made in both directions without allowing any of the reagent to pass the tap and get into the capillary tube.

## A BRIEF HISTORY OF THE CHEMICAL MANURE INDUSTRY, WITH SPECIAL REFERENCE TO THE NORTH OF ENGLAND.

BY JOHN MORRISON, CHEMICAL ENGINEER, NEWCASTLE-ON-TYNE.

**General Features.**—Liebig, in his "Agricultural Chemistry," published in 1840, states that "perfect agriculture is the true foundation of all trade and industry," and "of the riches of States." In it he further prophesies that "a time will come when plants growing upon a field will be supplied with their appropriate manures prepared in chemical manufactories—when a plant will receive only such substances as actually serve it for food, just as at present a few grains of quinine are given to a patient afflicted with fever, instead of the ounce of wood which he was formerly compelled to swallow in addition." Liebig likewise in the same work makes the important declaration that "the most practical method of effecting the division of bones (*for manurial purposes*) is to pour over them, while in a state of fine powder, half their weight of dilute sulphuric acid, sprinkling the acid mixture before the plough."

**Origin.**—To the latter statement may be credited the origin of the artificial manure industry, though it should not be overlooked that so early as 1817 Sir James Murray had experimented with, and had proven the manurial value of soluble phosphates.

In the year 1838, when the British Association first met in Newcastle-on-Tyne, Messrs. Lawes and Gilbert began their agricultural researches. And in the same year Peruvian guano was first imported into England as a manurial curiosity, being sold at 20*l.* per ton.

Guano was at first, however, regarded by English agriculturists with considerable distrust, so that its use did not rapidly extend until in 1841 it was specially brought before the notice of the Royal Agricultural Society. After this introduction its sale rapidly increased, so that in the year 1863, when the British Association for the second time met on Tyneside, its annual British consumption had reached about 100,000 tons, its price having descended also to about 12*l.* per ton. Mr. Lawes, at Deptford, and Mr. Procter, at Bristol, began manufacturing chemical manures about the year 1843, the former having discovered in dissolved mineral phosphates an excellent phosphatic substitute for Liebig's dissolved bones. And as this was only about a year before Dr. Richardson commenced the business on the Tyne, the North of England was pretty well to the front in the race.

**Prejudices.**—The trade in those early days, however, was looked upon with considerable suspicion. Agriculture had been carried on for centuries without any adventitious aids, and what it had never hitherto seemed to want it was thought it could never hereafter possibly miss. The digestive organs of his own sheep and cattle formed the farmer's universal mixing machine, and the excreta of his live stock, with occasional doses of marl, lime, and seaweed when obtainable, comprised his sole manurial repertory. And being very conservative in his disposition, and very much wrapped up in his ancestral methods, he hated innovations with a perfect hatred, regarding in the light of a personal injury the advocacy of revolutionary agencies of which his respected forefathers had never so much as dreamed.

In 1863 the total British make of dissolved manures had reached about 200,000 tons, of which Mr. Lawes himself produced about a tenth. Indeed, so important had the English manure trade then become, that Liebig trembled, and solemnly declared that England was "robbing all other countries of their fertility;" that "in her eagerness for bones, she had turned up the battle fields of Leipzig, Waterloo, and the Crimea;" that "she annually removed from the shores of other countries to her own the manurial equivalent of three millions and a half of men;" that "like a vampire she sneaks the heart blood from nations without a thought of justice to them;" and that "it was impossible that such iniquitous interference with the Divine order of the world should escape its rightful punishment."

Liebig was not evidently a believer in international commerce.

**Mineral Phosphates.**—The introduction of prepared bone materials formed the dawn of the chemical manure trade, as the introduction of mineral phosphates formed its sunrise. Without the latter, chemical manuring must have been crippled almost in its infancy. Had not, indeed, dissolved bones quickly competed with the earlier guanos, the price of guano must have tremendously increased. And had not mineral phosphates risen to the relief of bones, the price also of bones must have rapidly advanced. When all were in use together, it became purely a question of the survival of the fittest. And now over 40 years since the contest for supremacy began, almost the youngest combatants seem the victors in the fight.

**Worthless Compounds.**—The chemistry of the early manure trade was not of a high order. Lots of people with a greater excess of assurance than of honesty ransacked almost the heavens, the earth, and the sea to discover refuse which, cheaply wrought into friable condition, they might ostentatiously palm off upon the British farmer as genuine manure. Not a few merchants seemed verily to believe that guano itself was specially created but as a flavouring to their sand, clay, or pulverised bricks. And the farmer was unfortunately then too ready to give an absurd price for scandalous commodities if only impregnated with a good solid stink. One manure, largely sold about the year 1856 at 12*l.* per ton, was for the most part apparently a mixture of burnt ore and nitre cake, and even years later than that, mixtures were widely disseminated which, though pleasantly remunerative to the seller, could but be of infinitesimal benefit to the consumer.

**Dissolved Bone Compounds.**—But the yearly increasing demand for chemical manures, and the corresponding increase in the value of bones, tended perhaps to one regrettable result. This was the introduction of materials other than simple bones and acid into manures retaining the original name of *Dissolved Bones*. The augmenting scarcity of bones of course sternly demanded some cheaper substitute. Consequently a class of manures rapidly came into use possessing certain well-defined mechanical characteristics, and a certain well-recognised chemical analysis. That the successful production of such manures has immensely benefited the farmer, there can be no question. And that consumers have been thoroughly satisfied as to the results from their use is proven by their widespread popularity, and the enormous annual demand for them. But that for five and twenty years they have been associated with a name which does not accurately describe them is certainly a pity.

Bones have, ever since the manure trade began, been in some sense regarded as the standard of phosphatic purity. And yet when calcined and sold as bone ash their purity is substantially inferior to that of various mineral phosphates now in extensive use. Phosphatically, indeed, it is difficult to see the difference between either bones, bone ash, or spent bone charcoal, and good mineral phosphates of similar analysis. And this especially when, as in most cases, the mineral is really a fossilized bone phosphate, and when, as is now usual, it is before treatment very finely ground—much more finely indeed than bone materials. Neither is it easy to perceive the difference—manurially considered—between two fertilisers of similar analysis, but solely produced in one case from bones and acid, and in the other compounded of bones, fish, or other guanos, animal matters, mineral phosphates, and acid. So far as the soluble is concerned there *can* be no difference, while as to the insoluble it is for the most part a question of mechanical division.

**Pure versus Impure Dissolved Bones.**—In the Merchandise Marks Act, 1887, chemical manures were not apparently contemplated, and how this Act will eventually deal with the above case of dissolved bones is by no means certain. Something, however, should speedily be done. At present it is utterly beyond the power of any commercial analyst to categorically certify the purity of many samples of professedly pure dissolved bones. A chemist may be able to

express an opinion as to the presence or absence of mineral phosphate in the insoluble portion, or generally as to the composition of the manure being solely *animal*. But to positively declare that any given sample is composed solely of bones and acid is beyond his powers. And his position is materially aggravated by the many varieties of local and foreign bones and meals now in daily use. This is very burdensome to the conscientious manufacturer (and surely he is in the majority), for the manures he designates and supplies as pure have to compete against others much more cheaply produced, but which are of similar appearance and analysis, and equally satisfactory as to purity to the certifying chemist, and are really fully as good, if not better, for the farmer. For lots of so-called pure dissolved bones are of an ammoniacal analysis so high that they could not possibly be produced from the best bones and acid alone. If this, then, be the case, why bother so much about purity? And why seek a guarantee which is of no consequence, and which does not admit of ready proof? Why not let the manure maker produce his soluble phosphate in the cheapest way he can? For does it not seem quite as unreasonable to demand that in any manure the soluble shall be wholly from pure bones, as it would be to require that sulphate ammonia should at least not be made from coals?

**Reverted Phosphates.**—But, in addition to this perplexity, there is the vexed question of reverted phosphates. Usually it is admitted that soluble phosphate is, on application to the soil, first precipitated, and then gradually redissolved by a rainfall slightly acidulated with carbonic anhydride. And if this be really the case, why should not reverted phosphate be every whit as good as the soluble, instead of ranking only with the ordinary insoluble portions of a manure? That the chemical change has taken place in one case before sale, and has in the other been deferred until after use, should not surely as at present involve any *very* substantial difference in the commercial value of the manure. There seems indeed but little doubt that the ordinary existing treatment of phosphates with acid is eventually but a round-about method of reproducing the original tricalcic or bone phosphate in a chemically fine state of division. And under such circumstances reverted phosphates are worthy of more considerate treatment than in this country they have hitherto received.

**Anomalies.**—It is certain, therefore, that much not only of the nomenclature, but of the usages of the chemical manure business, demand substantial revision. The manure trader has too long been dealt with in a rather unfair way, having been regarded not only as a sort of scientific expert to his customers, and as responsible for the analyses and condition of his products, but as liable to be called into account for the materials employed in his handicraft, as well as for the effects of his manufactures upon the crop. Surely this ought not so to be, for while it is highly desirable that, to the best of his ability, the manure maker should aid the farmer, there seems no equitable necessity that he should be his nurse. Wurtz, in his *History of Chemistry*, published about the time of the 1863 British Association meeting in Newcastle, declared chemistry to be a French science. But, had his thoughts momentarily rested on manurial chemistry in its commercial aspects, he would surely have made a special exception in its favour, for of all branches of science it seems the most painfully inexact. In the matter of analytical methods this is notorious. For even in so simple a question as manurial moisture, no existing method of analytical statement expresses the actual fact; while in the examination of phosphates and ammonia there still remains—after two decades of grumbling—the most trying discrepancies in different operators' results. What excuse also can decently be made for continuing to express and to value soluble phosphate not as soluble or monocalcic phosphate pure and simple, but by the quantity of tricalcic or bone phosphate consumed in its production? The thing seems absurd on the very face of it.

**Superphosphate Reaction.**—Then, again, from Ruffles' researches it seems as if the superphosphate reaction had been much misunderstood. That, in fact, the change taking place does not simply involve the conversion of two molecules

of lime into calcic sulphate, and of the remaining molecule into monocalcic phosphate, but that when in ordinary superphosphates the maximum sulphuric acid has been used to secure the desired chemical and mechanical result, there must of necessity be present a considerable amount of free phosphoric acid from the partial conversion into calcic sulphate of the third molecule of lime; and that there cannot be present any free sulphuric acid. In the case, however, of superphosphates prepared with sulphate ammonia, Ruffles also shows that the great bulk of the phosphoric acid present exists in the free state; that part of the sulphate ammonia is converted by this free acid into ammonium phosphate; and that of the rest, with the gypsum, a double salt of ammonia and lime is probably produced, which explains the hardening peculiarity of such superphosphates.

**Tyne Industry.**—About four years after the publication of Liebig's work previously referred to, or about the year 1844, Dr. Thos. Richardson began the manufacture of artificial manures at Blaydon. In connection with this venture he seems to have attempted the utilisation of the phosphates contained in the Lemington iron slag deposits, but his experiments in this direction were not apparently very popular with the farmers of that early period.

About the year 1848 Mr. Ramsay commenced manure making at Dunston; and in the year 1849 Mr. Sampson Langdale began the business at the Mushroom. By 1863 the number of manure works on the Tyne had increased to seven, making a total annual output of some 15,000 tons. But there were not until long afterwards any factories on the Wear or the Tees; while on our own river only two firms, viz., the Blaydon Manure and Alkali Company and the Monkton Manure Company were at that time makers of their own vitriol. The other firms were supplied with sulphuric acid by Mr. Christopher Myers, of Dunston, Messrs. Imcary and Co., Felling, the Jarrow Chemical Company, and the Walker Alkali Company.

The raw phosphatic materials employed were chiefly confined to bones, bone ash, spent charcoal, Cambridge, Bedford, and Suffolk coprolites, and the poorer guanos. These were allied with nitre cake, various waste nitrogenous materials (such as blood), and sulphate ammonia, the whole, excepting the guano and a portion of the bones and ash, being British products.

**Machinery.**—The bones were reduced about this time (1863) by means of serrated rolls, and the mineral phosphates by means of heavy edge runners. The materials were for the most part hand-treated in open tanks or troughs, being stirred with wood or iron rakes, but mechanical mixers were in process of adoption. Apparently, however, the knowledge brought to bear upon the dissolving operation was extremely crude, for the product was as a rule very pasty. One lot of Tyne manure seems to have been delivered at Dunbar in a state specially characteristic of the Scottish national dish—porridge—and to have required damming up to prevent its outflow from the store. Hence stove-drying had frequently to be practised (though it certainly could not have been good for the soluble), and absorption of excessive moisture by gypsum or tank waste was an every-day mode of treatment. Probably acid of too high strength was first employed under the erroneous impression that weaker acid would be less effective. And the reaction was rendered less complete by the imperfect reduction of the phosphatic materials, as a result of the employment of unsuitable grinding machinery, and of the absence of sifting appliances. The importance, too, of the presence of calcic carbonate was not then fully recognised—this being shown by one patent whose main object was its expulsion, by calcination of the raw phosphates before use. It is also remarkable, by way of contrast with the present exigencies of the trade that, owing to the high cost of sulphuric acid (about 5*l.* 10*s.* to 6*l.* per ton of "O.Y."), the great aim of the early traders was to spare it as far as they possibly could. Hence the standard of soluble in superphosphates was at first very low, being only some 16 per cent., rising to 20 per cent. somewhere about the year 1860. This is in marked contrast to the present ordinary standard of 29 to 31 per cent., and to the existing production of strengths, rising up to over 40 per cent.

*Statistics.*—In 1863 there was, as regards the Tyne, neither any import trade in raw phosphates or export trade in chemical manures, the entire business of that date being local and coastwise. The sole exception to this was bones, of which in that year 507 tons were imported from the Continent, and 811 tons from South America, making a total of 1,318 tons. But this figure, of course, by no means represented the entire consumption, which included a considerable proportion of British collected bones.

The whole of the Peruvian guano then used and sold in the North of England reached the Tyne coastwise, in transhipped cargoes, the first direct imports arriving in 1866. But as unfortunately neither phosphates nor guanos arriving coastwise were notified in the Tyne import lists before the Tyne Improvement Act of 1877, there are no obtainable figures to show the consumption of these in 1863. The total production of manure that year, however, appears to have been about 15,000 tons.

Nitrate soda was then little, if at all, used in the North of England as a direct manure, or as a source of nitrogen in phosphate manures. Its employment indeed for the latter purpose has never been very extensive, as, unlike sulphate ammonia, it cannot be passed through the mixer. The direct sale to farmers, however, of nitrate soda now forms a branch of the manure trade of growing importance, and probably not less than 2,000 tons are now annually disposed of in the North of England in this way.

The price of nitre has been extremely fluctuating. In 1863 its average would be about 15*l.* per ton, rising during the Chili-Peruvian war of 1880 to something like 20*l.*, and declining during the past 12 months to an average of under 9*l.*

*Sulphate Ammonia* making forms an important branch of the chemical manure industry, and one which in recent years has undergone considerable development. The total North of England make for 1863 is extremely difficult to estimate, but it was probably under 1,200 tons, of which some 370 tons were made by the Newcastle and Sunderland Gas Companies alone. In 1887 the two latter companies together produced nearly 1,600 tons, and the total district make in that year had nearly reached 3,000 tons, of which 300 tons were produced at Crook in the manufacture of coke. The rest was entirely obtained from gas liquors, and there is no local plant in present operation for ammoniacal recovery from other sources. Probably about one-half the entire district sulphate ammonia make goes to the Continent for use in beetroot culture. As with nitrate soda, the price of this commodity is an extremely fluctuating one. In 1863 the average would be about 15*l.* per ton (at which time the sulphate frequently contained injurious cyanides), but in 1889 it had fallen to some 11*l.* 15*s.* In the interval, however, it had temporarily risen to considerably over 20*l.*

*Peruvian Guano* has in latter years formed a declining trade, which has been partly due to unreasonably high prices, and increasing inferiority of quality. The total United Kingdom annual consumption will not at present probably exceed 30,000 to 35,000 tons, of which a very small proportion is sold in this locality.

In 1863 the chief sources of *manurial potash* were the German muriates, or the sulphates chiefly manufactured from them, for the British kelp trade had then become almost extinct. But more recently the Stassfurt kainit has chiefly been relied on, and of this a considerable quantity is supplied to farmers direct, as it has since its introduction been gradually assuming the position in agriculture formerly occupied by common salt. For manures, however, of high potash analysis, the German muriates are still extensively employed.

Since 1863 the North of England manure trade has made rapid forward strides. The number of works on or near the Tyne has now increased to eight, added to which there are also seven factories in the districts of the Wear and Tees. Six of these works possess vitriol plant. This list, however, does not include numerous bone grinding, offal, blood, fish manure, and sulphate ammonia works scattered over the Tyne, Wear, and Tees, *where phosphates are not treated with acid*. Neither does it include the half dozen works with a gross annual output of some 16,000 tons at Spittal (near

Berwick) and North Sunderland; nor the ten works in the Carlisle and Silloth districts, in which probably about 8,000 tons are annually made.

The total 1889 season's output from the above 15 factories on the Tyne, Wear, and Tees, may be approximately estimated at 40,000 tons, of which fully one-half is shipped to the continents of Europe and America.

And by way of contrast with 1863, practically the whole of this large output is manufactured from foreign materials, the 1887 phosphatic imports into the Tyne, for example, having been as follows:—

	Bones.	Mineral Phosphates.
	Tons.	Tons.
From Continent of Europe.....	492	6,803
From Continent of America, including West Indies.....	279	10,782
Coastwise (partly transhipped) ..	107	1,035
Total.....	878	18,680

But, as in 1863, an important portion of the total consumption of bones consists of those locally collected.

*Basic Slag.*—Within the past two or three years a new local industry has sprung up—in the utilisation of the basic slag from the works of the North-Eastern Steel Company (Limited) at Middlesbrough. The total annual output is about 40,000 tons, which is all contracted for by a German firm of chemical manure makers. The great bulk of it is used in Germany in the cultivation of sugar-beet, for which it appears to be a success. A small quantity, however, has been used in this country and in this district, but as the use has hardly yet passed beyond the experimental stage, little may at present be said as to results. Its phosphates are claimed to be more readily assimilable than the ordinary tricalcic phosphates ground to a like degree of fineness, and it is sold under the name of Thomas phosphate powder in a very fine state of mechanical division, 85 per cent. being guaranteed to pass through a sieve of 10,000 meshes per square inch. Phosphate equal to 17 per cent. phosphoric acid is also guaranteed.

It is boldly asserted to be even superior to ordinary superphosphates of like phosphoric acid test, but this seems on the face of it extremely problematical. For assuming the soluble phosphate in a superphosphate to be precipitated by contact with the soil, it can scarcely be supposed that a mineral phosphate in however intimate a state of mechanical division can favourably compare with as it were a phosphatic emulsion in a division chemically perfect, and consequently of maximum susceptibility to atmospheric influences.

*Present Mechanical Resources.*—In mechanical accessories the manure trade of the Tyne has undergone great recent development, appliances of the most advanced description being now in use. The old crushing rolls and edge runners which formerly sufficed for the comparatively rough treatment of the gravelly coprolites of early days, have now been abandoned for machinery able to cope successfully with the most refractory foreign phosphates, and to reduce them sufficiently for the necessary final treatment between heavy French burr millstones and sifting through revolving timpses of 2,000 to 3,000 meshes per square inch. The powerful Sturtevant mill of the Langdale Company, for instance, is equal to the reduction of over 300 tons phosphate rock per 24 hours. And generally a considerable amount of care and attention is now locally devoted to the comminution of phosphates as a means of attaining the highest dissolving efficiency. For as sulphuric acid is just about one-third its price in 1863, the great aim is to employ it as freely as is compatible with a good mechanical result.

There have also been substantial improvements in the mechanical treatment of bones, and the introduction of the high-speeded disintegrating class of machinery for the production of fine bone meals has tended to a large development of the bone meal trade.

The Noxious Vapours Acts of 1863 and 1874 did not concern the manure maker. But he was carefully provided for in the Act of 1881, and the North of England manufacturers generally were not slow to conform to the requirements of this. Condensing arrangements, therefore, of considerable efficiency are now almost universal. Their character is somewhat diverse, but the apparatus recently described by Mr. Macadam in a paper read before our Glasgow Section, and by Dr. A. B. Grifflits in his treatise on manures, is perhaps the most common and satisfactory to our Local Government inspectors. There are a number of sets (designed and erected by the writer) now at work in the North of England, and it is interesting to notice that of the seven chemical manufacturing districts throughout Great Britain and Ireland under Government inspection, the average escape of acid vapours from manure works in the North of England for the year 1888 was extremely satisfactory, and for the year previously was 50 per cent. less than in any of the other districts.

The manure trade is, in spite of general commercial activity, still struggling through a severe crisis in its history. Prices remain very discouraging, in spite of increased cost of raw material and increasing difficulties and troubles in the labour market; and yet until there be some substantial amelioration of the existing conditions of British farming, it seems almost hopeless to forecast any important or permanent improvement in a trade which is wholly dependent for its existence upon the successful pursuit of agriculture.

### SESSION 1890.

April 1st (Glasgow):—

Annual General Meeting of Section.

Mr. Jas. Hope. "The Estimation of Nickel and Cobalt."

Mr. R. R. Tatlock. "Note on the Fatty Acids of Olive and other Oils."

May 6th (Edinburgh):—

Dr. J. B. Readman. "The Manufacture of Phosphorus, Part II."

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

*Meeting held in the Societies' Rooms, 207, Bath Street, Glasgow, on Tuesday, 4th March 1890.*

MR. R. R. TATLOCK IN THE CHAIR.

## THE MANUFACTURE OF BLASTING-GELATINE.

BY GEORGE MACROBERTS, F.R.S.E., F.C.S., F.I.C.

BLASTING-GELATINE was patented by Mr. Nobel, the inventor of dynamite, in 1875. It is a compound of nitro-glycerin and nitro-cotton. When properly made it has a specific gravity of 1.5 to 1.55, and is a clear semi-transparent substance, slightly elastic, somewhat resembling

india-rubber in that respect. It usually consists of 92 to 93 per cent. of nitro-glycerin, and 7 to 8 per cent. of nitro-cotton. Blasting-gelatine is thus described by its inventor:—

"The object of this invention is to convert nitro-glycerin and analogous explosive liquids from their liquid state to a solid or semi-solid consistency. The liquid state is found to be dangerous in regard to storage, transport, and, in some cases, use; whereas the solid state is found to be highly conducive to safety and offers great facility for use, storage, and transport. In carrying out the invention, these liquid explosive substances are incorporated with another substance which is capable of gelatinising or thickening them, and for this purpose a substance is chosen which will detract little or nothing from their explosive power. Nitro-glycerin, which is the most powerful of liquid explosives, may be gelatinised by dissolving in it nitrated cellulose, such as the nitrated cotton which is known as collodion gun-cotton. The explosive compound becomes more and more gelatinous in proportion to the quantity of nitrated cellulose which is dissolved therein, and it forms, when 7 to 8 per cent. of the nitrated cellulose have been incorporated, a solid jelly, which is very safe and highly suitable for every purpose to which very powerful explosives can be applied. I do not, however, confine myself to that exact proportion, since it must be suited to the degree of hardness or consistency required for each special object in view."

The inventor then goes on to describe various mixtures with gelatinised nitro-glycerin which may be made to suit special purposes such, for example, as blasting, where a somewhat slow explosive is required, or for torpedo purposes, &c.

In the patent there is no mention made of any method of preparing the nitro-cotton required, nor of any special apparatus for mixing or incorporating the ingredients of the explosive; nor is there any mention made of apparatus for converting the finished explosive into cartridges. I soon found that special apparatus of some kind would have to be devised for incorporating the nitro-glycerin and the nitro-cotton, as these substances, when thrown together, gelatinise very slowly and very imperfectly. After numerous trials, I devised the apparatus shown in the drawing (Fig. 1), which is a rough sketch, full size, of a gelatine-making machine, such as I have used at Ardeer. The machine consists of a stout framework of wood, preferably teak, to avoid warping, with a copper or brass pan for holding the explosive ingredients, and of shafting. The horizontal shaft drives, by means of bevelled wheels, two vertical shafts to the bottom of which are fixed stirrers, which, when the machine is in motion, pass the ingredients in the pan from side to side and through each other, and in that way effect a thorough mixture in a very short time. The pan is double, the space between the outer and inner shells being filled with hot water during an operation. The outlet and inlet for the water are shown on the drawing. They may be arranged on opposite sides of the pan or on the same side, to suit the arrangements of the building in which the operation is carried on. During an operation, hot water flows continuously through the pan, otherwise a constant temperature, which is necessary, could not be kept up. The whole of the metal work of the machine is, as far as possible, of brass or gun-metal, and the greatest care is requisite in fitting up the machine, to guard against any contact between metal and metal where the explosive is. If the stirrers were to strike against each other, or against the pan, there would be danger of explosion. It will be noticed in the plan of the pan (Fig. 2) that there are four small wheels or rollers. The object of these is to facilitate the running in and out of the pan when a charge is put in or taken out. There is a kind of cradle or carriage, in which the pan is jammed during an operation. This cradle is capable of being elevated and lowered by means of screws. The screws are actuated by the lower horizontal shaft. When the pan is filled with an explosive mixture it is run in under the stirrers and, by means of the side screws, elevated until the stirrers are fully immersed in the mixture of nitro-glycerin and nitro-cotton. The pan is firmly held in that position during the stirring, and when the operation has proceeded until the explosive

mass is thoroughly gelatinised, the pan is again lowered by means of the screws, run out, and the contents removed. The capacity of the pan is such that about 2 cwt. of explosive can be treated at one operation. Each operation usually takes about an hour. The temperature of the water circulating round the pan is kept at 60° C. during the whole time. At that temperature the nitro-glycerin and nitro-cotton act readily on each other, and are resolved into a jelly. Without the hot water the gelatinisation would take place much more slowly and much more imperfectly. The temperature of the explosive in the pan is never allowed to get above 40° to 45° C. The temperature of the mass is taken from time to time, and should it show any tendency to go beyond the normal figure of 45° C. or thereabouts, means can be taken at once to cool down by cold water. The hot water is supplied from a barrel or tank standing near the gelatine-making machines. The water in the tank is heated by steam, and as the water is drawn away for the supply of the machines, it is renewed automatically, and no difficulty is found in regulating the temperature of the water in the tank to the constant figure of 60° C. At Ardeer I had eight machines in one house, ranged along the sides—four on each side. They are driven by belting from a shaft along the centre of the house, the shaft being actuated by a steam engine outside the building. As may be expected in machines intended to be used with a dangerous explosive, the motion is very slow, the stirrers revolving at from 20 to 30 revolutions per minute.

All factories for explosives in this country are regulated by orders from the Home Office Explosives Department, and only limited quantities are allowed in each building at one time. The buildings themselves are separated from each other by considerable distances and by the intervention of embankments, so that, in case of explosion in any building, the destruction may be confined to as small an area as possible. For that reason it is necessary to have the buildings in which the nitro-glycerin and nitro-cotton are made at considerable distances from those in which the gelatine is manufactured. The nitro-glycerin and the nitro-cotton and other ingredients that may be used in making the gelatine have, therefore, to be brought from considerable distances to the houses in which the gelatine is made.

In carrying out the making of blasting gelatine, therefore, the following routine is observed:—The nitro-cotton required is first brought from the nitro-cotton drying stove, weighed off in the quantity required for each charge, and put into gutta-percha or brass-lined wooden boxes capable of holding enough of nitro-glycerin and gun-cotton together for the charge of a gelatine-making machine. A number of these boxes, containing a quantity not exceeding the total allowed by the regulations, is then taken to the nitro-glycerin washing-house, and the proportion of nitro-glycerin required is weighed off and added to each box. The boxes are then conveyed to the gelatine-making house, and the contents transferred to the pans of the respective gelatine machines. As each pan is charged it is put under the stirrers, screwed up, and the machine started, and in the course of about an hour the gelatinisation is complete, and the pan ready to be cleaned out for another charge.

At first great difficulty was experienced in meeting the Government requirements for gelatine. Before a new explosive can be manufactured in this country, the permission of the Home Office has to be obtained, and in order to obtain that permission, samples of the explosive have to be submitted for trial, and from the behaviour of these samples when under chemical and physical treatment the Government regulations for the manufacture and testing of the explosive are deduced. The Home Office had prescribed that in the case of blasting-gelatine offered for sale the explosive was to be free from every species of exudation, and that a sample taken from a box of the explosive as offered for sale should, when exposed to freezing and thawing three times successively, show no signs of exudation; and that a 50 grms. sample exposed in a test tube for 10 minutes to a temperature of 160° F. or 71° C. should show only very faint action on iodised and starched test paper. The conditions required by these tests were found, at first, to be difficult to fulfil, and fault was found by the Government inspectors with certain samples which failed to comply with the prescribed tests.

After careful investigation I found that the nitro-cotton was almost entirely to blame for the failure to pass the tests, and I then set about to discover a method of making nitro-cotton which would enable the finished product to fully comply with the Government requirements. The kind of nitro-cotton for making blasting-gelatine is a mixture of bi-nitro- and mono-nitro-cellulose—not the ordinary tri-nitro-cellulose or real gun-cotton. By careful attention to the proportions and mixing of the acids for the nitration of the cotton, and to the temperature at which the nitration was effected, and by thorough washing and boiling of the nitro-cotton, I succeeded in producing an article of uniform quality which made an invariably good gelatine. The nitro-cotton requires to be finely divided and well dried. The dividing I effected by means of a paper pulping machine, and the final washing by boiling and steaming the nitro-cotton, sometimes for days. I effected the drying by means of hot air. The nitro-cotton is placed in a lightly constructed stove in which there are frames with trays on which the nitro-cotton is placed, and a current of hot air is driven through the stove, the temperature being kept as nearly as possible between 100° and 110° F. It is not allowed to exceed the latter limit. In the earlier made gelatine it was thought unnecessary to go beyond centrifugal drying for the nitro-cotton. By means of a centrifugal machine the nitro-cotton can be dried down to 25 per cent. of water, and that proportion of water, in a substance which formed only 8 per cent. of the whole mixture, appeared to be a trifle, but experience soon showed that the presence of water tended to make the nitro-glycerin exude from the finished gelatine. The gelatine now made at Ardeer with thoroughly dried nitro-cotton, prepared as described above, complies fully with all the Government tests, and is found to keep for any length of time without showing signs of exudation. Her Majesty's Government bought, about three or four years ago, 30 tons of blasting-gelatine for the War Department. It is kept in magazines under water, and up till now it has shown no signs of change. When 3 or 4 per cent. only of nitro-cotton is incorporated with nitro-glycerin, the result is a thin liquid jelly which is of itself unsuitable for making into cartridges, but such a jelly is well suited for mixing with charcoal and nitrate of potash, or with wood meal, nitrate of ammonia and charcoal, so as to form other varieties of blasting-gelatine. Blasting-gelatine made with those ingredients is sold under various names, such as gelatine-dynamite, gelignite, &c. By using a small percentage of the thin gelatine and a larger percentage of the nitrate of potash and charcoal, or wood meal mixture, a cheap and useful variety of gelatine is formed, suitable for many kinds of blasting. Pure blasting-gelatine, consisting of 7 per cent. nitro-cotton and 93 per cent. nitro-glycerin, is the strongest. The varieties formed with other ingredients have for their object the cheapening of the explosive as well as its adaptation to particular kinds of blasting.

Of all the nitro-glycerin explosives, blasting-gelatine is the strongest. If the energy of dynamite be represented by 100, that of blasting-gelatine will be 150. Nitro-glycerin itself shows less energy than blasting-gelatine.

It is specially suited for blasting in water, as its explosive properties are in no way affected by water, and it may remain any length of time under water without change. On the other hand, dynamite under such conditions loses its nitro-glycerin, and becomes in fact resolved into its ingredients; so that to blast with it effectively under water, the cartridges require to be protected by some waterproof material.

Blasting-gelatine in all its varieties is exploded by means of a detonator, as is the case with dynamite, but detonators for exploding gelatine require to be much stronger than those for dynamite.

Blasting-gelatine made as described above has to be converted into cartridges to suit the various mining operations. The machine I devised for that purpose is a kind of sausage-making machine, of which a rough sketch is here shown (Fig. 3). The whole machine is made of brass or gun-metal. It consists of a case with a shaft and screw. The revolution of the shaft causes the thread of the screw to push forward the gelatine introduced by the square opening at the top, to the nozzle, whence the gelatine issues in a

# PLANT FOR THE MANUFACTURE OF BLASTING GELATINE.

Scale of One Inch to the Foot.

continuous rope or cord. The nozzles are of different sizes to suit the various sizes of cartridges required. It is an essential principle of these machines that no metallic contact shall be allowed inside. When the machine is in operation the screw revolves quite clear of the case, and the thrust of the machine is taken up by the collar shown against the second plunger-block. If by any chance the screw and shaft should be thrust back, there is a leather washer against which it would rub, so that there would be no danger. The way in which the machine operates is as follows:—

The girl who works the machine lifts a lump of gelatine and pushes it into the opening with her left hand, at the same time turning the handle with her right hand. The threads of the screw push the gelatine rapidly forward to the nozzle, and in a few revolutions the whole of the gelatine is converted into a long rope. When the girl has expelled a yard of two of this rope from the machine, she seizes it with her left hand, and with a wooden knife in her right quickly cuts it into cartridge lengths, which are taken up by other girls and rolled in cartridge paper. Each cartridge but contains four girls, and one machine worked by one girl turns out sufficient cartridges to keep the whole four busily employed. Each cartridge-making machine can form into cartridges from 5 to 10 cwt. a day, depending on the diameter of the cartridges.

It is wonderful to observe the great dexterity the cartridge girls attain in working these small machines. The cartridges, although cut into lengths by the eye and folded without any measure as to length or diameter, are very nearly uniform in size. You will notice in the section of the cartridge-making machine case that there are lines running from the back converging towards the nozzle. These lines represent grooves in the casing like the rifling of a gun. Without these grooves the efficiency of the machine would be very much reduced or altogether destroyed. The grooves prevent the gelatine from revolving with the screw and hold it in position, while the screw pushes it forward. Each machine has an assortment of nozzles which can be taken off and put on in a few seconds, so that it is adapted for cartridges of any diameter.

Regarding the safety of the operations described in the foregoing, it is satisfactory to state that from the commencement of the manufacture until now there has been no accident in the blasting-gelatine department at Ardeer; so that it may be fairly inferred that the principle on which the machines are constructed and worked is a thoroughly safe one.

As the patent for blasting-gelatine was taken out in 1875, and as its duration was only for 14 years, it expired last year. The manufacture of blasting-gelatine in this country is confined to one firm, that of Nobel's Explosives Company, and is likely to continue in their hands alone. Although anyone is now at liberty to commence the manufacture of nitro-glycerin preparations, so far as patents are concerned, yet the manufacture is surrounded with so many difficulties, the difficulty of obtaining a suitable site, difficulties with the local authorities, difficulties with the Home Office, and last though not least the difficulty of obtaining suitable technical management, that it is not likely Nobel's Company will find their monopoly disturbed for a long time to come.

I have thus briefly described the manufacture of blasting-gelatine as carried on by me at Ardeer, and I have avoided touching on many interesting points connected with the manufacture, because of the time that would be taken up by such references. There are, connected with the manufacture of blasting-gelatine and nitro-cotton, many interesting points which would require for their discussion much more time than is allotted for a single paper.

#### DISCUSSION.

Mr. STANFORD said he was sure they would all regret very much that Mr. MacRoberts was unable to be present to read the paper himself. Regarding the monopoly in the manufacture possessed by Nobel's Explosives Company, he quite agreed with what was said in the latter part of the paper, that it was not likely to be disturbed for some time. The

solution of the collodion cotton by the nitro-glycerin was a great discovery because it enabled them to employ the nitro-glycerin in a partially solid form. He used to think the manufacture of this blasting-gelatine a terrible thing for any chemist to undertake until he had the pleasure, with some others, of going over the works at Ardeer, when he was struck with the ingenious manner in which the various processes were carried out, which showed that where there was great care and thorough knowledge there was no danger.

Mr. KATER said that the reason why collodion cotton and not gun-cotton was used in the manufacture of blasting-gelatine was that gun-cotton is insoluble in nitro-glycerin.

The CHAIRMAN said that he thought that the invention and the devising of the apparatus for producing this most perfect of all explosives—blasting-gelatine—was one of the most striking examples they could find of what often happens with regard to inventions, viz.:—that they lay dormant for a long period without any possibility of applying them, until some one appeared who had the skill or the genius to devise and work out methods and machinery for their application as practicable and profitable commercial processes. Previous to 1867 nitro-glycerin had been employed in America, but its use became a dead letter in this country until Mr. Nobel patented methods for absorbing the liquid nitro-glycerin into porous substances, which resulted in the preparation of dynamite, containing 75 per cent. of nitro-glycerin and 25 per cent. of kieselguhr. But even this extraordinary product had its disadvantages, for when brought into contact with water the nitro-glycerin exuded. This was obviated, however, by the discovery of blasting-gelatine, a more perfect explosive than nitro-glycerin itself.

#### THE MACARTHUR-FORREST PROCESS OF GOLD EXTRACTION.

By J. S. MACARTHUR.

In order to understand the present systems of gold extraction to properly appreciate the work already done, and to gauge the difficulties to be surmounted, it is necessary for us to look back and trace the connexion between the known forms of gold as found in nature and the methods used to separate it from its base environments.

In the earliest ages gold would naturally only be found in nuggets and grains (our word carat is derived from a Persian word meaning a grain) which required no means of separation beyond picking up—happy age when gold had only to be picked up!

From grains the ancients would come down to gold dust, and this was no doubt separated from the sand or earthy matter with which it was associated, by the skilful use of air currents which were caused to blow away the sand, leaving the precious metallic dust. This method is still practised in Arabia and the East. Wherever water was plentiful it was found that it did the required separation better and more economically than air, a method of separation which has been and still is in use everywhere all over the world. The prospector, digger, explorer, and even the tourist nowadays provides himself a "pan" in which to wash a sample of "dirt" at the nearest stream. From the pan comes the "cradle," "long tom," and the innumerable mechanical arrangements for the separation of gold from earthy matters. Up to this point we have only mechanical means of separation which depend on the high specific gravity of gold compared with sand, clay, &c., but at this stage in the evolution of gold extraction we find the first move made towards a chemical method. When there was a lot of rich dirt in his pan the digger found it very difficult to wash away the last of the sand without losing a large proportion of the finely divided gold, so he hit on the expedient of pouring in a little mercury, which formed a heavy, massive, though fluid alloy with the gold, making the separation of the last portions of the light

granular sand a very easy matter. This plan is still in world-wide use alike by the solitary digger who lives in a lonely cañon and by the well-organised company that "hydraulics" 1,000 tons of "pay dirt" per day.

Let us now look at the present state of the gold industry. Let us imagine a digger who has exhausted all the gravel and pay-dirt in the cañon or gully; he travels up the gully looking to right hand and to left for traces of the precious metal; occasionally he finds a piece of gold-bearing rock and is led on and on till he finds the source of these auriferous stones to be a reef. Now begins gold-mining proper. A shaft is sunk on the reef or a tunnel driven into it and great masses of rock are brought to the surface, and naturally the miner is led to imitate nature by crushing this rock to a fine sand and then he modifies the treatment formerly given to alluvial deposits to adapt it to the new circumstances. The ore, immediately on being crushed to powder (which is generally done by huge gravitation stamps), is carried over an amalgamated copper plate by a stream of water. In passing over the amalgamated plate the gold is caught by the mercury, while the sand, now called tailings, is washed off. The gold is recovered by scraping the amalgam off the copper plate at stated intervals, generally once a month, when by distillation the mercury is recovered as well as the gold separated. If all the gold the ore contained existed in the heavy metallic form the recovery by this method would be complete and the loss nil; but the tailings are frequently found to contain a little gold, and on close examination particles of pyrites and sulphides of the various base metals are found diffused through the mass. When these metalliferous particles are separated from the mass of tailings, it is found that they principally contain the gold, so that it is now usual in practice to pass the tailings through some form of concentrating machinery, of which the well-known Frue-vanner is a good example, whereby the pyrites and other sulphides are retained in virtue of their higher specific gravity and the sand washed away. The rich proportion now called "concentrates" may contain up to 20 oz. of gold per ton, though four or five ounces is much nearer the average figure.

If the concentrates are examined closely, even microscopically, no free gold can be distinguished, and if they be treated with mercury they will yield to it little or none of their gold contents. Sometimes a considerable portion of gold may be got from them by a long continued grinding in cast-iron pans in presence of mercury; this grinding seems to force the sulphur and base metals as well as the gold into combination with the mercury, so that the bullion got from the amalgam often contains over 95 per cent. of copper, lead, and other base metals, while there is a corresponding loss of mercury which is carried away partly as sulphide and partly in a "floured state"—the flouring is caused by the small globules of mercury being coated with a film of sulphide of mercury which prevents the particles coalescing. Thus there is a double loss: chemical, by the formation of sulphide of mercury, and mechanical, by flouring. This loss is so well known that concentrates are only treated by this form of amalgamation in localities where nature forbids any more elaborate process. Sometimes the amount of loss may be lessened by roasting the concentrates before amalgamation, but this is by no means a perfect remedy, as the roasting removes only volatile constituents of the concentrates, principally sulphur, while the base metals, lead, zinc, &c., are left in the form of oxide to oxidise and waste their equivalent of mercury. Attempts have also been made to decrease the loss of mercury and increase the yield of gold by adding to the contents of the pan all sorts of chemicals to "doctor" the "sickened"—that is, floured mercury. These chemicals are generally mixtures of sulphate of iron, sulphate of copper, salt, lime, soda, &c. This kind of "doctoring" may be effective in some cases, but it is seldom practised with intelligence. Where the percentage of concentrates is limited, and where there are a number of mines, it is common for some enterprising man to set up a smelting or chlorination work which is made large enough to deal with the concentrates of the district. I will not take time to describe the various processes of

smelting, nor could it be done at any evening sederunt, but we may bear in mind that all smelting processes end in alloying the gold with lead, and cupelling in the usual way with which we are all familiar. Because of the obvious impracticability of smelting, requiring well-built brick furnaces, coal, fluxes, &c., at the typical gold mine high up on the mountain range, possibly near or beyond the timber line, chlorination is much more commonly practised and consequently merits a full description. In giving this description, I will confine myself chiefly to the old standard Plattner process as I have seen it practised in California, where timber is abundant and cheap.

The first and essential operation prior to chlorination proper is roasting. It is obvious that a mixture of sulphides and arsenides of iron, copper, lead, zinc, and metals generally will absorb an almost unlimited amount of chlorine, so that the small proportion of gold present would fare badly in a general scramble of the molecules for chlorine. That the metals may have the least opportunity to combine with chlorine, the sulphur is expelled, and their affinities satisfied as far as possible with oxygen by roasting. The roasting is generally done in a large reverberatory furnace, that has no very noteworthy feature in its construction. The concentrates are charged into the furnace at the cold end, heated very gradually, continually stirred and slowly worked forward into the hottest part, care being taken to admit air freely during the whole operation. Where chlorination is practised on the most extensive scale this roasting generally takes about 24 hours, and consumes from a minimum of half a cord to a cord of wood per ton roasted. (A cord of wood gives about as much heat as a ton of coal.) It is a common saying that the success of chlorination depends more on the furnaceman than on the chlorinator, and on looking into hard chemical facts we find that this is really the case, for if only one-half per cent. of iron were left unoxidised it would absorb nearly 1 per cent. of chlorine, equal to about 3 per cent. of bleaching-powder, and all this before the gold gets a single molecule of chlorine. Towards the end of the roasting, and about 15 or 30 minutes before the ore is discharged from the furnace, it is usual to stir in a small proportion of common salt. The object of this is to satisfy with chlorine as far as possible copper, zinc, and other metals whose oxides have a tendency to form chlorides when they get chlorine presented to them in the free state. This chloridising device is, however, only partially effective, as the chlorides formed are apt to be immediately decomposed under the influence of hot air, and in the case of lead the oxide or sulphate will not combine with chlorine in the furnace, but combines with it readily when offered moist and at the ordinary atmosphere temperature. The roasted and oxidised ore is now sprinkled with water to make it slightly moist, and is then charged into a wooden vat having a perforated false bottom. The chlorine, generated at an outside source, is led in between the true and false bottom, and gradually permeates upwards through the mass of the porous ore. The small amount of water held by the ore then becomes a saturated solution of chlorine, which gradually acts on the gold, so that in the course of one or two days it may be washed out as the soluble chloride by a further amount of water. This weak solution of chloride of gold is run into a tank, a solution of ferrous sulphate added, the precipitate of gold allowed to settle for 48 hours if possible, and the supernatant solution allowed to flow off. When sufficient gold precipitate has accumulated, it is collected and run into bars. Besides the Plattner form of chlorination which I have described, there are others which vary from Plattner and among themselves in the manner of application of the chlorine—most of them using revolving barrels instead of open vats for the chlorination proper.

The best known of these are:—

The Mear's process, where chlorine is used under its own gaseous pressure.

The Newbery-Vautin, where air pressure is used.

The Pollok, recently described before this Section of the Society, where hydraulic pressure is used, and

The Thies, where the chlorination is done in a barrel without any pressure, as described in this Journal, 1889, 895.

Let us now return to the mine. The deeper we sink down into the reef we find that while the richness of the ore may remain constant, the proportion of free gold, that is amalgamable gold, becomes smaller and smaller, while the proportion of gold-bearing sulphides becomes greater and greater till we come to the water level, where it often happens that the free gold leaves entirely and becomes wholly refractory, that is, non-amalgamable. The water level is generally regarded as the point where atmospheric and weather influences cease, and that down to that point the rain water has penetrated and gradually washed away the oxidisable base metals, leaving the inert gold in the crevices of the equally inert quartz, whereas the ore found below the water level, not having been subjected to oxidising influences, retains all its metals untouched and unchanged.

An interesting problem now presents itself:—An ore consisting of a complex mixture of silica and the various compounds of iron, copper, lead, zinc, antimony, arsenic, and sulphur (for convenience I will include all these compounds under the general term sulphides) and gold in the proportion of 10,000 parts of silica and sulphides to one part of gold, is very much richer than the average auriferous ore, and the question is how can we best separate the one from the ten thousand. Under favourable circumstances the gold and the useful metals may be recovered by smelting, but these favourable circumstances, which are proximity of the gold mine to coal, clay, limestone, and other fluxes, are quite exceptional, as auriferous reefs are generally found in primary formations. As before implied, chlorination is frequently inapplicable—no attempt is ever made to chlorinate gold ores containing an appreciable quantity of lead—and where applicable is always troublesome and never cheap. When this question presented itself to the Drs. Forrest and myself, we tried to find some solvent which, unlike chlorine and mercury, would have a stronger affinity for gold than for sulphides. Acting on this principle we drew out a list of all probable or possible solvents fulfilling this condition. This list included cyanides, and we found that these salts solved the problem.

Our experiments were conducted first on a small scale, and on ores of all kinds and from all mines in all parts of the world. The result of these small trials was so satisfactory that we gradually worked from less to more, and in no long time larger quantities were worked, and now the process is in, or on the eve of being put in operation in all quarters of the globe. I have now much pleasure in describing the method of working most generally applicable. The ore is ground to about the fineness of sea sand. If instead of ore we are working tailings from the amalgamation process, these are generally not re-ground, but treated as delivered. The finely divided material is mixed with a solution of a cyanide, say cyanide of potassium, containing on an average 0.4 per cent. of cyanogen as the cyanide of potassium or other alkali or alkaline earth. The ore and solution are stirred together for about six hours, more or less, this being the average time required to dissolve the gold: in practice the time required is determined by direct experiment. When the gold is known to be dissolved, the pulp is discharged into an ordinary filtering tank, where the filtration may, if necessary, be assisted by suction, and where the ore is washed by water or by the waste cyanide solution from a previous operation. The ore, after treatment with cyanide solution, is unchanged to the eye, as almost nothing but the imperceptible proportion of gold present has been removed. The gold now being in solution, the next object is to get it precipitated, and here we encounter a serious difficulty. Gold and cyanogen have such a strong mutual affinity, that it is difficult to get any substance that will separate them. The gold cannot be precipitated by any ordinary method, such as the use of ferrous sulphate or oxalic acid; even sulphuretted hydrogen and sulphide of sodium will not precipitate gold from its cyanide solution, though they precipitate silver. On referring to books on electro-gilding, we got no assistance, as the invariable method given for the recovery of gold from cyanide solutions was, evaporate to dryness and fuse the residue. We had noticed, however, by experiment, that zinc precipitated gold very feebly, and tried this in the same way that copper is precipitated from its ordinary solutions by scrap iron, but

scrap zinc had no effect; then granulated zinc was tried, with a most imperfect and disappointing result; then heating in presence of scrap and granulated zinc, but this had only the effect of forming urea, and assisting the precipitation very little indeed. Further, we tried zinc dust, but still there was no success; finally we prepared some zinc in a form like sawdust, porous and with a large surface of bright metal. On allowing the cyanide of gold solution to trickle through a mass of the zinc, we found that it trickled out gold-free, and, better still, we found that the action became more vigorous and pronounced after a portion of the gold had been precipitated on it, doubtless as gold and zinc formed together a more powerful electro-chemical precipitant than zinc by itself. An arrangement of a porous mass of zinc like a sponge formed a chemical filter, which at once precipitated and collected the precious metal; indeed, so like an ordinary water purifying device was this zinc filter, that many non-technical visitors formed and held tenaciously to the idea that the gold was in suspension in the cyanide solution, and the zinc was used merely because of its durability. Improvements in detail were made in the direction of increasing the surface and decreasing the weight of the zinc; till now we have it in threads, 1 lb. of which occupies about two gallons measure. The zinc in this form is possessed of enormous chemical activity, of which the strongest and most direct evidence is the fact that it burns in the air like thin shavings of wood. When the gold has been deposited, it is necessary to separate it from the excess of zinc present. The filiform structure of the zinc, and the exceedingly fine powder, as which the gold is deposited, render this an easy matter. The filiform mass of zinc with gold powder adhering is vigorously shaken in water, when the gold falls off, and the fibrous particles of the zinc may be collected in a sieve. The gold settles easily, is collected, and fused directly into bullion.

Having now described the chief points in the process from the technical standpoint, let us look at the purely chemical aspect it presents. Reference has already been made to the fact that a cyanide solution acts on the gold in ores in preference to the sulphides of base metals with which it may be combined or associated; this selective action is the keystone of the whole process. It is known that metallic gold is dissolved by a cyanide; it is also known that sulphides of copper, zinc, and iron artificially prepared are readily acted on by a cyanide solution; but we found a very different state of affairs in treating ores where these or similar compounds exist prepared by the hand of nature herself. Nature seems to render the base metallic compounds insoluble, while the gold combined with or contained in them is more easily acted on than the metal itself. This at once raises the question—how does gold exist in base refractory ores, is it combined or free? This question I admit I cannot answer satisfactorily to myself. Judging from theoretical considerations only, I think gold should exist almost invariably in the free state, for if we assume that sulphides, pyrites, &c., were formed by deposition from aqueous solution, the gold would be deposited in the metallic state. This may be shown by dropping some powdered pyrites into a solution of chloride of gold, when gold will be precipitated as metal; on the other hand let us assume that the pyritous formations carrying gold were formed by igneous agency in this case the gold ought to be metallic too, because any sulphide of gold already existing would be decomposed by the high temperature, and of course sulphide of gold cannot be formed at a high temperature. It is true that sulphide of gold may combine with an alkaline sulphide and resist decomposition by heat, but such a combination as a matter of fact does not occur in nature. Telluride of gold, and I think antimonide of gold are not decomposed by heat, but they occur in small quantities only and do not affect the general argument. In spite of these theoretical considerations, however, we have strong evidence to show that gold exists in several different states of combination or of molecular structure. Let me give one case in illustration. A sample of tailings from the ordinary process of stamping and amalgamation was received, and I think it may safely be assumed that the mercury had extracted some gold from the ore which produced these tailings. We treated the finely ground tailings by alkaline solution of bromine which

extracted a considerable portion of gold, and the bromine treatment was repeated time after time till it ceased to extract gold; then it was treated with a hot solution of ferric bromide which yielded a further quantity of gold. This treatment was repeated time after time till it ceased to extract gold, and finally the residue of tailings was smelted and a still further quantity of gold produced. As this ore yielded its gold in stages to the four different processes of amalgamation, treatment with bromine, treatment with ferric bromide and smelting, we infer that the gold existed in four different states, mechanical or chemical. Notwithstanding the complex nature of these tailings which consisted of all sorts of sulphides with the four-fold gold, the cyanide acted on it, almost perfectly extracting 93 per cent. of the precious metal, whilst the highest extraction by any of the bromination methods was about 40 to 50 per cent. The cyanogen seemed to have an affinity for gold and a power of penetration so much stronger than mercury or bromine, that it broke through barriers impregnable to them and captured the gold.

Elsner has stated that metallic gold dissolves in cyanide of potassium only in presence of oxygen. Not having seen the original account of Elsner's researches, I am not in a position to criticise his experiments, but I never could find that the presence of oxygen was necessary either to dissolve gold by itself or from ores by cyanide. If a piece of gold be immersed in cyanide solution so that air to act on it would have to penetrate 2 in. or 3 in. of the solution, the gold will dissolve in its usual slow and steady fashion. The equation shows that either oxygen must be absorbed or hydrogen evolved. I have seen no evidence of the former, and can adduce no proof of the latter; but I think the latter the more probable, because I cannot conceive oxygen penetrating even a film of cyanide solution without at once oxidising the cyanide to cyanate, whereas in the other case, as suggested to me by my friend Mr. Ellis, the nascent hydrogen may be at once seized by the excess of cyanide present and ammoniacal compounds formed. However, we do not concern ourselves much with the reactions of pure gold, but as a matter of fact we cannot find that oxygen plays any part in the cyanide extraction of gold from ores. We have treated an ore with cyanide with free access of air, and then a parallel experiment was done with boiled water, the bottle filled to the stopper with solution and ore, and the stopper sealed. The extraction was the same in both cases.

We have so far only considered ores which are refractory from chemical as well as mechanical causes, but ores are frequently found in which the gold is refractory from a purely mechanical cause, which is the extremely fine division of the gold. The cyanide process is quite as applicable to this class of ore as to any other. These ores are generally spongy and absorbent, and this we find enables us to dispense with stirring the ore and cyanide solution together, the same end being accomplished by allowing the cyanide solution to percolate slowly through the mass—a clear saving in power.

The advantages claimed for the cyanide process over smelting and chlorination are—as compared with smelting, it requires no furnaces and no coal, and no fluxes, and thus may be used successfully in remote situations where smelting is utterly impossible. As compared with chlorination, the cyanide process involves no roasting, therefore no furnaces and no fuel. Moreover, by the cyanide process, ores containing lead, zinc, or earthy carbonates which cannot be worked to profit by chlorination, may be as easily and profitably treated as any other. For chlorination, about 7 per cent. of the weight of the ore to be treated often has to be carried to the ore in the form of bleaching-powder, say  $1\frac{1}{2}$  per cent., bisulphate of soda 2 per cent., and sulphate of iron,  $2\frac{1}{2}$  per cent., with packing, say, of 1 per cent., whereas about 1 per cent. of the ore to be treated will cover the weight of the necessary cyanide, zinc, and packing. Thus, by chlorination, one ton of chemicals will treat only about 14 tons, whereas by the cyanide method one ton will treat 100 tons.

Moreover, chlorination does not extract any silver, but by the cyanide method the most of the silver—invariably

associated with gold in ores—is extracted along with the latter metal at the same operation. For the sake of simplicity I have not named silver in the body of this paper, but the remarks made in reference to gold generally apply to the silver associated with it.

From what I have seen of gold mines and gold mining in the Sierra Nevada, in the Rocky Mountains, in the Southern States of America, in Nova Scotia, from the many kinds of ore I have seen from all parts of the world, and from what I know of the selective and energetic action of cyanides, I confidently predict that cyanide of potassium, hitherto used only to polish amalgamated plates, will take a front rank as chief agent in gold extraction.

#### DISCUSSION.

Mr. BUCHANAN said that Mr. MacArthur in his able paper had pointed out at some length the great contrast between the weight of chemicals used in the chlorination and cyanide processes. He admitted that the former required a greater weight of reagents than the latter, but the author should also state the relative prices of these chemicals, the cost of the chemicals for chlorination being, he believed, but a fraction of the cost of cyanide. What was the cost of cyanide and other reagents used per ton? He would also be obliged if Mr. MacArthur would give some information as to the mode of, and time taken for filtration.

Mr. POLLOK remarked that he had experienced no difficulty in chlorinating ores containing lead and earthy carbonates up to 5 per cent.; larger quantities he had not met with. Such ores had also been successfully chlorinated by other processes in the United States.

Mr. RODGER asked how Mr. MacArthur proposed to produce the cyanide in sufficient quantities to cyanise the ores, and also how he produced the zinc in the gossamer-like form, such as the sample he had shown.

Mr. FAWSITT remarked that it seemed to him the price of cyanides would rise very much if this process came into operation. He would like to ask if Mr. MacArthur recovered his cyanide, and if so, how, or if it was lost. It was a most important point if it could be recovered.

The CHAIRMAN asked if, in treating the tailings from an amalgamation process, would any mercury left behind affect the cyanide? How did the process behave with such ores as contained a large proportion of silver in the form of sulphide? The amount of gold extracted was only one point, and must be taken in conjunction with other circumstances. To say that a certain percentage of gold was extracted from an ore did not convey an accurate idea of the value of the process, as its success, or otherwise, depended on a number of conditions. There could be no doubt as to the extreme simplicity, efficiency, and cheapness of cyanides for dissolving gold and silver, but he supposed this process, like most others, would not be perfect in every little particular, nor could it, any more than any other, give precisely the same uniformly successful results on every class of ore.

Mr. MACARTHUR, in reply to Mr. Buchanan, said that in his paper he did his best to be accurate in comparing costs, but the actual costs of chemicals could not properly be compared in Glasgow where there were no gold mines; the proper estimate and comparison must be made on the spot where the chemicals were to be used. The best answer to the question of costs was to give the latest return from Australia, which showed that 100 tons had been worked by the MacArthur-Forrest process at a total cost of 25s. per ton. Of this total amount 17s. 6d. was the price of the cyanide used, including all charges of transit and a high duty. The average time for a filtration washing was about two hours.

In regard to what Mr. Pollok said, all he could say in reply was that he did his best to be accurate in giving the weights of chemicals necessary for chlorination, and had got the figures for bleaching-powder and bisulphate of soda from a pamphlet issued by the Pollok Company; but as the amount of ferrous sulphate was not given it was calculated

as the exact equivalent of the bleaching-powder. About ores containing lime he must congratulate Mr. Pollok on his successful modification in roasting by which this difficulty, which Mr. Pollok too had recognised, had been overcome. Regarding lead, he had found that sulphate of lead absorbed free chlorine readily, and that oxide of lead actually precipitated gold from its solution as chloride.

In reply to Mr. Rodger, he said that the cyanide used in this process was prepared in the usual manner from ferro-cyanide of potassium. The zinc shown was prepared by mounting discs of sheet zinc in a turning lathe and taking off shavings by a turning tool.

In reply to Mr. Fawsitt, he thought that a larger demand was more likely to lower than to raise the price of cyanide, and though they had recovery processes for the cyanide they had not been put in practice, and in estimating costs nothing had been allowed for the recovery of cyanide.

Replying to the Chairman's questions he said that the presence of mercury in tailings presented no obstacle whatever to the action of the cyanide, and though silver as sulphide was not very easily dissolved in some cases, usually it could be extracted. A 20-ton lot might be quoted, where the silver (as sulphide) and the gold were equally well extracted, though there was an enormous excess of silver over gold. In fact the cyanide had an almost human intelligence in its preference for gold.

#### DISCUSSION ON MR. FAWSITT'S PAPER "ON THE FIXATION OF NITROGEN."

(This Journal, 1890, 30.)

MR. HENDERSON said that, contrary to a statement in Mr. Fawsitt's valuable paper, it was usually stated in textbooks that metallic derivatives of acetylene,  $C_2HK$  and  $C_2K_2$ , could be obtained by passing acetylene over melted potassium, and he thought that a similar calcium derivative,  $C_2Ca$ , had also been prepared. He was doubtful also of the probability of the formation of  $K_2C_2O_2$ , seeing that potassium was said to decompose acetylene at high temperatures, with separation of carbon, while  $K_2C_2O_2$  was said to be obtained by the action of potassium on acetylene at about  $80^\circ C$ . He should be glad of further information on these points.

MR. STANFORD said he thought that the paper might be looked upon as a concise résumé of what was known upon the subject of the formation of cyanide on a large scale. Regarding the process mentioned by Mr. Fawsitt of the passing of ammonia over charcoal highly heated, he would like to ask if the decomposition was at all complete, and also at what temperature the reaction took place.

The CHAIRMAN said that, considering the great importance of this subject, it seemed strange that so little work of a practical character had been done with the object of fixing nitrogen in some useful form. This might be partly accounted for, however, by the failure of the extensive trials made by Bramwell and Hughes some 40 years ago. At first these experiments promised very well, both on the small and larger scale, but when the process was tried in manufacturing it was found that the loss was so great and the expenses so heavy that it had to be abandoned. There had been, he thought, a good deal of misapprehension with regard to the reactions which were said to have taken place in the experiments conducted by Bunsen and Playfair with the object of determining the presence of cyanogen in a particular zone of the blast furnace. He had not understood that cyanogen had ever been produced by the action of nitrogen upon carbon. It was all very well to withdraw gases from a furnace in operation and test these for cyanogen, which might have required a base for its fixation. Undoubtedly it would be found, if the gases were taken off

at the proper point, but it was necessary to insure not only the absence of bases, but also that the cyanogen even then found in the free state had not been fixed by the metal of an alkali or of an alkaline earth. Another question was whether cyanide of ammonium had ever been produced by passing ammonia over charcoal at any temperature whatever. He did not believe that had ever been done, although it was stated by Kuhlmann, about 50 years ago, to have taken place. If ammonia could be converted into cyanide of ammonia so easily, then the problem, it seemed to him, was already solved; but if so, it was inexplicable that so simple and so very desirable a reaction had never found application in practice. He was not stating his own opinion so much as that of others who had paid much attention to the subject practically, when he said he thought that was the crucial point in the question.

MR. PLAYFAIR said that in the production of cyanides the difficulty was to get an apparatus suited to stand the work, and he wished to ask if such an apparatus could not be found in that employed for the making of water-gas.

MR. FAWSITT, in reply, said that in regard to Mr. Henderson's remarks, he was obliged to him for drawing his attention to the existence of calcium acetylene, of which fact he was ignorant. He was quite aware of the existence of potassium acetylene, as prepared by passing acetylene over melted potassium, and when he spoke in his paper of it not having been produced, he really meant under the conditions occurring in the preparation of cyanides previously described. If it were produced under these conditions, it must be produced in the manufacture of potassium, a fact which had not been established. Again, supposing it were produced, it did not follow that it united with nitrogen to form KCN, at least he had seen no proof of it.

As regarded the non-existence of  $K_2C_2O_2$  at high temperatures, he always understood that it was produced at the highest temperatures in the manufacture of potassium, and the method adopted to prevent its formation was to cool the vapour quickly.

As regards Mr. Stanford's question about the production of ammonium cyanide by passing ammonia gas over heated carbon, he could not speak from experience, but judging from the statements made by several able chemists, he should say that there was strong evidence of its production, but whether with facility or not he could not say. In reference to Mr. Tatlock's question as to whether or not cyanogen could be produced by passing nitrogen over heated carbon, the only affirmative statement he had seen was by Delbriich, and he was inclined to believe it; but after testing it as described in the paper, should say, that under the conditions existing in processes described under classes 1 and 2, it was not so produced.

Lastly, the question asked by Mr. Playfair he could not answer from experience. The regenerative principle was patented and applied to an apparatus made by Mr. Mond, but with what success he did not know. As the temperature favourable to the production of cyanide was very high, he did not think that an apparatus worked on this principle could be kept sufficiently hot for the successful working of the process.

## Journal and Patent\* Literature.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

*The Exhibition of Preventive Appliances in Berlin in its Relation to Chemical Industry.* T. Oppler. Chem. Ind. 12, 501—508, 528—532, and 549—556.

THE exhibition was promoted for the display of methods and appliances having for their object the minimising of risk to life or limb where the circumstances include the element of danger. The author has limited his article to a notice of those means which can be employed for the protection of workers in the chemical industries, but the number of these is too large to admit of more than a general reference here. The notices are arranged under several heads.

(a.) *Signal Thermometers.*—A very delicate means of signalling abnormal changes of temperature has been found in the use of a spiral formed of ribbons of steel and brass soldered together, one end being fixed and the other free to close an electric circuit. The difficulty of soldering these two metals tightly enough to withstand prolonged contraction and expansion, however, prevented any great extension of the use of the apparatus, until a method of coating the steel ribbon with nickel has made it possible to make a permanent joint with solder, and of this improved form of thermometer several examples were exhibited, with the addition also of a method of registering the actual changes of temperature by a diagram.

(b.) *Eye Glasses, Respirators, Clothing.*—Specially mentioned is a so-called normal eye-glass, set in a mask of galvanised iron wire, easily adaptable to irregular features, allowing of free circulation of air and of comfort to the wearer by the use of leather padding. Free circulation of air being indispensable to keep down excessive perspiration under the mask, this is provided for in an invention of Director Stroof by a slit between the glasses and the mask. Respirators to be worn in an atmosphere containing noxious gases consist of wet or dry filters of suitable material, or are fitted to a wash-bottle appliance for cleansing the air before breathing. In some cases a breathing apparatus connected by tubing with the outside air, similar to that used by divers, is the only possible. In a report presented by a German Industrial Union, emphasis is laid on the advisability of wearing close-fitting garments by workers attending on machinery. Complete outfits in leather and asbestos were exhibited for use in gunpowder factories.

(c.) *Lighting and Safety Lamps.*—Petroleum lamps were shown constructed on lines similar in principle and object to the "Shaftesbury" safety-lamp, whilst the illumination of spaces containing inflammable vapours or materials is provided for by gas or electric light transmitted from the outside through glass windows. Of the various forms of safety-lamp, the basis rests essentially on the principle invented by Davy, but by enclosing the flame in a cylinder of glass, greater illumination is obtained, and by allowing for the entrance of air at the bottom of the lamp a steadier and brighter light is maintained, with the further advantage that the lamp gives timely warning of the presence of fire-damp. Various contrivances for locking the lamps and for extinguishing and relighting the flame from outside are referred to, and

some forms of safety-lamp are arranged for use with benzene. A safety-lamp for indicating approximately the proportion of explosive gas present, depends on the employment of a flame fed with absolute alcohol, which is readily susceptible to alterations in height and colour in presence of small quantities of inflammable gas.

(d.) *Transport of Corrosive Liquids.*—For drawing off the contents of carboys, a rubber cap fitting over the neck is provided with bent glass tubes and a force pump, the arrangement working like that of an ordinary wash-bottle. For preventing the spitting of liquid in emptying a carboy, a rubber nose-piece having a vent hole is fitted on the neck. Instead of the usual straw packing it is proposed to surround the carboy with infusorial earth which would absorb the corrosive liquid in case of fracture, the packing being easily regenerated after an accident by washing and drying. An automatic arrangement for controlling the admission of compressed air to a montejus is described.

(e.) *Mineral Water Manufacture.*—All the exhibits in this department involve the use of liquid carbonic acid which avoids many of the dangers incidental to the preparation of the gas itself. The safety arrangements comprise separate expansion vessels, pressure gauges, safety-valves, and automatic pressure-reducing valves. As a provision against possible fracture of the iron cylinder containing liquid carbonic acid, it is enclosed in a strong case of iron trellis work.

(f.) *Varnish and Pitch Manufacture.*—To minimise the chance of firing in case the liquid should boil over the sides of the vessel, the furnace is separated from the boiling house by fire-proof walls. Vessels for boiling lined oil are movable on wheels along a line of rails, so as to afford easy removal when necessary. Foul smelling vapours are drawn by a draught through a coke fire.

(g.) *Soap Manufacture.*—To avoid the dangers incidental to shallow boiling vessels, the rendering copper is made deep and is surmounted by a hood.

(h.) *Lamp-black Manufacture.*—An automatic apparatus for the deposition and collection of lamp-black in a closed chamber provided with windows for observing the progress of the operation. A vertical revolving shaft carries plates cooled with water, on which the lamp-black accumulates, the deposits being removed and delivered into receptacles by scrapers.

(i.) *Match Manufacture.*—Dipping machines for pointing the matches with igniting composition, and a mixing vessel for preparing the composition, are made to work automatically and in a closed chamber, by which all danger to the workmen from phosphorus fumes is avoided.

(k.) *Glue Manufacture and the Grinding of Bones and Slag.*—The bleaching of glue with sulphurous acid and the subsequent drying of it are carried out in a closed chamber through which a current of air is maintained, carrying the sulphurous acid and moisture to a chimney. This method is applied to the grinding and treatment of bones, mineral phosphates and Thomas slag, where injurious dust and acid vapours are given off. Roller mills are closed in by curtains or boxes, and the dust is conveyed by a draught of air to a chamber containing baffling arrangements to cause the deposition of the dust. The ground material is sifted as it comes from the mill, and the coarser particles are returned automatically to the mill, thus confining the grinding practically to one operation. Some of the mills consist of revolving drums of metal containing steel balls. Draughts of air are used to remove foul smells from raw bones and the vapours evolved in the treatment of phosphates in all cases where the workmen would be inconvenienced by them.

(l.) *Disposal of Dust.*—The means noticed under this head are comprehended under two general methods, that of the well-known "Cyclone" dust collector, and of chambers containing flannel or other kind of filtering cloth from which the accumulated dust is periodically removed by shaking or beating.

(m.) *Soda. Caustic Soda.*—The revolver furnace for making soda ash represents the latest successful method

\* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d. ....	½d.
Above 8d., and not exceeding 1s. 6d. ....	1d.
" 1s. 6d.,     "     "     2s. 4d. ....	1½d.
" 2s. 4d.,     "     "     3s. 1d. ....	2d.

of reducing the inconvenience to workmen to a minimum, whilst the use of protective shields and rails of ictal are prescribed to ward off danger in attending to caustic pots. The chemical factory "Rhenania" exhibited a model, including all the protective means applicable to a factory making soda and caustic by the Leblanc process.

(n.) *Manufacture of Explosives*.—Photographs of arrangements in use in various factories were exhibited. Gases given off in the preparation of fulminate of mercury are drawn off into a chimney, whilst danger from accidental explosions is provided for by the use of wire network surrounding the apparatus. Arrangements for submerging in water certain portions of the apparatus of a gunpowder factory are set in motion by the force of an explosion when that should occur from any cause.—G. H. B.

## PATENTS.

*Improvements in Machinery for the Separation of Solid Matters from Liquids, and for Washing Out and Exhausting the Solid Matters so Separated.* W. S. Squire, London. Eng. Pat. 3065, February 21, 1889. 8d.

THE separation of the solid and liquid matters is effected by a machine, which consists of four inclined, revolving cylinders, constructed of perforated metal, wire gauze, or of cloth stretched upon suitable frames, and having troughs underneath them to receive the liquid which passes through, while the solid matter is discharged at the lower end of the cylinder into receivers, each of which is provided with an agitator to mix the solid matter with any liquid that may be added to it, and a pump to remove the mixture so made. The solid and liquid matters are made to travel from cylinder to cylinder in contrary directions; the former thus meets liquid becoming more and more dilute, whilst the latter meets matter more and more charged with soluble material, thus a very concentrated solution of the soluble matter is obtained on the one hand, while on the other the solid matter is obtained thoroughly exhausted of its soluble constituents. When the exhaustion is not completed a larger number of cylinders may be used. There are two claims and two sheets of drawings.—E. S.

*Improvements in Apparatus for Filtering Liquids, or for Preparing Extracts from Substances.* M. J. E. Vassel, Paris, France. Eng. Pat. 3736, March 2, 1889. 11d.

THE invention relates to improvements in "apparatus for rapidly filtering liquids in closed vessels, wherein the air is exhausted from the receiving chamber below the filter, and is forced into the space above the liquid to be filtered." The apparatus can also be transformed into an exhausting apparatus, with intermittent or continuous circulation, and it may be employed in preparing extracts, such as making coffee, and for other purposes. The apparatus consists of a vessel with a tubular lower end, containing the filtering medium and the liquid to be filtered, and which fits into a receiver for the filtered liquid. The inlet valve of a small air-pump, which may be a caoutchouc ball, with valves such as are used for spraying purposes, communicates by a tube with the receiver, and the outlet valve with the top of the filtering vessel. On working the ball, the air is exhausted from the receiver, and passing into the filtering vessel, produces considerable pressure, and thus forces the liquid rapidly through the filtering medium into the receiver. Various modifications of the apparatus are shown on the six sheets of drawings which accompany the specification. There are 11 claims.—E. S.

*An Improved Method or Process of and Apparatus for the Lixivation of Various Materials.* H. H. Lake, London. From "La Société Anonyme des Parfums Naturels de Cannes," Paris, France. Eng. Pat. 10,361, June 25, 1889. 8d.

See under XX., page 325.

*An Improved Method of and Apparatus for the Treatment of Smoke.* S. Elliot, Newbury. Eng. Pat. 12,460, August 7, 1889. 11d.

A stop valve or door is inserted in factory chimneys, and the smoke sucked by means of an exhaust apparatus and driven through a tank in which, by mechanical appliances, water is kept agitated, and the soluble gases and soot are retained. For brick kilns or pottery chimneys a cone or inverted cup requires to be fitted on the top of the chimney and connected with the exhaust apparatus. There are three sheets of drawings giving details.—D. A. S.

*An Improved Machine for the Purpose of Washing and Refining Fuller's Earth, China Clay, and other similar Substances.* W. A. Sheppard, Midford. Eng. Pat. 20,561, December 21, 1889. 6d.

THE machine patented consists of a tank, in which is placed the Fuller's earth or similar material to be treated, and in which it is mixed with water, a second tank provided with an agitator to complete the mixing, and a "refining machine," consisting of two stationary concentric cylinders and an inner vessel like an inverted cone, having slots in, and projecting strips on, its sides, by the rotation of which, at about 100 revolutions per minute, the coarser particles are driven against the walls of the inner cylinder and fall on to the bed-plate at its base, whence they are swept into the annular space between the two cylinders by curved radial arms revolving with the inner vessel, and can be removed from time to time. The finer particles remain in the inner vessel and flow away, suspended in the wash water, through a pipe at its base into settling tanks.—B. B.

## II.—FUEL, GAS, AND LIGHT.

### PATENTS.

*Improvements relating to Artificial Fuel, Refractory Material for Lining Retorts, and Bricks and Tiles.* R. Stone. Eng. Pat. 13,768, September 24, 1888. Amended January 8, 1890. 4d. (Compare this Journal, 1889, 872.)

THE amendment relates to the percentage composition of one of the fuels. Instead of 3 per cent. of oil and 94 per cent. of peat to 3 per cent. of sulphuric acid, 3 per cent. of the acid is mixed with 75 per cent. of oil and 22 per cent. of peat.—D. A. S.

*Improvements in Apparatus for Generating and Burning Gases from Hydrocarbon Oil and Water.* H. Darby, London. Eng. Pat. 2796, February 16, 1889. 8d.

THE improvements consist in a feed-water regulator supplying water by syphon action from a reservoir to the steam generator, and a series of superheating pipes through which the steam passes before mingling with the oil to be burned. For details the specification must be consulted.—O. H.

*Improvements in the Manufacture of Fuel.* A. Besson, Paris, France. Eng. Pat. 4288, March 12, 1889. 4d.

WOOD charcoal in dust or powder is mixed with a silicate, the mixture diluted with water, and powdered anthracite or other mineral coal added till of suitable consistency, when the mass is moulded. 5 per cent. of silicate and 10 per cent. of wood charcoal with 85 per cent. of anthracite, are said to give a good result.—D. A. S.

*Improvements in or relating to Apparatus for the Manufacture of Water-Gas.* F. H. Briggs, Torquay. Eng. Pat. 6090, April 9, 1889. 8d.

A NUMBER of retorts are arranged and worked in series in connexion with a superheater, consisting of a coil covered with a thin protective coating of chalk or fireclay and heated by the products of combustion of the fuel used in heating the retorts or chambers. Arrangements are described for throwing each retort, as the carbonaceous matter contained in it becomes exhausted, out of the series, and connecting again to the end of the series as soon as recharged and reheated.—O. H.

*Improvements in Appliances for Burning Heavy Hydrocarbon Oils, which Improvements are also Applicable to other Purposes wherein it is desirable to Maintain a Fluid at a Constant Level.* M. Blaman, London, and F. M. Sims, Manchester. Eng. Pat. 10,724, July 3, 1889. 8d.

To render it easier to burn heavy hydrocarbon oils, the patentees combine an air-tight pneumatic reservoir with an overflow chamber on a level with the burner so that the level of the oil can be automatically maintained in the burner.—D. A. S.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Fucosol.* K. Bieler and B. Tollens. Ber. 22, 3062—3064.

THE authors claim priority over Maquenne (this Journal 1889, 974) in having established the constitution of fucosol, of Stenhouse. Fucosol obtained from marine algae is not a homogeneous compound, but consists of a mixture of methyl furfuran and furfuran identical with that contained in bran.—J. B. C.

*Fichtelite.* E. Bamberger and L. Strasser. Ber. 22, 3361—3368.

ONE of the authors (this Journal, 1889, 382 and 383) pointed out some time ago that all endeavours, his own included, to get at the constitution of fichtelite by chemical means had failed. At the end of the communication a reaction was described, which has since, in conjunction with the researches of Liebermann and Spiegel, thrown a great deal of light on the subject. In order to definitely fix the empirical formula and molecular weight of fichtelite, a number of carbon and hydrogen determinations made by different observers were collected, and the boiling point and vapour density were also carefully determined. The boiling point (corrected) of fichtelite was found to be  $355.2^{\circ}\text{C}$ . at 719 mm. pressure,  $235.6^{\circ}\text{C}$ . at 43 mm., and  $233.6^{\circ}\text{C}$ . at 42 mm. These numbers exclude the possibility of fichtelite being a di- or tetrahydrosesquiterpene, since the sesquiterpenes boil at about  $250^{\circ}\text{C}$ ., and the hydrides would boil at a still lower temperature. The vapour density, determined in an atmosphere of nitrogen, was found as the mean of two experiments to be 8.69. This vapour density, in conjunction with the elementary composition of fichtelite, points to the formula  $\text{C}_{18}\text{H}_{32}$  for that body. This formula differs from that of retene by a plus of 14 atoms of hydrogen; and as retene and fichtelite both occur in peat, and probably both are fossil products of vegetable resin, it was considered not improbable that a connexion might exist between the two.

Now Liebermann and Spiegel obtained by the exhaustive reduction of retene, not perhydroretene, but dodecahydroretene, which contains two atoms of hydrogen less than fichtelite. After vainly employing various reagents the authors succeeded in abstracting two atoms of hydrogen from fichtelite by means of iodine.

*Dehydrofichtelite* forms a clear, colourless, viscid liquid, possessing a splendid blue fluorescence. It boils at  $344^{\circ}$ — $348^{\circ}\text{C}$ . under a pressure of 714 mm. It is with difficulty soluble in cold glacial acetic acid and in alcohol, but readily soluble in ether, benzene, chloroform, and carbon disulphide. Dehydrofichtelite,  $\text{C}_{18}\text{H}_{30}$ , possesses all the properties ascribed by Liebermann and Spiegel to retene dodecahydride. The boiling point of the latter is given by Liebermann and Spiegel as  $10^{\circ}$  lower than that of dehydrofichtelite; but this seeming discrepancy disappears when it is considered that their boiling point is uncorrected. A point deserving more consideration is, that although the authors obtained from dehydrofichtelite a hydrocarbon which yielded on oxidation an orthoquinone, they were yet unable to positively identify either retene or retenequinone. Still, as Liebermann and Spiegel state that retene-dodecahydride yields on distillation with zinc-dust but a small quantity of retene, it is quite possible that owing to the small amount of substance worked with, these bodies escaped detection. On these grounds the authors are of opinion that the identification of fichtelite as perhydroretene is almost a certainty. By the further action of iodine on dehydrofichtelite, tetrahydrofichtelite is obtained, which is very similar in all respects to dehydrofichtelite. All attempts to carry the dehydrogenation still further have failed. By the treatment of dehydrofichtelite in the cold with bromine, beautiful glassy prisms were obtained, apparently containing bromine in an additive form. The authors hope to continue their investigations on this substance.—H. T. P.

*The Constitution of Fichtelite.* L. Spiegel. Ber. 22, 3369—3371.

It has been shown by various observers that fichtelite is exceedingly stable towards most reagents. The author and Liebermann had noticed this same property in the perhydrides of aromatic hydrocarbons. This fact led the author to suspect the existence of a connexion between retene and fichtelite, which both occur in peat. The perhydride of retene would be  $\text{C}_{18}\text{H}_{32}$ , which is also the formula of fichtelite. The author and Liebermann (Ber. 22, 779; this Journal, 1889, 451) were unable to obtain perhydroretene, but they succeeded in preparing retene dodecahydride,  $\text{C}_{18}\text{H}_{30}$ , which possesses all the properties ascribed by Bamberger (see preceding abstract) to dehydrofichtelite,  $\text{C}_{18}\text{H}_{30}$ , and which is prepared by the action of iodine on fichtelite. To prove the correctness of the assumption—based on the above facts—that fichtelite is perhydroretene and possesses the constitutional formula—

the author is endeavouring to prepare fichtelite from retene. Already some time ago the author obtained by freezing and pressing a large quantity of crude retene dodecahydride a small proportion of a crystalline body, melting at  $48^{\circ}\text{C}$ . The substance also seems to be formed by the treatment of retene dodecahydride with phosphorus and hydriodic acid. The author is continuing his researches on this compound and hopes to prove its identity with fichtelite.—H. T. P.

*The Sulphur Compounds in Crude Petroleum and in Petroleum Residues.* C. F. Mabery and N. W. Smith. Ber. 22, 3303—3305.

This is a research on the form in which sulphur exists in petroleum from the Ohio oil-fields.

The sulphur compounds occur chiefly in the higher boiling-point fractions 200°—300°. From this they were readily obtained by treatment with strong sulphuric acid. The diluted acid solution was neutralised with lead carbonate or calcium hydrate. The salts so formed were very unstable and easily decomposed in aqueous solution by distillation with steam, giving as distillate a clear yellow oil.

The authors worked on a measured quantity of this oil of sp. gr. 0.9245 at 16.5°, and containing 14.97 per cent. of sulphur. When distilled without steam at ordinary pressure it decomposed, giving off sulphuretted hydrogen. It was therefore distilled under a reduced pressure of 100 mm. and collected in fractions.

Fractions containing sulphur:—

	Per Cent.
80°—90°.....	None.
100°—105°.....	18.23
135°—140°.....	15.52
150°—155°.....	16.44
185°—190°.....	14.21

The absence of mercaptans and the presence of sulphides in all was found.

Bromine vapour caused a thick white cloudiness with all fractions; liquid bromine combined with explosive violence. Bromine water formed readily a heavy oil.

80°—90° fraction. Bromine compound gave by analysis  $C_{17}H_{14}Br_2$ . The hydrocarbon may thus be identical with that of Pelletier and Walther (Berzelius, Jahresb. 21, 470).

HBr formed an oily product heavier than water with fractions below 135°, the 80°—90° fraction being wholly converted. This heavy oil had the characteristic odour of substituted ethanes.

100°—150°. An alcoholic solution of mercuric chloride formed hard crystals either on standing or by crystallisation from benzene.

100°—120°. The mercuric chloride addition compound crystallised from benzene answered to the composition  $(C_{17}H_{14})_2SHgCl_2$ .

135°—140°. The addition compound showed  $(C_{17}H_{14})_2SHgCl_2$ . It decomposed on melting at 140°.

150°—160°. The addition compound, as in case of the higher boiling point fractions, was a thick viscid oil. Instead of corresponding to  $(C_{17}H_{14})_2SHgCl_2$ , it consists probably of a mixture of ethyl and propyl sulphides.

98°—101°. The addition product, as in case of lower boiling point fractions, formed hard crystals, and was probably a mixture of propyl and butyl sulphides.

The bromine compounds were not further examined on account of the difficulty of purifying them.

The authors are further investigating the nature of these compounds.—D. A. S.

*On Cumaron in Coal Tar.* G. Kraemer and A. Spilker. Ber. 23, 78—83.

CUMARONE may be obtained from the portion of the light tar oils boiling at 168°—175°, after phenols and pyridine bases have been removed by extraction with alkali and acid. One kilo. of this purified tar oil is slowly mixed with 450 grms. bromine, the temperature not being allowed to rise over 0°. The oil is first coloured intensely red, then reddish-brown, and a yellowish-white crystalline mass separates out, which is at once filtered off through glass wool. The filtrate is left for 24 hours at 5° to 10°, when a further 80 grms. of large prismatic crystals are deposited, which are purified by recrystallisation from chloroform. The formula of the substance is  $C_8H_6Br_2O$ , and it must be regarded as the dibromide of cumaron. By heating with alcoholic potash, the monobromide is formed, crystallising from dilute alcohol in prismatic crystals, melting at 39° and boiling at 219°—220°. By acting on a dilute alcoholic solution of the bromide with sodium amalgam the bromine

is slowly replaced by hydrogen. The oil obtained is almost pure cumaron, boiling at 170°—171°. The dichloride is readily prepared by passing chlorine into a dry ethereal solution of cumaron. It is a yellowish oil, boiling at 245°—248°. The monochloride is obtained from it by the action of alcoholic potash. It melts at 74°—75°, and boils at 215°—217°.

Cumaron is not acted on by aqueous or alcoholic or even melted potash. It is likewise indifferent to the action of hydrochloric acid and potassium cyanide, ammonia or zinc-ammonium-chloride at 300°. Oxidising agents, such as permanganate and chloride of lime, act on it vigorously.

Cumaron is so stable a body that if 100 grms. be passed through a red-hot tube 94 grms. are recovered unchanged. Sulphuric acid, however, readily acts on it with formation of a polymer, which is called paracumaron. The latter is resinous, and its alcoholic solutions are said to be of use for covering wood and metal, as the layer is perfectly unaffected by acids or alkalis.

By using an excess of sulphuric acid another polymer of cumaron is produced. It is at first soft and finally turns into a brittle infusible mass insoluble in all solvents. On heating cumaron with sulphuric acid, sulphonic acids probably result.

Cumaron stands midway between two other well-known products of dry distillation, thus—

This series is typical of a large number of similarly constituted bodies found in coal tar, a systematic table of which is appended (see top of next page):—

Besides cumaron there are similarly constituted bodies in various fractions of coal-tar oils. In fact it is the presence of these substances which cause the characteristic colourations when solvent naphtha is treated with sulphuric acid. The authors have also discovered benzonitrile in the tar oils which they used for obtaining cumaron. This is no doubt the source of the benzoic acid found by K. E. Schultze in phenolic residues, for it is not probable that benzoic acid is present in the distillation products of coal tar, seeing that at the high temperature it would be sure to unite with ammonia with ultimate formation of benzonitrile.—A. R.

*Synthesis of Chrysene and Similar Hydrocarbons.* G. Kraemer and A. Spilker. Ber. 23, 84—87.

KLOTZ discovered some years ago that the best method of preparing chrysene from certain fractions of solvent naphtha was to pass the latter through heated tubes, and he was able to obtain about two per cent. of chrysene from the original oil by this process. The authors having placed beyond doubt the presence of cumaron in heavy tar oils (see previous abstract), were led to believe that that substance had a good deal to do with the production of chrysene. When passed through red-hot tubes cumaron remains unchanged. But if mixed with naphthalene considerable quantities of chrysene are formed. This was to be expected, seeing that 1 mol. of cumaron and 1 mol. of naphthalene need only lose 1 mol. of water to give 1 mol. of chrysene. The quantities of the latter which were obtained in this manner only amounted to about  $\frac{1}{3}$  per cent. of the mixture, but no doubt more will be formed when the tube through which the mixture is passed can be heated more effectually or is filled with dehydrating agents. It may be added that naphthalene vapour alone gives under the above conditions no trace of chrysene. The reaction which takes place is plainly visible from the equation—

The ready manner in which this process could be carried out led to a consideration as to whether it were not possible to explain the production of a variety of other bodies in coal tar by equally simple reactions. It was but natural to

					Fluorene.

try the synthesis of phenanthrene from eumarone, and here also the authors were successful. On passing the vapour of eumarone and benzene through red-hot tubes, these substances reacted on each other with formation of phenanthrene according to the equation—

Now most of the phenanthrene in coal tar cannot be derived from the eumarone. Gräbe has in fact shown that the former is always produced when the vapours of toluene, stilbene, or dibenzyl are passed through hot tubes. Of these, however, it is only the first that we can regard as a great source of phenanthrene; eumarone no doubt comes next. Whether on passing the vapour of toluene and eumarone through red-hot tubes, the latter remains unchanged and the former alone takes part in the production of phenanthrene, or whether both substances react on each other with formation of methylphenanthrene, has not yet been ascertained. The authors in fact believe it will be possible to build up a variety of hydrocarbons starting with eumarone. Thus they expect that an isomer of naphthalene, if not naphthalene itself, can be prepared from ethylene and eumarone. Moreover there is large scope for interesting work in trying to bring about condensations between eumarone and phenols or indoles (carbazol) as well as with furfuran. The authors are however unable to pursue the subject further, and invite others to devote themselves to this promising field of research.—A. R.

*Phenyl-thiophen.* A. Renard. *Compt. Rend.* **109**, 699—700.

This body is prepared by passing a mixture of toluene and sulphur vapour through an iron tube heated to redness. The toluene is introduced into the tube drop by drop at the same time that small fragments of sulphur are introduced through a lateral tube, the proportions of the two substances being equal. A black product is obtained, which solidifies

on cooling, and gases consisting of sulphuretted hydrogen and carbon bisulphide are evolved. On distilling the black product some  $\text{CS}_2$  and toluene pass over; the temperature then rises and a liquid distils which solidifies in the receiver to a yellow mass. This product may be purified by recrystallisation from alcohol, in which another thiophen derivative dissolves which has not been fully investigated. Phenyl-thiophen crystallises in colourless crystals melting at  $170^\circ$ . It gives with isatin and concentrated sulphuric acid a blue colouration. The author has prepared from this compound dibromo-di- and di- and tetra-sulphonic acid derivatives.—J. B. C.

*On Homologues of Anthracene and Anthraquinone.* K. Elbs. *J. prakt. Chem.* **41**, 1—32. (See this Journal, 1886, 321; and *J. prakt. Chem.* **35**, 466.)

THE following method for the production of homologous *o*-benzoyl-benzoic acids is described. One part of aluminium chloride and two parts of carbon disulphide or petroleum ether are introduced into a large flask with a reflux condenser, a mixture of one part phthalic anhydride and the respective hydrocarbon (one mol. to one mol. phthalic anhydride) is then added. The reaction usually commences directly with a strong evolution of hydrochloric acid, if not, the flask may be warmed. The mixture is left on the water-bath till the evolution has almost ceased; 6—12 hours usually suffices. The cooled residue is agitated with a little water, some crude hydrochloric acid is poured in through the condenser, and the mixture heated to boiling. The contents are then transferred to a tubulated retort, and steam introduced. Carbon disulphide or petroleum ether, or any unchanged hydrocarbon distil over, leaving unchanged phthalic anhydride as phthalic acid and aluminium in solution. The benzoyl-benzoic acid collects as a thick heavy oil at the bottom, and after pouring off the superabundant liquid, it can be washed and purified, either by Meyer's method (*Ber.* **15**, 636) from the highly-crystalline ammonium salt, or by crystallisation from benzene, acetic acid, or alcohol. The yield is increased by use of excess of the hydrocarbon.

*β-methylanthracene*,  $C_6H_4 : (C_2H_5) : C_6H_3 \cdot CH_3$ , melting point  $199^\circ-200^\circ$ . Prepared by boiling *p*-xylylphenylketone for 12 hours, and then distilling. The distillate is stirred to thin consistency with alcohol, the alcohol drawn off, and the precipitate recrystallised from a mixture of benzene and alcohol or acetone and alcohol; also from *m*-xylylphenylketone or from *m*-xylylphenylcarbinol—from the latter easily, as shown:—

Or by reduction of the following compound—

*β-methylanthraquinone*,  $C_6H_4 : C_2O_2 : C_6H_3 \cdot CH_3$ , melting at  $176^\circ-177^\circ$ , by treating *p*-tolyl-*o*-benzoic acid with strong sulphuric acid, diluting with water, filtering, and drying the precipitate, and purifying it by sublimation.

*o*-dimethylanthracene,  $C_6H_4 : (C_2H_5) : C_6H_2 \cdot (CH_3)_2$  [ $CH_3 : CH_3 = 2 : 3$ ]. In yellow plates melting at  $246^\circ$ . Sublimes in bluish-green fluorescent plates. Made by reduction of (2:3) dimethylanthraquinone with zinc dust and ammonia. A picric acid derivative was formed in garnet red needles, which decomposed from  $108^\circ-125^\circ$ , but could not be prepared pure for analysis.

*o*-dimethylanthraquinone,  $C_6H_4 : C_2O_2 : C_6H_2 \cdot (CH_3)_2$  [ $CH_3 : CH_3 = 2 : 3$ ]. In long yellow needles melting at  $183^\circ$ . By treating *o*-xylyl-*o*-benzoic acid with strong sulphuric acid, diluting, allowing to stand 2—3 days to crystallise, and filtering through glass-wool. Purified by sublimation or by crystallising from boiling xylene.

A (3:4) *o*-dimethylanthraquinone could also be obtained from *o*-xylyl-*o*-benzoic acid. But the preparation of *o*-dimethylanthracene by reduction with zinc dust and ammonia shows the above-described to be the (2:3) compound.—*Anthraquinone-o*-dicarboxylic acid—

In yellow needles melting at  $340^\circ$ , insoluble in water, but soluble in cold alcohol. By oxidation of foregoing compound with dilute nitric acid by heating at  $220^\circ$ . On heating it sublimes, giving—

*Anthraquinone-o*-dicarboxylic Anhydride—

In yellow lustrous plates melting at  $280^\circ$ , insoluble in water, but soluble in alcohol and ammonia. The ammonium, calcium, lead, and silver salts, all red in colour, of the above acid are described.

*Anthracene-o*-dicarboxylic Acid—

In greenish-yellow crystals, melting at  $345^\circ$ , insoluble in water, but soluble in alcohol and ammonia. It gives, on subliming—

*Anthracene-o*-dicarboxylic Anhydride—

The calcium (brownish-green), lead (yellow), and silver (brownish-yellow) salts are described.

*m*-Dimethylanthracene—

By condensation of methylphenylketone (J. prakt. Chem. 35, 480) or by reduction of *m*-dimethylanthraquinone with zinc dust and ammonia (Ber. 20, 1365; see also Bull. 44, 167, and Ann. Chem. 234, 240), the picric acid derivative was similar to the *o*-derivative. A bromine derivative is also described.

*m*-Dimethylanthraquinone—

melting at  $162^\circ$ , by treating recrystallised *m*-xylene-*o*-benzoic acid with strong sulphuric acid.

By reduction of *m*-dimethylanthraquinone with zinc dust and ammonia, a hydrocarbon was obtained in small colourless plates, melting at  $85^\circ$ , soluble in hot alcohol, darkening in presence of air and light. By treatment with a saturated alcoholic solution of picric acid a derivative was formed, melting at  $135^\circ$ , and soluble with difficulty in alcohol.

From the analysis of the hydrocarbon and the above derivative, the author concludes that it is *m*-dimethylanthracene,  $C_{16}H_{12}$ .

Generated from a pre-existing *m*-dimethylanthranol by abstraction of its hydroxyl and an atom of hydrogen (from its ortho-methyl group) as water.

*m*-dimethylanthranol,  $C_{16}H_{14}O$

was obtained in varying quantities by the same reduction in small colourless needles, melting at  $155^\circ$ , darkening in air, insoluble in water, but soluble in alcohol, carbon disulphide or warm alkalis.

The bromination of *m*-dimethylanthracene gave no addition product, but a substitution one was formed, namely:—

*m*-Dimethylanthracene dibromide,  $C_{16}H_{10}Br_2$ —

In sulphur yellow prisms, melting at  $175^\circ$  and decomposing, giving off hydrobromic acid, soluble in carbon disulphide and acetone, and only with difficulty in ether and alcohol. The author confirms the above formula by an experiment to show the absence of a bromine atom in the benzene ring.

*Anthraquinone-m*-dicarboxylic Acid—

In yellow needles, melting at  $330^\circ$ , insoluble in water, and soluble only with difficulty in any of the usual solvents.

By oxidation of *m*-dimethylanthraquinone with dilute nitric acid.

Its neutral salts of ammonium, potassium, sodium, calcium, barium, lead (all reddish coloured), copper (deep green), and silver (rose coloured) are described. The chloride is also described. The amide crystallised badly, and showed no characteristics.

*Anthracene-m*-dicarboxylic Acid—

A brownish yellow crystalline powder, melting at  $330^\circ$ , and easily soluble in all solvents. By reduction of the foregoing acid with zinc dust and ammonia. The ammonium and copper (both green) and the silver (brownish yellow) salts are described, as is also the chloride.

*p*-dimethylanthraquinone—

In yellow needles melting at  $118^\circ-119^\circ$ , soluble with difficulty in alcohol, but easily in benzene and xylene. From *p*-xylyl-*o*-benzoic acid by abstraction of water with strong sulphuric acid.

By reduction of the foregoing with zinc dust and ammonia a product crystallising badly was obtained. This yielded a *picric acid derivative* in deep red needles, melting at 129°. By decomposition of this by sodium hydrate a yellow powder was obtained, soluble in alcohol and crystallising in very small yellow plates, melting at 63°. This proved not to be *p*-dimethylantracene, but a hydrocarbon poorer in hydrogen, viz.,  $C_{16}H_{12}$ , and probably of the formula—

#### Anthraquinone-*p*-dicarboxylic Acid—

In yellow crystals, melting at 300°, soluble with difficulty in water, but easily in alcohol. By oxidation of *p*-dimethyl-anthraquinone with dilute nitric acid. The *alkaline salts* are reddish. The *calcium, lead and silver salts* are also all reddish coloured.

#### Anthracene-*p*-dicarboxylic Acid—

A clear brown crystalline powder, melting about 320°. The following neutral salts are described: The *alkaline salts*, blue or bluish green; the *calcium salt* (brown); the *lead salt* (yellowish green); and the *silver salt* (brownish yellow).—D. A. S.

### PATENT.

*Improvements in the Distillation of Mineral Oils, and in the Apparatus employed therefor.* W. Young, Peebles, and G. T. Beilby, Slateford. Eng. Pat. 4597, March 16, 1889. 8d.

This is a process for continuous distillation, wherein it is claimed the more volatile oils assist in the distillation of the less volatile oils, and that by the construction of the still, increased rapidity of distillation is secured.

Fig. 1 shows an elevation of the still in section. Fig. 2 shows a horizontal section on the line A, B.

Fig. 1.

$s$  and  $s^2$  are the outer and inner shells of the still, of malleable iron.  $s^3$  is the crown of inner shell, of cast iron,

$s^4$  partitions dividing the still horizontally into three compartments,  $s^5$  tubular openings covered with loose caps,  $s^6$  vertical partitions to cause circulation of oil,  $s^7$  perforated hinged doors in the partitions,  $p$  oil feed pipe,  $p^2$  oil vapour

Fig. 2.

pipe leading to the regenerative condensers,  $p^3$  perforated steam pipes round each of three compartments,  $p^4$  residue or overflow pipes leading to the coking stills.

In working, oil is fed continuously in at the bottom, and in its progress upwards is subjected to an increasing temperature. The more volatile parts are at once converted into vapour, and in their passage through the still caused to bubble through or come intimately in contact with the less volatile oils, and so take up and carry over the less volatile vapours. Less steam is thus required than in the ordinary system.—D. A. S.

## IV.—COLOURING MATTERS AND DYES.

*The Action of Light in Colouring pure Aniline.* P. Werner. Bull. Soc. Ind. de Mulhouse, June—July 1889, 331—332.

It is well known that when aniline is exposed to air and light it becomes coloured after some time, first yellow, then red, and finally brown. It was deemed of interest to try to discover if this colouration was due to partial oxidation of the aniline, and to study the influence of light upon this colouration. To clear up the question the following trials were made. Pure colourless aniline had been preserved in vacuo, and in an atmosphere of air and of oxygen, one portion in the dark and the other exposed to diffused daylight for three months and a half.

### 1.

#### In Diffused Daylight.

1. *In vacuo.*—The aniline remains absolutely colourless.
2. *Air.*—Yellowish brown colouration. Absorption for 1 gm. of aniline 0.4 cc. on 9 cc. of air.
3. *Oxygen.*—Intense colouration, brownish red. Absorption for 1 gm. of aniline 1.1 cc. on 8 cc. of oxygen.

### II.

#### In the Dark.

1. *In vacuo.*—Aniline remains absolutely clear.
2. *Air.*—Very slight colouration. Absorption inappreciable.
3. *Oxygen.*—Colouration feeble, yellowish. Absorption very slight.

The colouration is thus proved to be due to the action of light. In the light it is also shown that an absorption of oxygen takes place, i.e., oxidation, and so the effect is produced by the combined action of oxygen (air) and light.

*On some Colouring Derivatives of Triphenylmethane.*  
E. Noelting. Bull. Soc. Ind. de Mulhouse, 1889, Aug.—Sept. 436—443.

The conditions under which magenta is formed have been particularly studied by Hoffmann, Rosenstiel, Emil, and Otto Fischer and Rosenstiel and Gerber. Rosenstiel and Gerber distinguish three classes, according to the manner in which the homologues of aniline behave towards oxidising agents.

**First Class.**—Bases which when oxidised with arsenic acid by themselves do not yield colouring matters, but do so in presence of aniline—

**Second Class.**—Bases which on treatment with arsenic acid yield no colouring matters, but which do when oxidised in presence of a base of the first class—

**Third Class.**—Bases which on oxidation with arsenic acid yield no colouring matters like magenta, neither by themselves nor in presence of any of the two previous classes—

In the first class one methyl group is in the para-position to the amido group, whilst in the bases of the second and third class the para-position is free. In the second class the methyl groups are in the ortho-position, and in the third class in the meta-position to the amido group. E. and O. Fischer's experiments have proved that in the simplest rosaniline the three amido groups are in the para-position to the fundamental carbon atom. The complete analogy of the homologous rosanilines with the first having been proved, it can be readily understood why the members of the first group when oxidised by themselves or with each other do not yield rosaniline, but do so when oxidised in presence of aniline.

In the bases of the second class the para-position is free, and one or two ortho-positions are occupied. It is clear that these bases cannot yield rosanilines, unless they are oxidised with a base of the first group. Neither can the bases of the first class produce magentas, but no reasons yet given can explain why they should not be able to produce rosanilines, when oxidised with the members of the first class. The experiments of Monnet, Reverdin, and

Noelting and of O. Fischer and Koek, have, however, confirmed this experience. Now the question arises whether amido compounds, in which the ortho- and meta-position is occupied, belong to the second or third class. Such amines are—

Experiments made with all these bases in their absolutely pure state prove that they belong to the third class. Not a trace of colouring matter was obtained when oxidised by themselves or in presence of para-toluidine,  $\alpha$ -metaxylydine, or mesidines. The presence of a methyl group in the meta-position to the amido group renders these bases incapable of forming rosanilines.

Another question arose, whether the presence of a methyl group in the meta-position in the bases of the first class would influence their capacity for forming rosanilines. In the first three bases of this class the meta-positions are free, in the last two the ortho- and one or two meta-positions are occupied. But how meta-methylated paratoluidines would act remained to be seen.

The following are ortho- and meta-methylated paratoluidines—

whilst—

are only meta-methylated.

All these bases yield rosanilines in abundance, when oxidised with aniline, orthotoluidine, and  $\gamma$ -metaxylydine.

The author further shows that there are 30 isomeric rosanilines possible, if 1 mol. of a para base be oxidised with 2 mols. of either aniline, orthotoluidine or  $\gamma$ -metaxylydine, but that this number may be increased to 60, if instead of taking 2 mols. of the same base of the second class, 1 mol. of aniline and 1 mol. of orthotoluidine, &c. be used. However, some of the latter 30 compounds are identical either among themselves or with bodies of the first 30; there exist in reality only 52 isomeric and homologous rosanilines.

It remains to be decided whether a rosaniline can be obtained by oxidising 1 mol. of a base of the first class with 1 mol. of a base of the second class, and 1 mol. of a base of the third class.—A. L.

*Researches on Colouring Matters of the Triphenylmethane Group.* E. Noelting. Bull. Soc. Ind. de Mulhouse, 1889, Aug.—Sept. 444—446.

*Condensation of Tetramethyldiamidodiphenylcarbinol with Meta-substituted Amines.*—Kern has discovered that tetramethyldiamidodiphenylcarbinol can be condensed with amines, and that the compound yields on oxidation derivatives of rosaniline. He used as amines the primary, secondary, and tertiary derivatives of aniline, orthotoluidine, and  $\alpha$ -naphthylamine, but no meta-substituted compounds. The author prepared the condensation products from meta-toluidine, paraxylydine,  $\beta$ -orthoxylydine,  $\beta$ -metaxylydine

amidines of Edler and Mayer, and the crystallised duridine with tetramethylamidodiphenylcarbinol, all of which form on oxidation with chloranil blue-violet colouring matters. The secondary and tertiary compounds of these meta-substituted bases yield also colouring matters similar to those obtained from the primary amines.—A. L.

*Note on the Ethylenic Ethers of the three Amido-phenols and some Colouring Matters from them.* C. Krohn. Bull. Soc. Ind. de Mulhouse, 1889, Aug.—Sept. 16—17.

THE three amines—

are distinguished from each other by the colour with which they dye woody fibre (lignin). The para-compound dyes woody fibre orange, the meta- and ortho-compound dye it yellow. The azo-colouring matters prepared from these bases differ in their affinity for vegetable fibre. The para-compounds dye cotton directly very well, the meta derivatives badly, and the ortho-compounds not at all. By combining ethylene-para-amidophenol with  $\alpha$ -naphthol- $\alpha$ -sulphonic acid, a beautiful red, fast to acids, is obtained; with resorcinol, an orange; with salicylic acid, a fine yellow. With naphthionic acid it forms an orange, with  $\beta$ -naphthylamine- $\delta$ -sulphonic acid, a reddish orange, and with Brömer's  $\beta$ -naphthylamine sulphonic acid a still redder orange. These three colours are altered by acids.—A. L.

*The Synthesis of Metaphenylene-diamine from Resorcinol and Ammonia.* A. Seyewitz. Compt. Rend. 109, 814—817.

A MIXTURE of resorcinol and ammoniacal calcium chloride, obtained by saturating calcium chloride with dry ammonia, is heated in a sealed tube for three hours between 280° and 300° C. The mass is treated with cold water, and the aqueous solution repeatedly extracted with half its volume of ether. The ethereal solutions are saturated with hydrochloric acid gas, when the base crystallises out as the hydrochloride. The yield is 60 grms. per 100 grms. of resorcinol taken. The author gives details of variations in time and temperature of the reaction, but prefers the figures as given above.—S. G. R.

*Synthesis of Dihydroxydiphenylamine and of a Reddish-Brown Colouring Matter.* M. Seyewitz. Compt. Rend. 109, 946—949.

A MIXTURE of resorcinol with four times its weight of ammoniacal calcium chloride were heated for about 10 hours in sealed tubes from 190° to 260°. The tubes were found to contain a deep yellow colouring matter, which was powdered, digested with water, and filtered. The filtrate was neutralised with hydrochloric acid; this precipitated a further quantity of the same substance, which had remained on the filter. After drying in vacuo over sulphuric acid, the residue was dissolved in a little alcohol and filtered. On now adding water to the red solution, which also shows a fine green fluorescence, brown flakes separate out. They are purified by repeated crystallisations. An analysis led to results justifying the formula  $\text{HO}\cdot\text{C}_6\text{H}_3\cdot\text{NH}=\text{C}_6\text{H}_4\cdot\text{OH}$ , and this was corroborated by the behaviour of the body towards acids, alkalis, nitrite of soda, and diazo-bodies. Also, on heating with zinc powder, diphenylamine was obtained.

By heating the above-mentioned mixture of resorcinol and ammoniacal calcium chloride for eight hours at 300°, a reddish-brown dye is obtained. This is readily diazotised, and then reacts on phenols with formation of other dyes. On cotton mordanted with tannin and tartar emetic a fast brown is produced. Wool which has been treated with bichromate is coloured in good shades, which are fast to milling.—A. R.

*On a New Class of Diacetones.* A. Béhal and V. Auger. Compt. Rend. 109, 970—973.

MALONYL chloride, as well as ethyl- and methyl-malonyl chloride, react with aromatic hydrocarbons with formation of  $\beta$ -diacetones  $\text{R}\cdot\text{CO}\cdot\text{CHX}\cdot\text{CO}\cdot\text{R}$ . By using ethyl-malonic acid, substances are obtained giving characteristic blood-red solutions on adding an alkali or an alkaline carbonate. The best results have been obtained with *m*-xylene and the chloride of ethylmalonic acid. The diacetone obtained by the aid of aluminium chloride melts at 63°. Its formula is  $\text{C}_{13}\text{H}_{14}\text{O}_5$ . The red colouration produced by alkalis is due to the H-atom which is attached to the carbon atom situated between the two carbonyl groups. If the H-atom be replaced by ethyl, the diketone is no longer coloured red by alkalis. We may therefore regard these diketones as containing a new chromogen group. The tinctorial properties of these bodies are lost by oxidation with ferrocyanide, when tetraketones are produced.

The diketone from ethylmalonic acid yields a dioxime melting at 235° with hydroxylamine, which confirms the presence of the two carbonyl groups. Heated with baryta water to 200°, methylbutyrylphenylacetic acid is produced, of the formula

On oxidising this acid, propionic acid and a dibasic acid  $\text{C}_6\text{H}_3(\text{COOH})(\text{CH}_2\text{COOH})$  result; the latter melts at 178° with loss of  $\text{CO}_2$ . These new diketones therefore possess the remarkable property that one of their carbonyl groups unites with water to form an acid of the same number of carbon atoms as the diketone itself.—A. R.

*Phenanthridine.* A. Pietet and H. I. Ankersmit. Ber. 22, 3339—3344.

HERETO only two of the five isomeric compounds, formed theoretically by the substitution of a nitrogen atom for a CH-group in phenanthrene, have been known. The authors have prepared a third of these, differing from the other two previously known in containing its nitrogen atom in the central ring, and give it the name, already suggested by Etard and Bernthsen, of phenanthridine. The new compound was obtained by passing the vapours of benzylidene-aniline through a tube heated to bright redness, the chemical change being represented by the following equation:—

A brown oil formed the chief product of the reaction. This was examined for the presence of phenanthridine by first submitting it to distillation, and testing the portion boiling above 250°. On treating it with warm dilute hydrochloric acid, and adding mercuric chloride to the solution so obtained, a voluminous precipitate was formed, which was recrystallised from hot water, and washed with boiling alcohol. The base was then liberated from the washed salt, and, after further purification by distillation with superheated steam and crystallisation from dilute alcohol, was analysed, and its chief properties examined, with the results shown in the following table:—

	Acridine.	Phenanthridine.
Melting point, .....	107°	104°
Platinum double salt	Small, stellate needles. Melting point, above 225°.	Small, aggregate needles. Melting point, above 225°.
Gold double salt ....	Long needles, sparingly soluble in hot water.	Long needles, insoluble in hot water.
Mercury double salt	Long stellate needles. Melting point, 225°.	Long stellate needles. Melting point, 130°.

	Acridine.	Phenanthridine.
Bichromate.....	Short needles, almost insoluble in hot water.	Long, fine needles, fairly-easily soluble in hot water.
Picrate.....	Prismatic needles. Decompose towards 200°.	Fine, thin needles. Undecomposed at 220°.
Nitrite.....	Small needles.	Floccy amorphous precipitate.
Sodium sulphite added to solution of the hydrochloride.	Precipitate consisting of small, brown-red needles.	No precipitate.
Potassium iodide added as the last.	Precipitate consisting of long yellow needles.	Yellow, granular precipitate.
Reduction with tin and hydrochloric acid.	Compound without basic properties.	Basic hydro-derivative, crystallising from alcohol in small white needles of melting point near 100°, converted by action of nitrous acid into a nitrosamine.

—E. B.

*The Combination of  $\alpha$ - $\beta$ -Dinaphthylamine with Diazo-benzene.* P. Matthes. Ber. 22, 3341—3348.

On adding a solution of diazobenzene to one of  $\alpha$ - $\beta$ -dinaphthylamine in acetone in the cold and in presence of sodium acetate, there is formed the azo-compound of the following constitution:—

The diazo-nucleus enters the  $\alpha$ -position next to the substituted  $\beta$ -position.

But when the combination of the above compounds is effected in the presence of hydrochloric acid and at a temperature of 40°—50° three azo-compounds are produced. Not only does the diazo-rest enter the substituted  $\beta$ -naphthylamine molecule in the  $\alpha$ -position as above, but it enters the substituted  $\alpha$ -naphthylamine in the para-position, forming the compound represented below:—

In addition a small quantity of a disazo-compound is formed:—

The disazo-compound being much less soluble in alcohol than the two azo-compounds, can be easily separated from the mixture. As the solubilities in most solvents of the two mono-azo-compounds are almost the same, the separation of these is more difficult. Benzene alone dissolves

more of the  $\alpha$ -compound than the  $\beta$ -compound and by repeatedly crystallising from this solvent the latter compound is obtained pure. It crystallises in long, floccy, deep-red needles, melting at 167°. On treatment with mineral acids it is changed into an azine. Advantage is taken of this in the preparation of the pure  $\alpha$ -compound. The acetic acid solution of the two mono-azo-compounds is treated with mineral acid, whereby the  $\beta$ -compound is converted into an azine, the  $\alpha$ -compound being merely converted into the corresponding salt. Both compounds are precipitated by water, then the  $\alpha$ -salt is separated by solution in alcohol in which the azine is practically insoluble. By addition of ammonia to the alcoholic solution the free  $\alpha$ -azo-compound is separated. After recrystallisation from hot alcohol it is obtained in the form of short, thick, orange prisms, melting at 137°.

The disazo-compound crystallises from benzene in long, floccy, violet needles, with a melting point of 238°.

It was further found that the disazo-compound was easily formed from either mono-azo-compound by treatment with diazobenzene chloride. Also, when a sufficient amount of solvent is present, the disazo-compound produced, remains dissolved in the cold, which explains the apparent non-formation of this body in the first reaction mentioned above. The violet disazo-body was boiled with acetic acid for a long time and a crystalline brown-yellow substance obtained therefrom, melting, after crystallisation from benzene, at 287°. On reduction with zinc dust and hydrochloric acid the latter substance was converted into a eurdiodine, which fact, in conjunction with the analytical figures, leaves no room for doubt that the brown-yellow substance is an azo-azine of the following constitution:—

—E. B.

*Synthesis of Indigo from Monobromacetanilide.* W. Flimm. Ber. 23, 57—60.

THE action of caustic alkalis on bromacetanilide differs according to the condition in which the two bodies react on each other. Thus aqueous potash causes the absolute breaking up of the molecule with formation of carbamine. By using alcoholic potash Abenius obtained diphenyldiketopiperazine. Again, if the calculated quantity of sodium be added to an absolute alcoholic solution of bromacetanilide, after some time there separates a thick yellowish oil, ethoxyacetanilide,  $C_6H_5NH(COCH_2OC_2H_5)$ .

Finally, the author has discovered that when a small quantity of monobromacetanilide is mixed with an equal weight of dry caustic potash, and the mixture rapidly heated to a high temperature until a homogeneous reddish-brown melt is obtained, then on dissolving the latter in water and a little ammonia, a greenish solution is obtained, which rapidly changes to blue and after a short time a blue colouring matter separates. If the melt be dissolved in dilute acid and ferric chloride added, indigo separates out at once. The fact of its really being indigo was proved by a great variety of characteristic reactions, including also an examination of the absorption spectrum, which absolutely agreed with that of indigo. The yield is only 4 per cent.

The chemical reactions whereby the formation of indigo is in this case brought about, are explained thus. Starting from bromacetanilide, indoxyl—

is first produced, or possibly a pseudo indoxyl—

and the latter is then oxidised to indigo. The syntheses of this colouring matter from *o*-amidoacetophenone which is brominated in the side-chain is a well known one. Now this substance is isomeric with bromoacetanilide. It is, however, not likely that the production of indigo from the latter body is preceded by the formation of the former, since it is evident that the first reaction that will take place is the splitting off of hydrobromic acid.

Attempts to obtain dyes similar to indigo from bromoaceto-*α*- or *β*-naphthalide or from bromoacetyldiphenylamine or from bromoacetoorthotoluide were unsuccessful. From bromoaceto-*para*-toluide, however, dimethyl indigo was readily prepared. In its outward properties the latter cannot be distinguished from indigo. By distilling it with excess of caustic alkali, pure *para*-toluidine distils over. The reason why indigo is not produced from the orthotoluide is evidently due to the fact that a methyl group occupies the ortho position in the benzene nucleus. The carbonyl group is consequently unable to enter at this point. This fact the author considers a further proof of the groups CO and NH in indigo being attached to adjoining carbon atoms. Di-bromoacetanilide when strongly heated with caustic potash or alcoholic potash yields no indigo, but considerable quantities of carbamine according to the equation—

—A. R.

*On α-Naphthylamine-ε-Disulphonic Acid.* G. Schnltz.  
Ber. 23, 77.

THE preparation of *α*-naphthylamine-*ε*-disulphonic acid has been patented by the three firms: the "Actiengesellschaft für Anilin fabrikation" (Ger. Pat. 45,776), "Ewer and Piek" (Ger. Pat. E. 2318), and the "Badische" (Ger. Pat. B. 9514). In each patent the method employed for the production of the above acid is identical, consisting in nitrating *α*-*β*-naphthalenedisulphonic acid and then reducing the resulting *α*-nitro-*α*-*β*-naphthalenedisulphonic acid. The only appreciable difference between the above three patents is that the first-named firm employs a mixture of *α*-*α*- with *α*-*β*-naphthalenedisulphonic acid, thereby finally obtaining both *α*-naphthylamine *δ*- as well as *ε*-disulphonic acid, about the same quantity of each being produced.

Besides these acids other sulphonic acids are obtained as by-products in the above processes, and amongst them the author was able to identify *β*-naphthylaminedisulphonic acid.

—A. R.

*The Euxanthone Group.* C. Graebe. Annalen, 254,  
265—303.

THESE compounds are derivatives of triphenylene-ketone oxide (xanthone) for which the subjoined constitutional formula is regarded by the author as definitely established:—

the numerals indicating the order of designation of the substituting groups, which he has adopted for the formulation of the derivatives.

The compounds are of special technical interest from the occurrence of a typical representative (Euxanthic Acid) in the well-known Indian Yellow or Purree. This colouring matter is a urinary secretion of cows fed upon mango leaves, and exclusively produced by a sect of the Gwalis in the Monghyr district of Western India. Upon this peculiar process of manufacture the author quotes in full

a report by T. N. Mukharji to the India Office of August 1883 (see also Jour. Soc. Arts, 32, 16). The Purree separates spontaneously from the urine, but the separation is promoted by applying heat. Each cow, on this diet, yields on the average 3.4 litres of urine daily, from which 50—60 grms. of the Purree are obtained. The physiology of the process has not been as yet elucidated. Euxanthic acid, the chief constituent of the yellow, has been shown by Kostanecki (Ber. 19, 2918; this Journal, 1887, 507) to be formed from euxanthone, in the passage of this compound through animal organisms; but investigation of mango leaves have so far failed to reveal the presence of any constituent resembling euxanthone.

A selected specimen of Purree gave the following results on analysis:—

Euxanthic acid.....	51.0
Silica and alumina.....	1.5
Magnesium.....	4.2
Calcium.....	3.4
Water and volatile constituents (160°—170° C.)	39.0
	99.1

The firm of MM. Lefranc and Cie (Paris) supply several varieties of Purree, designated in order of inferiority by letters from A to G, the corresponding prices varying from 300 frs. to 50 frs. per kilo. Subjoined are the results of the author's analyses of these products (Compare Ber. 16, 864):—

	A.	B.	C.	D.	G.
Euxanthic acid .....	72.3	70.9	64.3	59.3	53.34
Euxanthone.....	0.0	1.1	2.8	7.4	31.0
Mg .....	5.4	4.9	4.9	4.6	3.7
Ca.....	1.8	2.4	2.6	3.3	3.7

From these analyses it is evident that euxanthone is present in the inferior sorts only, in which also the ratio Ca : Mg is relatively high.

*Euxanthic Acid* is easily prepared in the pure state by first digesting a Purree of good quality with dilute hydrochloric acid and dissolving out the acid from the residue by treatment with ammonium carbonate. The solution is filtered and treated with an acid, when the compound separates. It forms two classes of salts,  $\text{C}_{19}\text{H}_{16}\text{O}_{11}\text{M}'$  and  $\text{C}_{19}\text{H}_{16}\text{O}_{11}\text{M}'_2$ . It is a condensed derivative of euxanthone and glycuronic acid, containing the COOH group of the latter unaltered, but only one of the OH groups of the euxanthone. The author proposes the subjoined constitutional formula (assuming Schmiedeberg and Meyer's formula for glycuronic acid)—

the glycuronic acid, when split off (by hydrolysis) contains the group  $\text{CH}(\text{OH})_2$  which is at once resolved into  $\text{COH} + \text{H}_2\text{O}$ , and this explains the fact that the hydrolysis of the euxanthic acid does not appear to involve combination with  $\text{H}_2\text{O}$ .

*Xanthone* (diphenyleneketone oxide) is the chief product (45 per cent.) of the action of heat upon salol, phenylsalicylic acid being first formed, then dehydrated.

Its characteristic reactions are (1) reduction to methylenediphenyl oxide by heating with zinc dust; and (2) conversion into dioxybenzophenone by heating with alcoholic potash at 180°, by which its constitution is established.

*Euxanthone* fused with potassium hydrate yields resorcinol in addition to quinol (hydroquinone), the two phenols in

approximately equal quantity, whence the author deduces the annexed constitutional formula—

Euxanthone, identical in every respect with that obtained from Indian Yellow, was obtained synthetically by heating  $\beta$ -resoreic acid and quinol carboxylic acid together with acetic anhydride.

*Euxanthonic Acid* was obtained by heating euxanthone with three times its weight of caustic potash and some water, so that gradually the temperature is brought up to  $260^{\circ}$ — $270^{\circ}$ . Euxanthonic acid fuses at  $200^{\circ}$ — $202^{\circ}$ , losing water, and gradually forming euxanthone.

The paper concludes with a tabular résumé of all the members of the group at present investigated.—C. F. C.

*Studies on the Constitution of the Tri-derivatives of Naphthalene. No. 1. The Constitution of Betanaphthol- and Betanaphthylaminedisulphonic Acids R and G. Naphthalenemetadisulphonic Acid.* H. E. Armstrong and W. P. Wynne. Proc. Chem. Soc. 1890 (77), 11—15.

$\beta$ -NAPHTHOLDISULPHONIC acid G (Gelb), like the "Bayer" modification of  $\beta$ -naphtholmonosulphonic acid, interacts but slowly with diazo salts, while the corresponding  $\beta$ -naphthylaminedisulphonic acid, like the "Badische" modification of  $\beta$ -naphthylaminemonosulphonic acid, is incapable of forming azo dyes with the majority of diazo salts.

In converting the dichloronaphthalenes into sulphonic acids, the authors noticed that isomeric changes occurred in several instances (Proc. Chem. Soc. 1889, 52, 120). As a contribution to a study of the precise course of the change in sulphonation, it seemed desirable to make a comparative study of the influence exercised by radicles such as Cl, OH, and  $\text{NH}_2$  on the formation of disulphonic acids.

With regard to the dichloronaphthalenes, see Proc. Chem. Soc. 1888, 104. In the case of the trichloronaphthalenes, no fewer than 14 are possible, which will ultimately serve as reference compounds for tri-derivatives of naphthalene. It is very necessary to characterise each compound, owing to the close similarity which obtains between many of the isomerides; no fewer than four, for example, melt at nearly the same temperature, about  $90^{\circ}$ — $92^{\circ}$ .

*Constitution of the  $\beta$ -naphthylaminedisulphonic Acid R.* —Duisberg and Pfitzinger inferred that this acid was derived from the  $\alpha$ -naphthalenedisulphonic acid of Ebert and Merz, as the disulphonic acid obtained from it on displacing the  $\text{NH}_2$  group by v. Bayer's hydrazine process gave the dihydroxynaphthalene corresponding to the  $\alpha$ -acid on fusion with potash. The authors thought it desirable to amplify the evidence in order to meet the possible objection that isomeric change may occur during the fusion, as in the case of benzene-derivatives. They find on directly comparing the disulphonic acid with the Ebert and Merz  $\alpha$ -acid that the two behave alike.

By adopting Sandmeyer's method, the  $\alpha$ -acid was converted into a chlorodisulphonic acid, and this on distillation with  $\text{PCl}_5$  yielded the corresponding trichloronaphthalene.

*Constitution of  $\beta$ -naphthylaminedisulphonic Acid G.* —A quantity of this acid was converted into the naphthalenedisulphonic acid by the hydrazine method and a new acid was thus obtained, which was proved to be the metadisulphonic acid of naphthalene. The relative position of the sulphonic radicles being thus determined, their positions relatively to the  $\beta$ - $\text{NH}_2$  radicle may be inferred from the facts that the hydroxy-G-acid is obtained as direct sulphonation-product of the Bayer modification of  $\beta$ -naphthol-

sulphonic acid, and that it yields, as Caro first proved, the isomeric Schaeffer acid when reduced by sodium amalgam. Although the sulphonic acids are usually reducible to naphthalene in the manner first pointed out by Otto in the case of naphthalene- $\alpha$ -sulphonic acid, the  $\beta$ -sulphonic derivatives are far less readily affected; the  $\text{NH}_2$  radicle also exercises a special protecting influence in many cases. Superposing the various results, the constitution of the G-acids is shown to be as follows:—

The G-acid is convertible by Sandmeyer's method into a chlorodisulphonic acid, the chloride of which crystallises from benzene in long radiate needles, melting at  $170^{\circ}$ ; this is converted by  $\text{PCl}_5$  into a trichloronaphthalene which crystallises in very slender needles melting at  $113^{\circ}$ , identical with that obtained by Alén (Ber. Referate, 1884, 437) from an  $\alpha$ -nitro acid prepared by nitrating the chloride of the  $\beta$ -disulphonic acid of Ebert and Merz. This result confirms the conclusion above arrived at, as of the three possible formulæ of Alén's acid:—

II. and III. are excluded by the fact that the trichloronaphthalene corresponding to III. melts at  $90^{\circ}$ — $91^{\circ}$  (*vide supra*), and that corresponding to II. also at about the same temperature (Proc. Chem. Soc. 1889, 52).

The results now obtained show that, as in the case of the Bayer and Badische monosulphonic acids, the action of diazo-salts on the G-disulphonic acids is either retarded or prevented by the "protecting influence" exercised by an  $\alpha$ -1'-sulphonic group.

The properties of the five known naphthalenedisulphonic acids are summarised in the appended table:—

(See top of next page.)

*Studies on the Constitution of Tri-derivatives of Naphthalene. No. 2.  $\alpha$ -Amido-1:3'-Naphthalenedisulphonic Acid.* H. E. Armstrong and W. P. Wynne. Proc. Chem. Soc. 1890 (77), 15—16.

THE 1:3'-naphthalene- $\alpha$ - $\beta$ -disulphonic acid (Proc. Chem. Soc. 1886, 231; 1889, 10) has acquired considerable interest on account of the peculiar behaviour of the amido- and corresponding hydroxy-acid prepared from it and the dye-stuffs which the amido-acid affords (Bernthsen, Ber. 22, 3327). This amido-acid has been patented by the Aetiengesellschaft für Anilinfabrikation, in whose laboratory it was first prepared by Andresen (Schultz, Ber. 23, 77) by nitrating the  $\alpha$ - $\beta$ -disulphonic acid above referred to, and reducing the nitro-derivative. Technically, it has become known as  $\alpha$ -naphthylamine- $\epsilon$ -disulphonic acid.

The authors first satisfied themselves that the amido-acid had been prepared from their  $\alpha$ - $\beta$ -disulphonic acid by reducing it by the hydrazine method; the acid obtained gave a sulpho-chloride, melting at  $127^{\circ}$ , and a dichloronaphthalene, melting at  $48^{\circ}$ .

The corresponding chlorodisulphonic acid was then prepared by Sandmeyer's method; the disulphochloride of this acid melts at  $110^\circ$ ; on distillation with  $PCl_5$  it is converted into a trichloronaphthalene, which appears to be dimorphous, crystallising from alcohol either in long slender needles melting at  $87^\circ$ , or in large flat prisms melting at  $90^\circ$ .

As the amido-acid is known to yield  $\alpha$ -naphthylamine when deprived of its sulphonic groups, there are only three formulae which can be assigned to it:—

Formula I. is precluded, as the corresponding trichloronaphthalene melts at  $78^\circ$ ; formula II. is likewise precluded, as the corresponding trichloronaphthalene (*vide infra*) melts at  $66^\circ$  and  $56^\circ$ ; formula III. therefore expresses the constitution of the acid. This result is confirmed by the conclusions arrived at by Bernthsen, who finds that the corresponding hydroxy-acid exhibits the behaviour of the 1:1'-hydroxysulphonic acid, readily yielding a naphthalene-sulphonelactone-sulphonic acid.

*Studies on the Constitution of the Tri-derivatives of Naphthalene. No. 3.  $\alpha$ -naphthylaminedisulphonic Acid Dahl No. III. The Constitution of Naphthol-yellow S.* H. E. Armstrong and W. P. Wynne. *Proc. Chem. Soc.* 1890 (77), 16—18.

It is well known that when  $\alpha$ -naphthol is sulphonated by excess of sulphuric acid, it is readily converted into acids capable of yielding naphthol-yellow S, a most valuable dyestuff, the sulphonic acid of dinitro- $\alpha$ -naphthol, on treatment with nitric acid; although it is known that the Yellow is a heteronuclear derivative and that the sulphonic group is in a  $\beta$ -position, inasmuch as it yields 1:2:4-sulphophthalic acid on oxidation, the position of this group has not hitherto been determined. With the object of ascertaining the constitution of the yellow, the authors have examined the  $\alpha$ -naphthylaminedisulphonic acid No. III.

(Dahl's acid), prepared by sulphonating naphthionic acid with 35 per cent. anhydrosulphuric acid at a temperature not exceeding  $30^\circ$ , this acid being very readily converted into the yellow by diazotising and then heating with nitric acid.

When reduced by the hydrazine method, the Dahl No. III acid is found to yield the authors' 1:3'-naphthalene disulphonic acid; the sulphochloride actually prepared from the acid melted at  $127^\circ$ , and the corresponding dichloronaphthalene at  $49^\circ$ . Taking into account the fact that naphthol-yellow S is a heteronuclear  $\beta$ -sulphonic derivative, this result is alone sufficient to determine the constitution of the yellow and of the amido-acid, thus—

The chlorodisulphonic acid prepared from the Dahl acid yields a sulphochloride very soluble in benzene, from which it crystallises in small prisms; it separates from petroleum spirit in rosettes of small, apparently rectangular prisms, melting at  $107^\circ$ . The corresponding trichloronaphthalene affords a remarkable case of dimorphism: it is sparingly soluble in hot alcohol, from which it crystallises in slender needles, melting at  $66^\circ$ ; if the melting point be redetermined as soon as solidification has taken place, it is found to be  $56^\circ$ , but if determined after a longer interval,  $66^\circ$ , as in the first instance. This trichloronaphthalene should be identical with that prepared by Widman from dichloronaphthalene- $\beta$ -sulphonic chloride, though the authors have shown to be a derivative of 1:4-dichloronaphthalene, but Widman's product is said to melt at  $56^\circ$ ; the authors find, however, on preparing it according to Widman's direction,

that it also melts at 66° or 56°. By nitrating 1:3'- $\eta$ -dichloronaphthalene, Cleve obtained a nitrodichloronaphthalene, yielding a trichloronaphthalene, melting at 65°; the authors' observations show that this is in reality identical with the Widman trichloronaphthalene, and, therefore, that the behaviour of 1:3'-dichloronaphthalene on nitration is perfectly "normal," and strictly comparable with that of both  $\alpha$ - and  $\beta$ -monochloronaphthalene.

By sulphonating 1:4-chloronaphthalenesulphonic acid in the form of potassium salt by means of the theoretical proportion of sulphuric anhydride employed as 20 per cent. anhydrosulphuric acid at 100°, the authors have obtained a chlorodisulphonic acid identical with that prepared from the Dahl amido acid: showing that the  $\alpha$ -chloro-,  $\alpha$ -amido-, and  $\alpha$ -hydroxy-monosulphonic compounds behave similarly on further sulphonation; but it remains to be ascertained whether the series of changes leading up to the production of the final stable compounds is identical in the several cases.

*New Colouring Matters.* J. Soc. Dyers and Colourists, 1890, 32.

#### I.—DYES INTENDED PRINCIPALLY FOR WOOL AND SILK.

"*Clayton Cloth Red*" is the Ammonium salt of Naphthol primuline. The commercial product is a dark red granular powder, which dissolves in hot water with a clear scarlet colour. Dilute sulphuric acid completely separates the colour as an orange precipitate. It is also completely precipitated by excess of caustic soda. Stannite of soda, or hyposulphite of soda, reduces the colour, producing a yellow solution. Cotton boiled in this, passed through a bath of nitrous acid, and then into an alkaline solution of  $\beta$ -naphthol, is dyed red. *Clayton cloth red* is dyed on wool in an acid bath, and produces a full blue shade of scarlet, which bleeds slightly when milled with soap, but does not go into the white. Dyed on wool, it gives the following reactions: Boiled with dilute sulphuric acid the colour is not changed; by ammonia it is partly removed. Concentrated sulphuric acid turns the fibre dark violet.

*Auroline* is Tetra-nitro-phenolphthalein. The commercial product is a yellow paste, which dissolves in water with an orange-red colour, which is rendered clearer and somewhat darker on the addition of caustic soda. Dilute sulphuric acid completely precipitates the dye. The most characteristic reaction is that with stannite of soda, in presence of excess of caustic soda, by which the yellow colour of the solution rapidly changes to an intense indigo blue. The dried paste gives, with strong sulphuric acid, a brown-orange solution. *Auroline* is dyed on wool in a bath acidulated with acetic acid, and produces orange-yellow shades resembling those obtained with Tartrazine. The colours are fast to milling, and do not bleed into the white. Dyed on wool, *Auroline* gives the following reactions: Boiled with dilute sulphuric acid, the colour goes, but is restored by ammonia. Stannite of soda and caustic soda turn the fibre blue. By concentrated sulphuric acid the fibre is turned somewhat redder.

#### II.—DYE INTENDED PRINCIPALLY FOR COTTON.

*Thiazol Yellow* dissolves in water with a yellow colour. Dilute sulphuric acid produces an orange precipitate having a yellow solution. Caustic soda produces a scarlet precipitate, which dissolves on boiling. By stannite of soda the orange colour of the hot alkaline solution is not affected. Calico is dyed with 12 per cent. of the colour, 5 per cent. of common salt, 5 per cent. of sodium phosphate, and 2 per cent. of soap, a bright canary yellow, which bleeds very slightly to soap water and does not go into the white. Dyed on cotton, *Thiazol yellow* gives the following reactions: Boiled with dilute sulphuric acid, the fibre is turned orange, with caustic soda a blue shade of red. Stannite of soda produces an intense orange; strong sulphuric acid no change.

#### PATENTS.

*Improvements in or connected with the Manufacture and Production of Unsymmetrical Acid Green.* B. Willecox, London. From "The Farbenfabriken vormals Fr. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 1046, January 19, 1889. 6d.

A PROCESS for the production of new acid green dyestuffs by condensing benzaldehyde, dimethylaniline and methylbenzyl-aniline in molecular proportions in presence of a dehydrating agent. The unsymmetrically substituted di-amido-triphenyl-methane derivative thus obtained is sulphonated and the leucosulphonic acid on oxidation yields a green dyestuff. The working details are as follows: About 22 kilos. of sulphuric acid of 66 per cent. strength are gradually poured into an enamelled vessel cooled externally containing 12.1 kilos. of dimethylaniline and 19.7 kilos. of methylbenzyl-aniline and 10.6 kilos. of benzaldehyde are then slowly added at the ordinary temperature. The mixture is afterwards heated to 120°—130° C. and kept at this temperature for some hours. The melt is dissolved in water when a small quantity of symmetrical dimethyl-dibenzyl-diamido-triphenyl methane which is formed separates out. The tri-methylbenzyl-diamido-triphenylmethane is precipitated by adding sodium sulphate solution, leaving the small quantity of tetra-methyl-diamidotriphenylmethane formed in solution. The precipitate is boiled up several times with water, and forms a resinous mass of a pale-green colour. It is dissolved in cooled sulphuric acid (about five parts by weight) containing 20 per cent. of SO<sub>3</sub> and allowed to stand at the ordinary temperature until a sample dissolves in dilute alkali to a clear solution. The melt is then poured into water, the sulphonic acid converted into its sodium salt and oxidised with the calculated quantities of lead peroxide and dilute sulphuric acid. 10 kilos. of the sodium salt are dissolved in about 250 litres of water. The bluish-green solution of the dyestuff which results is filtered from the sulphate of lead and evaporated to dryness. The dyestuff obtained gives a bluish-green shade, and dyes more slowly on wool than do the ordinary acid greens. Different shades are obtained by using other tertiary amines, and in place of benzaldehyde, *m*-nitrobenzaldehyde may be used (Eng. Pat. 15,329, of 1885).—T. A. L.

*A New or Improved Manufacture of Para-Amido-Phenol Ethers.* B. Willecox, London. From "The Farbenfabriken vormals Fr. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 1771, January 31, 1889. 6d.

See under XX., page 324.

*A New Extract and its Utilisation as a Dye, Ink, Stain, Tanning Liquor, and the like.* E. Brauser, London, and J. H. Knowles, Hull. Eng. Pat. 2360, February 9, 1889. 4d.

THE fibrous plant or material known as "*Bauhinia Vahlä*" is boiled in an alkaline solution, and afterwards squeezed by passing through rollers by which a colouring matter is extracted. The solution can be concentrated and the colouring matter may, according to the specification, be employed for the variety of purposes mentioned in the title.—T. A. L.

*The Manufacture or Production of a Colouring Matter or Dyestuff from Phenolphthalein.* C. Dreyfus, H. Bull, and J. Hall, Manchester. Eng. Pat. 3441, February 26, 1889. 6d.

YELLOW dyestuffs are obtained by the action of nitric acid on phenolphthalein dissolved in sulphuric acid or glacial acetic acid or in a mixture of the two. A dinitro compound melting at 196° C. containing 6.91 per cent. of nitrogen (calculated 6.86 per cent.) and a tetra-nitro-derivative melting at 244.5° C. containing 10.89 per cent. of nitrogen (calculated for C<sub>20</sub>H<sub>10</sub>N<sub>4</sub>O<sub>12</sub>, N = 11.2 per cent.) have been obtained. The salts of the latter are soluble in water and dye animal fibres deep yellow from a neutral bath.—T. A. L.

*Improvements in the Manufacture or Production of Indulines or Induline-like Dyestuffs.* B. Willeox, London. From "The Farbenfabriken vormals Fr. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 3529, February 27, 1889. 6d.

THE specification describes several methods for the production of indulines soluble in water. Most of these consist in fusing spirit-soluble dyestuffs technically known as nigrosine, aniline black, and safranine with *p*-phenylenediamine at temperatures about 190° C. until the melt is completely soluble in dilute hydrochloric acid. The whole melt is then so dissolved and the dyestuff salted out. Toluylenediamine may be substituted for the phenylenediamine. Azobenzene, azotoluene, azoxy- and hydrazo-compounds also yield soluble dyestuffs when heated with *p*-phenylenediamine in presence of sal-ammoniac. Greenish-blue to blue-black induline-like dyestuffs are obtained by oxidising *m*- and *p*-phenylenediamines with weak organic oxidising agents such as chloranile, dichloronaphthoquinone, naphthoquinone and naphthoquinone chlorimide. Aniline hydrochloride and its homologues when heated to 120°, and finally to 165° C. with *m*- or *p*-nitraniline, together with chloride of iron and benzoic acid or ammonium chloride, also form similar colours. The aniline may be replaced by a secondary or tertiary amine, a good result being obtained if a small quantity of aniline or toluidine hydrochloride be added to the melt.—T. A. L.

*Improved Manufacture of Green and Bluish-Green Colouring Matters.* O. Inray, London. From "The Farbwerke vormals Meister, Lucius and Brüning," Höchst, Germany. Eng. Pat. 5549, April 1, 1889. 6d.

THIS is an extension of Eng. Pat. 12,796 of 1888 (this Journal, 1889, 701) and describes the preparation of the *m*-hydroxybenzoic bases of the malachite green series of which *m*-hydroxytrimethylbenzylidiamidotriphenylmethane—

may serve as a type. These bodies may be obtained as already described by the action of nitrous acid on the corresponding amido compounds, or with regard to the compound here named by condensing equal molecular parts of *m*-hydroxybenzaldehyde, dimethylaniline, and methylbenzylaniline. The products are converted into sulphonic acids and on oxidation yield colouring matters which form copper-red powders of metallic lustre easily soluble in water. They dye wool and silk bluish-green shades fast to soap and light.—T. A. L.

*Improvements in the Manufacture and Production of Colouring Matters for Dyeing and Printing.* C. Dreyfus, Clayton, Manchester. Eng. Pat. 18,901, November 29, 1889. 4d.

DEHYDROTHIOPARATOLUIDINE sulphonic acid (see this Journal, 1889, 980; and 1890, 49) is converted into its diazo compound and combined with  $\beta$ -naphthol in an alkaline solution. The colouring matter after precipitation with an acid is converted into the ammonium salt. It dyes wool from an acid bath fast to fulling and can be used for printing cotton when applied with basic sulphate of alumina, the goods being subsequently steamed.—T. A. L.

#### ERRATUM.

In February issue, 1890, page 173, col. 1, 31 lines from the top, for "toluidine sulphate" read "tolidine sulphate."

Also *ibid*, same page and column, 8 lines from the bottom, for "diamido-azobenzene" read "diamido-azoxybenzene."

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

### PATENTS.

*A New Composition, forming a sort of Artificial Silk, for the Production of Threads or Filaments and Films, and for Coating Threads, Fabrics, or Objects, and Apparatus Employed in the Manufacture of said Composition.* I. H. du Vivier, Paris, France. Eng. Pat. 2570, February 13, 1889. 8d.

THE basis of this invention is a solution of tri-nitrocellulose in glacial acetic acid. The tri-nitrocellulose is prepared as follows. Cotton is steeped for three days, with occasional stirring, in a cold solution of caustic soda and ammonia. It is then washed, dried and carded. The nitrating bath is made by mixing 20 parts of potassium nitrate with 30 parts of sulphuric acid at 66° B. The temperature of the bath should be about 85° C. One part of cotton is introduced in small tufts, and the vessel containing it is revolved for five or six minutes, when the nitrated cotton is thoroughly washed and dried. Three solutions are prepared: (1) a 12·5 per cent. solution of gutta-percha in carbon disulphide; (2) a 5 per cent. solution of isinglass in glacial acetic acid; (3) a 7 per cent. solution of the tri-nitrocellulose in glacial acetic acid. These solutions are mixed together so that the mixture contains 4 parts of tri-nitrocellulose, 1 part of isinglass, and  $\frac{1}{2}$  part of gutta-percha; small quantities of glycerin and castor oil are then added and the whole kneaded together. The resulting viscous fluid is filtered and forced through narrow orifices under water. The thread so produced is first led into a bath of soda to remove the acetic acid, then into one of albumen, then into one of bichloride of mercury, and from thence into an atmosphere of carbon dioxide. In order to lessen its combustibility it is treated with ammonia and sulphate of alumina. The necessary apparatus is fully described. (Compare this Journal, 1889, 539.)—E. J. B.

*Improvements in Apparatus for the Manufacture of Textile Threads from Viscous or Semi-fluid Matters.* I. H. du Vivier, Paris, France. Eng. Pat. 2571, February 13, 1889. 8d.

THIS specification relates to apparatus for forming the threads described in Eng. Pat. 2570 (preceding abstract). Also to apparatus for drawing the threads through baths, drying and winding on bobbins, &c.—E. J. B.

*An Improved Textile Fabric or Material adapted to be worn next to the Skin.* C. I. Schott, Bradford. Eng. Pat. 2619, February 14, 1889. 4d.

THE fabric is formed of a mixture of hard spun yarn with a soft spun yarn, the manufacture being so conducted that the former projects in kinks beyond the surface of the fabric. Such articles produce a slight exciting action upon the skin without being irritating.—E. J. B.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*Notes on Mordants applicable in Wool-Dyeing.* (From the Dyeing Department of the Yorkshire College.) W. M. Gardner. J. Soc. Dyers and Colourists, 1890, 37—40.

WHEN dyeing wool with what have been termed the "polygenetic" colouring matters, it is necessary to use as mordant some metallic compound. The number of such mordants in practical use at the present time is very limited, some half-dozen completing the list.

*Bichromate of potash* (or soda) is probably the most largely used, but *aluminium sulphate* and *ferrous sulphate* are also employed for this purpose in enormous quantities. Somewhat less important are *stannous chloride* and *copper sulphate*, while a few other metallic salts find application in special cases.

From a purely chemical standpoint the few substances enumerated above possess no qualifications to act as mordants for wool which do not also characterise a large number of metallic compounds. Chromium, iron, copper, aluminium, and tin combine, *e.g.*, with alizarin, each metal producing a different colour. We should expect, therefore, by using compounds of other metals as mordants that still other colours would be obtained from the same dyestuffs.

The introduction of a successful new mordant is of great practical importance, and since there is the possibility of it yielding a new shade with many of the class of dyestuffs above referred to, it may prove of equal value to the introduction of several new colouring matters. The latter are being continually brought forward, but of late years few, if any, new metals have been used as mordants in wool-dyeing, although several new compounds of the metals at present in use have been introduced into the trade.

The question may here occur, are the particular compounds of chromium, iron, &c., now used, the best possible form in which to apply those metals? It is thought that for general purposes they may be considered satisfactory, but in many cases a distinct advantage would be gained by using other salts.

With respect to chromium, it is usually employed as a mordant for wool in the form of potassium or sodium bichromate. This being a strong oxidising agent it may, under certain circumstances, oxidise the wool or the colouring matter employed, and more or less destroy it. Hence the desirability of a chromium salt not possessing this defect. In view of this, those chromium salts in which the chromium forms the base—*e.g.*, chromic sulphate, chrome alum, &c., are naturally turned to. The last-named salt has long ago been proposed as an efficient substitute for potassium bichromate. As a by-product in the manufacture of alizarin it is comparatively cheap, and one might have expected that it would frequently be employed in practice, and this no doubt would be the case if it had been found superior to bichromate of potash.

It is well known that chromium sulphate, acetate, &c., are not satisfactorily fixed upon cotton by the methods which are used with the corresponding aluminium salts, and it would not be surprising if chromium and aluminium salts showed similar differences when used as mordants for wool. From experiments the author has made, however, it appears that chrome alum may be applied in the same manner as common alum—*i.e.*, with an addition of cream of tartar. But whereas with 1 molecule common alum an addition of 4 molecules cream of tartar is sufficient, with the molecule of chrome alum it is found necessary to use 12—18 molecules cream of tartar. The great expense of this large addition of cream of tartar is probably the reason why chrome alum is not practically employed.

A *Fluoride of chromium* ( $\text{CrF}_3 \cdot 4 \text{H}_2\text{O}$ ) has recently been put upon the market under the name of "*fluorchrome*." This substance, like chrome alum and oxalic acid, is a non-oxidising mordant, and also gives the green ( $\text{Cr}_2\text{O}_3$ ) mordanted wool, but attempts to obtain with it such full bright shades as with the use of potassium bichromate and tartaric acid were not successful. It appears also to give somewhat uneven shades, but possibly these defects may be overcome on further trials. The defects noticed are possibly due to the hydrofluoric acid liberated in the mordanting operation. "*Fluorchrome*" is considerably more expensive than chrome alum and oxalic acid.

Compared with other metals, chromium appears to be the most generally useful as a mordant for wool, since it gives both red, yellow, and blue colours with different colouring matters, so that by using a mixture of colouring matters a very large variety of compound shades may be obtained. Of the various chromium salts with which experiments have been made, potassium or sodium bichromate is the best for general use, being cheap, easily applied, and apparently not materially affecting the fibre, although the last point is

much questioned. Experiments on this latter point are in progress.

The shades produced by chromium mordant are, as a rule, dark, brilliant, and very fast against light and alkalis.

With respect to the *aluminium* mordants, it is worthy of remark that for most purposes the long-cherished alum is gradually giving way to the more rational aluminium sulphate, which can now be obtained sufficiently free from iron, and which, considering the percentage of aluminium it contains, is much cheaper.

Cream of tartar is the best assistant to use in conjunction with aluminium sulphate or alum for most colouring matters, but in some cases oxalic acid or binoxalate of potash gives much better results.

The chief use of the aluminium mordant is for the production of such light colours as cannot be obtained with chromium or iron. Speaking generally, the colours are more fugitive to light and to alkalis than those of chromium, copper, or iron, although not so easily affected as the tin compounds. Aluminium sulphate and alum crystals (potassium or ammonium alum) are the only salts of the metal which are used as mordants for wool.

The usual iron mordant is *ferrous sulphate*. In experimenting with this mordant it has been found that in almost every case an addition of oxalic acid gives much better results than the usual assistant—cream of tartar. It is also much cheaper. With many colouring matters some lime salt must be added to the dye-bath when using this mordant.

As to the comparative behaviour of *ferrous* and *ferrie* sulphate as mordants in wool dyeing, experiments showed that the two salts behave very similarly with respect to the assistants required, best proportions, &c., as well as in regard to the shade produced. Still the ferrie salt is sometimes to be preferred to the usual ferrous sulphate.

The remarkable action of an addition of oxalic acid when mordanting with ferrous sulphate has been already noticed, and this assistant has an equally good effect when ferrie sulphate is employed.

An amount of ferrie sulphate equivalent to from 4—10 per cent.  $\text{FeSO}_4 \cdot 7 \text{H}_2\text{O}$ , with an addition of 2—5 per cent. oxalic acid, should be used, the best amount varying within those limits according to the particular dyestuff and the percentage of it employed. As with ferrous sulphate, an addition of chalk or calcium acetate to the dye-bath is often very beneficial.

A most noteworthy point in connexion with the iron mordant, both ferrous and ferrie, is that the concentration of the mordant-bath has in many cases a very marked influence upon the shade produced. Good results are only obtained when using comparatively dilute solutions, *e.g.*, 0.3—0.6 gm.  $\text{FeSO}_4$  per litre; that is to say, in order to have the best percentage of mordant (6—9 per cent.  $\text{FeSO}_4$  and 3—4 per cent. oxalic acid), no more than 5—10 grms. of wool should be mordanted per litre of water.

If the solutions are concentrated—*e.g.*, 1.5—2 grms.  $\text{FeSO}_4$  per litre of water—it may happen that no colour is produced at all, or at most a dirty grey is obtained. In our experiments 1 litre of water and 10 grms. of wool were employed, but in practice the proportion of water to wool would be much less than this. Much more concentrated solutions would therefore be employed if the percentages given above were adhered to, and in order to prevent the injurious effect of too great concentration the amounts must be modified.

*Stannous chloride* ( $\text{SnCl}_2$ ) is the usual tin mordant, but the more acid *stannic chloride* ( $\text{SnCl}_4$ ) is sometimes useful. The great disadvantage of the tin mordant is that it has a very injurious action upon the wool fibre, tending to destroy its milling properties, and making it rough and harsh to the feel. This action is less marked with the stannic than with the stannous salt, the strong reducing action of the latter possibly having an influence. There is no doubt that some new mordant which would give as bright shades as tin, but without this very serious defect, would be of great value.

As is the case with aluminium mordant, the best assistant to use with tin mordant varies with the colouring matter employed. In some cases cream of tartar, in others oxalic acid, gives the best result.

The copper mordants are not of first-rate importance. The cuprous salts are too unstable for use as wool mordants, and cupric sulphate is the only salt employed for the purpose. With most colouring matters copper sulphate produces very similar shades to potassium bichromate, and as the latter is much cheaper, it is naturally employed. Usually, cream of tartar is a better assistant than oxalic acid or binoxalate of potash with the copper mordant.

A general consideration of the metals already in use as mordants shows that in some cases cream of tartar is the best assistant to use, while in others oxalic acid or binoxalate of potash is much to be preferred. It would naturally be expected that when a certain assistant proves to be the best with any given mordant, that it would be so, irrespective of the colouring matter employed. Experiment, however, proves that this is not the case.

The new mordants considered in this paper are the sulphates of manganese, nickel, cobalt, and uranium. The first three of these, together with iron, form a natural group possessing similar properties. They all form compounds more or less analogous to the ferrous and ferric salts, and it appeared interesting to determine by experiment whether the behaviour of their salts as mordants showed a like similarity. Manganese being a cheap product, it would be within the range of practical application if it was found to give useful colours, and even the other metals, though more expensive, might still be used if they produced colours possessing specially useful properties.

A careful series of experiments was made with these mordants in conjunction with anthrapurpurin, the effect of various amounts of mordant, assistants to mordant-bath or dye-bath, methods of dyeing, &c., being determined.

#### MANGANESE SULPHATE.

With anthrapurpurin this mordant yields reddish-purple shades, much less blue than those produced by iron mordant, but bluer than the chromium shades. The best amount to use is 4—6 per cent.  $MnSO_4$ , but, unlike the iron mordant, an addition of cream of tartar or oxalic acid does not improve the shade. The presence of chalk in the dye-bath, which may be considered essential with iron mordant, has comparatively little effect, although 1—2 per cent. makes the shade slightly fuller. The single bath method may also be used, although the shades are not so full and bright as those dyed by the two-bath method; it is best to use 4—6 per cent.  $MnSO_4$  without addition.

*Alizarin S S powder*, probably anthrapurpurin sulphonic acid, gives exactly the same results as anthrapurpurin.

With manganese mordant, *Nitro-alizarin* gives brownish purple shades, very similar to those produced by madder with this mordant. The shades show a greater similarity to the chromium and copper than to the iron shades.

*Alizarin blue*, when dyed upon cloth mordanted with manganous sulphate, gives blue shades, which are lighter than those dyed with the same percentage of dyestuff upon chromium mordant. The colour is also made purer—i.e., less purple than the chromium shade.

*Alizarin black* gives very similar shades whatever mordant is employed, although the manganese colour has a reddish tone.

In the case of *Gallocyanin* (*Solid violet*) manganese gives very similar shades to aluminium—viz., reddish purples; while *Gallein* with this mordant produces bluish purples, almost identical with the chromium shade.

*Carulein* yields green with all mordants, which, however vary in tone. The manganese shade is greyish green.

The behaviour of *Resorcinol green* ("Dark green") is interesting. The iron compound of this colouring matter possesses a dark green colour, but with no other mordant is a green obtained. Manganese produces a greyish-brown shade. This is noteworthy, since it is a striking instance of the fact that two metals as closely related to each other as iron and manganese may produce totally different colours when combined with the same dyestuff.

*Anthracene brown* ("Anthrakoll") with manganese produces bluish brown shades, which are similar to those

obtained when bichromate of potash + tartaric acid (green mordant) is the mordant employed. Bichromate of potash alone gives much yellower shades.

With the natural colouring matters (dyewoods) the following results were obtained with manganese mordant:—

*Logwood* produces purplish browns, which are not nearly so blue as the iron shades. *Peachwood* gives brownish reds, less blue than the chromium shade, and much less blue than with iron. *Cumwood* gives dull reds, not unlike the aluminium shade, but duller.

The *Cochineal* manganese colour may be extensively employed if cochineal continues to decrease in price. It is a capital imitation of the shade produced by orchil, and, of course, very much faster. By suitable mixtures of iron, manganese, aluminium, and tin, the whole range of shades from bluish purple to scarlet can be obtained from this dyestuff alone, and if its price is reduced it would, no doubt, be extensively employed, not for scarlets alone, but also for the production of other shades not easily obtainable from the alizarin colours.

The yellow dyestuffs, *Old fustic*, *Quercitron bark*, *Flavin*, *Held*, and *Young fustic*, give very dull yellow shades with manganese mordant. *Persian berries* produce very green shades of yellow, greener than the weld-aluminium shade, and therefore the greenest possible shade obtainable from the natural dyestuffs. The shade, however, is not so bright as the weld colour above mentioned.

A general survey of the results of the experiments shows that there is a distinct similarity in the shades produced by the group of metals Mn, Fe, Ni, and Co. At the same time, several great differences in their behaviour are noticed. Oxalic acid has been spoken of as a very beneficial assistant with many mordants, but in no case is its good effect so marked as with iron mordant. It is interesting to note, therefore, that manganese, nickel, and cobalt are better without that addition. With iron mordant again, the presence of a lime salt in the dye-bath is often essential to the development of the colour, whereas it is found injurious with the same colouring matter when manganese, nickel and cobalt is the mordant.

With certain dyestuffs—e.g., Resorcinol green and the yellow woods—the three mordants above-mentioned yielded in the experiments an entirely different shade to iron.

Uranium, of course, belongs to a different group of metals to manganese, cobalt, and nickel, and it is not surprising, therefore, that it gives shades which differ entirely from any of those above described. This metal forms one of the chromium group, and we find that in many cases it gives shades more or less similar to those produced by chromium. With many other dyestuffs, however, the two metals produce very different shades.

With *Anthrapurpurin*, uranium sulphate yields very pleasing bluish grey shades. Mordant with 4 to 6 per cent.  $U(SO_4)_2$ , with a small addition of tartar or oxalic acid, and dye with 2 to 5 per cent. anthrapurpurin (20 per cent. paste). The greys may also be produced in a single bath, 4 to 6 per cent. of uranium sulphate or 6 to 8 per cent. of uranium oxalate being employed. The water used should be as pure as possible, since the presence of lime salts makes the shade redder, and thus greatly detracts from the excellence of the shades. This mordant has been used to a small extent for the production of greys by certain dyers on the Continent.

*Alizarin* is to be preferred to *anthrapurpurin* for the production of uranium greys, because it produces slightly bluer shades. *Flavopurpurin*, on the other hand, is not so satisfactory, since redder shades are obtained.

Uranium in conjunction with *Nitro-alizarin* produces purplish greys, and with *Alizarin black* purplish browns. Neither of these shades are particularly pleasing. With *Alizarin blue* very blue shades of grey are obtained. *Gallocyanin* with uranium gives similar shades to Alizarin blue and chromium.

With *gallein*, uranium yields a bright reddish violet shade, approaching that given by a red shade of Methyl violet, but not quite so bright.

*Carulein* produces yellower shades with uranium than with any other mordant.

Turning to the natural colouring matters, it is found that uranium and *logwood* produce a blue grey very similar to the alizarin-uranium shade, but somewhat duller, and as the cost of the dyestuff in dyeing these greys is very slight, it is certainly better to use the purer colouring matter, alizarin.

*Cochineal* gives similar shades to anthrapurpurin, and this is another point of similarity between this most interesting dyestuff and the alizarin colours.

With *peachwood* and *camwood* uranium gives similar shades to aluminium.

Rather curious results have been obtained with the natural yellow dyestuffs in conjunction with uranium mordant. In some cases the shades are similar to those produced by chromium, in others they are quite different.

With *Weld*, *Persian berries*, and *Flavin* the two metals give similar shades, *i.e.*, with *Weld* an old gold shade and with *Persian berries* and *Flavin* a bright reddish-brown. This reddish-brown shade is also obtained with uranium and *Old fustic*, while the chromium shade is old gold. The order is reversed with *Young fustic*, chromium producing a reddish-brown, uranium a dull olive.

From a general consideration of the results of the experiments with these new mordants, it appears that uranium gives shades which it is difficult to obtain as *fast* shades in any other manner; and although a somewhat expensive metal, it may well find a more extensive use as a mordant for the production of the grey shades before mentioned. Of the group manganese, nickel, and cobalt, the latter gives generally the best result; but since in all cases they give similar shades to some one or other of the usual mordants, only some special excellence in the properties of the colour they produce would warrant their application. It has already been found that cobalt with Alizarin orange produces an extremely fast colour.

The experiments showed there is often a great similarity in the shades produced by metals belonging to one group, *e.g.*, manganese, iron, nickel, and cobalt, and also chromium and uranium. The cases in which quite different shades are obtained are, however, almost as frequent, and it is impossible from present knowledge to formulate any theory upon the subject.

#### PATENTS.

*Improvements in the Bleaching of Fibre.* A. G. Salamon. London. Eng. Pat. 415, January 9, 1889. 6d.

THE scoured vegetable fibre is bleached by treating first with permanganate of soda, and then, after rinsing, with a solution of borax more or less saturated with sulphurous acid. About 11 lb. of permanganate of soda are, it is stated, required for a ton of the raw material.—E. B.

*Improvements in or Connected with the Dyeing and Printing of Animal and Vegetable Fibres.* B. Willeox, London. From "The Farbenfabriken vormals Fr. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 3934, March 6, 1889. 6d.

THE patentees have discovered that the so-called substantive dyes have the property of forming with the oxides of the earthy and heavy metals insoluble lakes, which in general are very fast. The results obtained vary according to the nature of the metallic salt and colouring matter employed, but in all cases a lake is produced, which is faster to light, boiling water and fulling than the original colour. In certain cases the metallic salt has the effect of changing the ordinary shade of the dye. Salts of iron, for example, render the shade duller; salts of nickel generally make it redder; others, such as those of zinc, have no effect on the shade. A striking result is obtained when salts of copper are caused to act upon the azo-dyes obtained from diamidodiphenol-ether, such as Benzoazurine 3 G and Azo-violet, the former rather reddish-blue being converted into a beautiful fast greenish-blue, the latter changing from a violet to a reddish-blue. Moreover the shades obtained on cotton by this treatment with the copper salt, no longer have the objectionable property of reddening under the

influence of heat. Such shades, however, resist the action of tin salts, so that discharge effects cannot be obtained by this means.

Zinc sulphate is found to be most suitable for use in treating dyed wool and silk, the dyed material being boiled for a few minutes with a quantity of the zinc salt corresponding to the depth of shade. In this way the colour on the animal fibre is rendered perfectly fast to fulling and milling, and is unaffected by boiling water.

The colour-lakes formed on cotton goods are not, as a rule, quite so fast as those obtained on wool and silk, but the resistance of the colour is increased as is shown by the fact that dyed cotton goods which have been treated with copper or nickel sulphate, can be soaped at 40° C., whereas the ordinary shades suffer even with soaping in the cold.

Salts of chromium, again, yield fast lakes with the various dyestuffs resulting from the action of the tetrazo compounds of benzidine, tolidine, diamido-carbazol, &c., upon salicylic acid and its homologues, and with the mixed dyestuffs made in part with the latter. On wool the lakes obtained are perfectly fast to fulling or milling and, on cotton, very fast to soaping. In printing, the chromium salt, for instance, the acetate, is added to the colour-mixture, which is printed and well steamed, or the printed goods can be passed through a solution of a chromium salt. In dyeing the goods may be previously mordanted with chromium, or treated with a chromium salt after dyeing.—E. B.

*A New or Improved System or Mode and Means applicable for Producing Marble Pattern and such like Papers.* W. B. Blaikie, T. S. Harper, and J. Campbell, Edinburgh. Eng. Pat. 4598, March 16, 1889. 6d.

MOLTEN metal, such as is employed in stereotype work, is cast in a layer of nearly-uniform thickness on a flat metallic or other surface. This surface may be either smooth or grained and, in some instances, preferably moistened with water, oil, wax, or other substances before casting the metal upon it. The metallic plates so cast are suitable for mounting with the level face upwards on blocks or may be bent round and secured to the circumference of a roller. Also, stereotype or electrotypes copies and reverses may be prepared, so as to give greater diversity in the designs and colourings of the patterns obtained.—E. B.

*Improvements in Open Soapers for Dunging and Soaping Fabrics.* J. Yates, Broadbottom, and G. Kay, Prestwich. Eng. Pat. 4991, March 22, 1889. 6d.

THE fabric to be treated passes into the first tank between a pair of india-rubber batters revolving on the surface and in a direction opposed to that of the fabric. Upon emerging from the tank the fabric passes between a similar pair of batters, but revolving in the same direction as that of the cloth. The cloth is then rinsed with water by means of a squirt-pipe, and passes over a steam-heated cylinder before entering the next tank of the series, which, like all the succeeding ones, is fitted similarly to the first.—E. B.

*Improvements in Yarn-dyeing Machines.* L. Weldon, Amsterdam, U.S.A. Eng. Pat. 18,971, November 26, 1889. 6d.

THE object of this invention is stated to be the provision of a machine, capacious enough to carry a large quantity of yarn and yet occupying a minimum space. The machine comprises a dye-vat, vertical rotary discs above the same, endless chains or bands passing round the discs and dipping into the dye-vat, and yarn-supporting bars carried on the bands or chains at the inner and outer sides of the latter. For exact details of the mechanism reference must be made to the drawings accompanying the specification.—E. B.

*Improvements in the Process of Treating and Scouring Wool and other Materials containing Greasy, Oily, or Fatty Matters, and in Machinery applicable thereto.* G. W. P. Kyre, London, and T. I. Hopkins, Trowbridge. Eng. Pat. 17,429, November 29, 1888. 11d.

THE material to be treated is placed in a cage inside a specially constructed centrifugal machine furnished with a water seal. Carbon disulphide or other suitable solvent is then run in, the enclosed air escaping through a vent. The machine is then rotated and the solvent allowed to run off into a tank. Water is then run in to cleanse the material and to wash out any remaining solvent. It runs into an intermediate tank, where any solvent carried with it settles to the bottom.

The rotation of the machine is continued until the material is dry. The drying may be assisted by means of air forced in by a fan.—E. J. B.

*Improvements in Dyeing and Scouring Machines.* J. P. Delahunt, West Pittston, U.S.A. Eng. Pat. 20,715, December 24, 1889. 8d.

THIS invention is an improvement upon a dyeing and scouring machine previously patented by the same inventor. The chief innovations are as follow:—The cylinder or cage is made with solid sides and heavy cross-bars at the periphery, and with perforated sheet metal or wire-work secured upon the inner faces of the cross-bars; instead of the straight pins formerly used to lift the raw material under treatment, there are now employed curved fingers fixed in rows and of different sizes. Two sets of such curved fingers may be fixed in each row, so that the machine may operate in either direction of rotation instead of in only one, as heretofore.

The mechanical arrangements in the original specification are described with the aid of drawings.—E. B.

## VII.—ACIDS, ALKALIS, AND SALTS.

*The Simultaneous Solubility of Potassium and Sodium Chlorides.* A. Etard. Compt. Rend. 109, 740—743.

THE accompanying diagram gives the solubility of potassium chloride and sodium chloride present in the same solution. The ordinates represent the percentage of salt in 100 parts of solution, and the abscissæ the temperature.

The conclusions to be drawn are as follow:—1. The sum of the salts dissolved is represented by a continuous straight line. (7.) From  $-20^{\circ}$  to  $+180^{\circ}$   $y \pm \frac{180}{20} = 27 + \cdot 0962 t$ . Some qualitative determinations lead the author to believe that the straight line is prolonged beyond  $180^{\circ}$ , but that at a certain point the quantity of water would practically be nothing; and he calculates that this "limit of solubility" would be  $738^{\circ}$ , which temperature is given by Carnelley as the fusing point of potassium chloride.

The different action of the mixed salts would not, however, be apparent from their solubilities.

The solubility of a mixture of the two salts is represented by a straight line. The slight inflections shown in the lines (1) and (4) are only passing, and may be taken as curves having points of inflection. These curves show, however, that change of solubility of either constituent may occur without the total solubility being apparent.

From the line giving the solubility of the mixture of potassium and sodium chlorides, the point of fusion would be  $738^{\circ}$ . At this point the calculated quantity of the two salts present would be 16.7 of NaCl and 83.3 of KCl. The sum of the metals and non-metal is then equal; that is to say, there are present the same number of molecules of chlorine and of the metals.—J. B. C.

*Isolation of a Tetrahydrate of Sulphuric Acid existing in Solution.* S. U. Pickering. Proc. Chem. Soc. 1889 (72), 128—130.

THE freezing points of mixtures of sulphuric acid and water form three distinct curves, representing the crystallisation

of water, of  $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$  and of sulphuric acid respectively: in each of them the highest point is in exact correspondence with the composition of the substance which crystallises out. No solutions containing between 75 and 40 per cent. of acid had yet been frozen, but it appeared to the author that if his former deductions from the irregularities in the curves representing the densities and other properties of solutions of the acid were correct, an independent curve representing the crystallisation of a new hydrate should occupy this interval, and that this new hydrate could only be either  $\text{H}_2\text{SO}_4 \cdot 5 \cdot 5 \text{H}_2\text{O}$  or  $\text{H}_2\text{SO}_4 \cdot 4 \text{H}_2\text{O}$ . Experiment proved that it is the latter. The two branches of the new curve obtained rise from about  $-80^{\circ}$ , and meet in a sharply marked angle at a point exactly corresponding to the composition of the tetrahydrate, the temperature at which this point is reached being  $-25^{\circ}$ . The tetrahydrate forms large, well defined, hard crystals.

Apart from the consideration that the isolation of this hydrate was the direct outcome of his having previously recognised its existence in the dissolved state, the author maintains that the crystallisation of a substance from a liquid necessitates the recognition of its existence in that liquid. The various possibilities are (1) that the solid constituents solidify separately in the proper proportions, and subsequently combine: this view is obviously untenable; (2) that the molecular aggregates constituting the solid are formed directly from the acid and water: this means that a hydrate has no fundamental molecule, and besides leaves the impossibility of explaining how these solid aggregates can hunt each other out, and congregate to form large crystals; (3) that fundamental molecules of the hydrate are formed in solution, but cannot remain there, and consequently separate out almost immediately: this is tantamount to saying that the hydrate is an insoluble substance, a proposition which could scarcely be maintained even if the substance were not crystalline; (4) that the molecules of the hydrate are formed in the liquid, and exist there till the temperature is lowered below its freezing point. This, in the author's opinion, is the only tenable hypothesis.

When a liquid freezes and melts at a definite temperature; when the temperature remains constant till the whole of the liquid is frozen; when any alteration in its composition lowers its freezing point: we have the most certain evidence yet adduced for regarding that liquid to be a definite though possibly somewhat dissociated compound. If we deny this argument as applied to the hydrate in question, we must deny it in all cases, and conclude that no liquid is a definite substance.

The author believes that the dihydrate may yet be obtained as a solid, since there is a reach of 7 per cent. in its vicinity where freezing points have not yet been attained. He has also isolated another hydrate which crystallises in small quantities with the monohydrate, but has not succeeded in determining its composition.

## PATENTS.

*Improvements in the Manufacture of Ammonia, and in Apparatus therefor.* A. Feldmann, Bremen, Germany. Eng. Pat. 3643, August 1, 1882. (Second Edition.) 8d.

Already described in this Journal, 1883, 380.—F. S.

*Improvements in the Treatment of Lime Refuse from Alkali Works, to render it suitable for the Manufacture of Cement, and in Apparatus employed therein.* James Hargreaves, T. Robinson, and John Hargreaves, Widnes. Eng. Pat. 94, January 3, 1889. 8d.

IN order to remove the sulphur and sulphur compounds present in carbonated alkali-waste, air, or some oxidising agent such as chlorine or bleaching-powder, &c., is blown through the mass made up into a cream with water. When the waste is only moist or semi-dry, air is blown through the heap when exposed to the atmosphere by perforated pipes passing in at the bottom. During the oxidation part of the sulphur is liberated as such, and this is dissolved by adding lime or lime sludge from the caustic soda manufacture. Another convenient solvent is the solution of calcium hydrosulphide obtained by steaming ordinary alkali

waste under pressure, but the best solvent of all is a solution of caustic soda or carbonate. On washing, all the sulphur is removed. Lime sludge is similarly treated by a preliminary oxidation, and the sulphur separated, dissolved in the alkali which is always present and then washed out. To filter the magma a special form of filter is used.

It consists of an outer perforated casing 1, lined with cloth placed between two layers of wire gauze, 2. There is an inner hollow shaft 3, enclosed in a perforated cloth-covered tube 4, the filtration thus proceeding both outwardly

and inwardly. The slurry enters at 5, and issues at 6; the slide for regulating the outlet is seen at 7, whilst 8 is the band for removing the filtered material. If required, the carbonated alkali waste, or lime sludge, or a mixture of the two, may be mixed with clay in the form of "slip," and oxidised, treated with a solvent to remove the sulphur, washed and filtered. The residue after drying is roasted and ground to form cement. The operations for removing sulphur and alkali are hastened by steaming, agitating and heating the mass.—S. G. R.

*Improvements in Apparatus for Volatilising Ammonium Chloride.* L. Mond, Northwich. Eng. Pat. 2160 February 6, 1889. 6d.

IN volatilising ammonium chloride, great difficulty has been found in procuring vessels able to withstand the corrosive

action of its vapours. Vessels of nickel or cobalt and their alloys, or iron vessels lined with these metals or their alloys, and of sufficiently large size being difficult to obtain, the patentee uses instead iron vessels lined with antimony, or an alloy of antimony. As antimony melts at a somewhat low temperature, the vessel is filled with melted zinc chloride to a level higher than that which the outside heating flame reaches. The apparatus employed is of the following description:—A represents the retort or chamber lined with antimony *a*, and filled up to the level *a'* with zinc chloride. The ammonium chloride is fed in through B, which is plugged by the rod *b*. C is the valve for washing out and emptying the vessel A. The ammonium chloride vapours are led away by the flue G. (See this Journal, 1887, 289; and 1888, 626.)—S. G. R.

*Improvements in the Manufacture of Cyanogen Compounds from Sulphocyanides.* T. Parker and A. E. Robinson, Wolverhampton. Eng. Pat. 2383, February 11, 1889. 4d.

THE solution containing the sulphocyanide is precipitated by sulphate of copper and a suitable reducing agent, such as sulphate of iron or sulphurous acid. The precipitated cuprous sulphocyanide is treated in the moist state with carbonic anhydride or with sulphuretted hydrogen under pressure so as to obtain carbonate or sulphide of copper and sulphocyanic acid. The sulphocyanic acid thus brought into solution is separated from the insoluble copper salts by filtration. The filtrate is subjected to electrolysis for the separation of the hydrocyanic acid which is condensed in water, to form the hydrocyanic acid of commerce, or in a solution of an alkali or of an alkaline earth to form a cyanide.—F. S.

*Improvements in Volatilising Ammonium Chloride, and in obtaining Ammonia, Chlorine, and Hydrochloric Acid therefrom, also in obtaining Chlorine from Hydrochloric Acid.* L. Mond, Northwich. Eng. Pat. 2575, February 13, 1889. 8d.

THE vessel A is made of iron lined with antimony, it having been found that this metal resists the corrosive action of the ammonium chloride vapour better than any others. (For further details of the vessel A see adjoining Figure.) The vessel H is made of bricks or tiles of fireclay set in a cement which may be made of barium sulphate and sodium silicate, and is closed both at top and bottom. Outside the tiles is fitted an iron jacket. There are various inlet and outlet tubes, two of which are shown at G and K. Through the opening I are fed in the "pills" consisting of a mixture of 100 parts of magnesia, 75 parts of china clay, and 6 parts of lime made into a stiff paste with potassium chloride solution, and moulded into pellets of about half

an inch in diameter. The magnesia is preferably precipitated from sea-water, carefully washed, and ignited. The working of the apparatus, so far as concerns the vessel H, depends on the gases passed between these pellets and

upon the temperature employed. The vessel H is heated to  $350^{\circ}$ — $400^{\circ}$  C., and the vaporised ammonium chloride introduced through the flue G from the vessel A, the ammonia produced being led away to an absorption

apparatus. The supply of ammonium chloride is then cut off and the temperature raised by passing in heated inert gases, free from oxygen and aqueous vapour, from a limekiln or other source. A little more ammonia is at first evolved and is removed. When the temperature has risen to about  $500^{\circ}$  C. hydrochloric acid is given off and is taken away in its turn to the condensing plant. Carefully dried air at a temperature of from  $800^{\circ}$ — $1,000^{\circ}$  C. is now passed in and chlorine produced by the decomposition of the magnesium chloride. When the percentage of chlorine in the gases evolved falls below seven, the air containing this small amount of chlorine is again heated up to  $1,000^{\circ}$  C. and passed into another of the vessels ready for the evolution of chlorine. Cool air is then allowed to traverse the vessel H to reduce the temperature to  $400^{\circ}$  C. while the air, thus partially heated, passes through a Cowper's stove and thence to another chlorine-evolving apparatus. More ammonium chloride vapour is passed into H and the operations begin afresh. By using gases containing hydrochloric acid in the above apparatus instead of vaporised ammonium chloride, chlorine can be advantageously obtained. (See this Journal, 1887, 140, 216, 217, and 289; also 1888, 626.)

—S. G. R.

*Improvements in the Method or Process of Treating or Utilising the Spent or Residual Liquid formed in the Process of Cleaning Iron or Steel with Hydrochloric Acid.* T. B. Saunders, Cleckheaton. Eng. Pat. 3757, March 4, 1889. 6d.

SCRAP-IRON is added to the residual liquors to neutralise all the free acid, and the solution is evaporated to dryness. The chloride of iron is then treated with sulphuric acid, the hydrochloric acid evolved being condensed by suitable means. The sulphate of iron remaining may be either crystallised

or converted by roasting into the oxide. The process is carried out as follows:—

The spent liquor is run into the tank *a* containing scrap-iron and thence pumped to the tank *b*. This is in communication by *C* with the boiling-down pan *e*. After concentration, sulphuric acid is run in by the pipe *m* from the tank *o*. The hydrochloric acid evolved passes away through the flue *r* of the roaster *l* to the condenser *t*. The pasty mass of sulphate is then pushed over into the chamber *k*, and there dried by the waste heat from the furnace *F* which traverses the flues *u* and *v*.—S. G. R.

(For illustration, see next page.)

*Improvements in the Manufacture of Ammonium Nitrate.* E. Carez, Brussels, Belgium. Eng. Pat. 4316, March 12, 1889. 4d.

BARUM sulphate by roasting with charcoal and resin oil is converted into the sulphide, which boiled with water and sulphur forms a solution of polysulphide. The solution, when mixed with sodium nitrate and concentrated, yields barium nitrate, which by double decomposition with ammonium sulphate forms ammonium nitrate, while barium sulphate is precipitated.—S. G. R.

*Process of Manufacture of Ammoniacal Calcic Phosphate.* G. A. H. Gabet, Paris, France. Eng. Pat. 5340, March 28, 1889. 6d.

AN acid solution of calcium phosphate is treated with either gaseous ammonia led directly into the solution, or else with ammoniacal liquor. The solution gradually becomes pasty, and the mass can be easily dried. It is claimed that simul-

taneously with the formation of a new industrial product a method for fixing ammonia, not previously in use, has been devised. As a manure it is stated to be richer in nitrogen and phosphoric acid than any other known.—S. G. R.

*An Improved Process of Producing Ammonium Nitrate.*

A. W. and J. A. Wahlenberg, Stockholm, Sweden. Eng. Pat. 12,451, August 6, 1889. 4d.

A SUITABLE nitrate is decomposed by a salt of ammonia such as ammonium sulphate, ammonium carbonate, or ammonium chloride. The ammonium nitrate formed is separated from the other salts and impurities by means of alcohol.—F. S.

*Improvements in the Manufacture of Acetic Acid, Soluble*

*Acetates, and Calcium Sulphite.* J. E. Johnson-Johnson, Stratford. Eng. Pat. 17,348, November 1, 1889. 4d.

ACETIC acid is prepared from calcium acetate by heating equal weights of calcium acetate and water to about 100° F., and passing sulphur dioxide gas through the semi-liquid mass, which is kept in motion by a stirrer, until fully saturated with the gas. The sulphite of calcium is separated by decantation and filtration from the acetic acid, which may be purified by any suitable and well known process, but preferably by that described in Eng. Pat. 13,336 of 1887 (this Journal, 1888, 628). Acetate of soda is prepared by treating calcium acetate in a semi-fluid mass, and heated to 100° F. with sulphite of soda, or by decomposing the calcium acetate, before or after the addition of sodium hydrate and carbonate, by sulphur dioxide.

Weak and impure acetic acid (pyroligneous acid) can be treated by the above process.—F. S.

*Improvements in the Manufacture of Acetic Acid and*

*Soluble Acetates.* J. E. Johnson-Johnson, Stratford. Eng. Pat. 20,135, December 14, 1889. 4d.

WHEN acetic acid is to be prepared the salt employed, preferably "lime salt" or crude calcium acetate, is treated with hydrochloric acid. On distillation acetic acid comes over, calcium chloride remaining behind in the still. If a soluble acetate, such as the sodium salt, be required, then calcium acetate in a semi-liquid state may be mixed with sodium chloride and the whole thoroughly stirred, sodium

acetate and calcium chloride being the products of the reaction. Similarly the sodium salt can be obtained by treating a mixture of calcium acetate and sodium carbonate or caustic soda with hydrochloric acid. Crude or weak acetic acid such as pyroligneous acid can be neutralised with sodium or calcium salts, and then treated by one of the above methods, producing a pure acid.—S. G. R.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

*On the Devitrification of the Ordinary Glass of Commerce.*

Appert and Henrivaux. *Compt. Rend.* **109**, 827—829.

By heating glass at a temperature near to that at which it begins to solidify, crystals of varying composition are obtained according to the composition of the glass. The smallness of the crystals and their intimate admixture with the residual glass only permits of their examination microscopically. A glass rich in soda and lime gives crystals of wollastonite distinguished by their occurrence in the monoclinic system in flattened prisms produced in a direction parallel to the ortho-diagonal. Their optical properties also correspond with those of wollastonite. When the bases present, as in common bottle glass, are magnesia and protoxide of iron, then pyroxene is the predominant form, the crystals exactly resembling diopside, with the same crystalline form, cleavages, &c. They can be distinguished from wollastonite by their faint green colour, their refraction and their angle of optical extinction. If the glass contains alumina as well as these bases then feldspars of different varieties are the principal results.—S. G. R.

*On the Composition of the Minerals ("Roches") made use of in China for the Manufacture of Porcelain.* G. Vogt. *Compt. Rend.* **110**, 43—45.

ANALYSES made in former years by Ebelmen and Salvétat led them to suppose that the difference in composition between the materials used in China, termed "yeou-ko"

and "petun-tsé," and the pegmatite of Limousin, was but small. If these substances be fused with sodium carbonate, and treated with hydrofluoric acid, then the percentage compositions of them all closely agree with one another. Treatment with hot concentrated sulphuric acid, however, brings great differences to light. Whilst pegmatite only yields up about 3 per cent. of soluble matter to the acid, "yeon-ko" dissolves to the extent of 34.15 per cent., whilst of the remaining 66.36 per cent., as determined by actual experiment, 52.95 per cent. is quartz and 13.41 per cent. soda felspar. The soluble portion corresponds to a formula  $6 \text{SiO}_2 \cdot 3 \text{Al}_2\text{O}_3 \cdot \text{K}_2\text{O} \cdot 6 \text{H}_2\text{O}$ , which is the formula of muscovite. Hence "yeon-ko" has the following composition:—

Quartz .....	52.9
Muscovite or white mica .....	31.3
Soda felspar .....	13.4
Calcium carbonate .....	2.0
Hydrated silica .....	1.0
	<hr/> 100.6

whilst the composition of pegmatite is—

Quartz .....	23.87
Felspar .....	72.83
Matter soluble in sulphuric acid .....	3.30
	<hr/> 100.00

The presence of muscovite or white mica in many of the Chinese products is shown by the following analyses:—

	Petun from			
	Cheo-Ki.	Yu-Kan.	Ki-Men.	Sang-Pao-Pong.
Muscovite, per 100 parts.	40.6	37.3	31.1	18.6

Muscovite was also detected by the microscopical examination. Although the percentage compositions of pegmatite and these Chinese minerals are much the same, yet they are in reality formed of very different substances, and the presence of such large quantities, about 20 per cent., of mica will probably exert a very appreciable influence on the qualities of the porcelain made from such sources.—S. G. R.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

### PATENTS.

*Improvements in the Treatment of Lime Refuse from Alkali Works, to render it suitable for the Manufacture of Cement, and in Apparatus Employed therein.* Jas. Hargreaves, T. Robinson, and John Hargreaves, Widnes. Eng. Pat. 94, January 3, 1889. 8d.

See under VII., page 290.

*Improvements in the Manufacture and Utilisation of Cement and Plaster, and in the Machinery and Appliances therefor.* R. Stone, London. Eng. Pat. 116, January 3, 1889. 8d.

The patentee adds to a mixture, composed of about 25 per cent. of river mud with about 75 per cent. of chalk, about 10 per cent. of "sawdust or other suitable fibrous material," saturated with petroleum, petroleum spirit, sulphuric acid

or oil, in the proportion of about 6 galls. of the liquid to 1 ton of the absorbent. The mixture is then burnt, and it is claimed that cement of high quality is produced, and that "all the sulphur is removed." Another material patented is composed approximately of 25 per cent. of flints, 25 per cent. of river mud, and 50 per cent. of chalk, burnt and ground together; it may be moulded by plain or grooved rolls and moulds. Plant for the manufacture of cement is also claimed; it includes several grinding arrangements, consisting of rolls, cylindrical or barrel shaped, run in contact with others of corresponding shape, at different speeds, so as to enhance the grinding action, a cylindrical vertical furnace, with or without a blast, and a horizontal furnace, through which pass endless bands for effecting the loading, burning and withdrawal of the cement continuously.

—B. B.

*Improvements in the Manufacture of Artificial Stone.* A. C. Ponton, Parkstone, B. L. Mosely and C. Chambers, Hastings. Eng. Pat. 2780, February 16, 1889. 4d.

SAND, gravel, pebbles, or similar siliceous material is mixed with a solution of an alkaline silicate and (optionally) with powdered burnt flint or sand, separately or together, moulded by pressure, and fired.—B. B.

*Improvements in or relating to the Manufacture of Artificial Siliceous Stone.* A. C. Ponton, Parkstone, B. L. Mosely and C. Chambers, Hastings. Eng. Pat. 2781, February 16, 1889. 4d.

Siliceous materials, such as sand, gravel and flints, are heated until the silica they contain is converted into the amorphous variety termed by the patentees "Tridymite" (this Journal, 1890, 190), the completion of the change being defined by the specific gravity of the material ceasing to alter. The product is cemented by a solution of soluble glass, moulded and fired.—B. B.

*Improvements in Arrangements for Drying Slurry by the Waste Heat from Cement Kilns.* G. Batchelor, Frindsbury. Eng. Pat. 4333, March 12, 1889. 8d.

At the back of a cement-burning kiln are built two arched chambers, one above the other, of such size that the total floor space they afford suffices for the reception of a full charge of slurry for the kiln. The products of combustion from the kiln are led into the slurry-drying chambers, circulated through them, and discharged into a chimney shaft at the end remote from the kiln. Both floors of the chambers are inclined slightly towards the kiln (about 1 in 300) so as to have the greatest thickness of slurry at the hottest part, and in them openings, with a brick edging to confine the slurry, are provided, to allow the flow of hot gases from one to the other. The slurry to be dried is contained in tanks formed in the depressions between the arches that compose the drying chambers, and is led thence through shafts or passages on to the floors of both upper and lower drying chambers. The arrangement is applicable for a group of kilns built side by side as well as those standing by themselves.—B. B.

*Improvements in the Manufacture of Cement.* J. W. H. James, London. Eng. Pat. 5157, March 26, 1889. 8d.

THE patentee asserts that in the modern method of making cement by the use of revolving furnaces, sufficient time is not given for the complete reaction of the materials on each other, and accordingly provides "maturing chambers," into which the clinker is passed as it leaves the furnace, and in which it is maintained at a high temperature for the requisite period. In the arrangement illustrated in the specification the maturing chamber is set vertically below the mouth of the revolver, from which the clinker either falls directly into the chamber down a shoot, with a door at the point of entrance to regulate its admission, or is carried thither by

an endless band, revolving table, or similar device. The maturing chamber tapers towards the bottom, and the finished clinker is removed by a worm and transferred to the mill. The chambers are worked in sets of four, one being charged while another is being discharged, and the remaining two in action and full of clinker.—B. B.

*Improvements in the Manufacture of Artificial Stone or of Articles formed of the same.* W. P. Thompson, Liverpool. From C. Kohn, Teschen, Austria. Eng. Pat. 17,640, November 6, 1889. 6d.

"EQUIVALENT parts" of powdered quartz and calcined magnesite, or "a double portion of quartz and one portion of calcined magnesite" are mixed with diluted soluble potash glass to form a stiff paste, moulded, and "freed from the superfluous amount of water at a temperature of about 15° C." The moulded blocks are subjected to a vacuum, and then to carbonic acid under a pressure of 1–10 atmospheres, the result being "that the hydrate of oxide of magnesium is completely converted into carbonate of magnesium, which in its turn combines with the quartz to form carbo-silicate of magnesium."

The product is said to be hard, unaffected by weather, and of high compression strength. The method of carbonation described may be applied to blocks of artificial stone already made by the known process of treating magnesite with magnesium chloride. An artificial stone not liable to fracture on being strongly heated may be made by inserting a network or perforated sheets of asbestos or similar material during the process of manufacture.—B. B.

*Improved Manufacture of Artificial Granite.* P. de Kristoffovitch, Paris, France. Eng. Pat. 18,911, November 25, 1889. 6d.

THE raw materials used are two kinds of clay possessed of the following characteristics:—

(1.) A less fusible clay containing less than 7.75 per cent. of ferric oxide, and not less than 42 per cent. of silica, and losing on ignition not more than 10 per cent.; its "coefficient of infusibility" (Bischoff) should be not less than 3.

(2.) A more fusible clay with as much as 14 per cent. of ferric oxide, silica varying from 42 to 73 per cent., and losing on ignition not more than 8 per cent.; its "coefficient of infusibility" may vary from 0.5 to 1.

One to two parts of (1), ground and sifted, are mixed with two to one parts of (2), previously baked, ground and sifted, and 6 to 20 per cent. of water is added. The mass is moulded under a pressure of from 200–1,000 kilos. per sq. cm., or where the use of pressure is impracticable from the shape of the articles to be made, moulded after adding more water to form a paste. The objects thus shaped are dried and ignited at a temperature above the melting point of (2), and about 150° C. below that of (1), becoming agglomerated and capable of receiving a polish. The cooling should be slow to avoid cracking. Granite may be imitated by using the more fusible clay in granules instead of powder. The product may be used as a building material generally, and is to be called "pyrogranite."—B. B.

## X.—METALLURGY.

*The Use of Bichloride of Mercury in the Saving of Fine Gold.* B. F. Wilson, jun. Eng. and Min. J. 1890, 60.

A SOLUTION of bichloride of mercury is made by the action of an electric current on a solution of common salt, metallic mercury at the bottom of the trough containing the salt solution being one pole and suspended carbon slabs the other. A trace of bichloride of mercury is formed in the

solution while the lower chloride is precipitated. The calomel is taken from the bottom of the generating boxes and treated with nitro-hydrochloric acid. The solution is concentrated and siphoned off, and its strength tested by its ability to coat copper wire. It is then passed from the tank to the grinder pan, where it permeates the ground-up particles of ore, and amalgamates with the very fine particles of gold which might otherwise escape and not be touched. The mercury in the pans serves the double purpose of amalgamating with the coarser gold and collecting the amalgamated particles which the bichloride attacks. If the solution be too strong it comes over with the tailings, thereby causing a loss. "The problem remains: how are we to use a strong solution and not lose any of it in the tailing pan? When that problem is solved the use of bichloride of mercury in gold amalgamation will be an established fact." "As it is, it is a great helper."—A. J. S.

*Comments on the Chemical Reactions in the Blast Furnace.* A. D. Elbers. Eng. and Min. J. 49, 227.

THE author discusses the nature of the chemical changes taking place in the blast furnace, and draws the following conclusions:—

"1st. The reduction and complete saturation with carbon of  $\text{Fe}_2\text{O}_3$  requires theoretically one pound of CO for each pound of Fe, and that of  $\text{Fe}_3\text{O}_4$ : one-twelfth less.

"2nd. The proportion of the quantity of CO that is required for actual carburisation increases much more rapidly with the degree of saturation than the theoretical proportion.

"3rd. The more completely the reducing ore becomes carburised the less heat is required for its fusion; in other words, 75 pounds of Fe and 30.36 pounds of  $\text{FeC}$  (= 105.36 pounds of  $\text{Fe}_3\text{C}$ ) require less heat for fusion than 100 pounds of Fe,  $\text{Fe}_3\text{C}$ ,  $\text{Fe}_3\text{C}$ , &c."—O. H.

*Mining Industry in Siam.* Board of Trade Journal, 8, 1890, 340–342.

TIN is found principally in the Malay Peninsula. Great Britain and Siam now divide this invaluable peninsula between them, but whereas in the British portion of the country companies are being rapidly formed to work mines, in the Siamese districts, or to speak properly, in the native Malay States, over which Siam claims suzerainty, the numerous mines to all practical purposes still lie awaiting the enterprising hand to come and throw their abundant treasures open to the world. The most productive mines are at a place called Lampang, which is situated at the foot of a hill from 3,000 to 4,000 feet high. Jala, which is a considerable way in the interior, is completely encircled by hills, and the surrounding country is rough and hilly. The tin ore is found here in small grains, and lies in patches in the alluvium of the valleys and on the hillsides close to porphyritic granite rocks. Tin quarries, more than a mile long in many cases, extend along the valleys and up the hillsides, while copper, when found, has been described as existing in almost solid isolated blocks.

In the island of Junk Ceylon, on the west coast of the peninsula, it is reliably stated that under such primitive conditions as described above an annual output of three million dollars' worth of tin is produced. This is much less than what it used to be before the administration of the island was taken from the semi-independent Rajah and handed over to a commissioner at Bangkok, and is indubitably only a tithe of what might be produced under properly-organised management.

Lakon and the island of Junk Ceylon are, however, not the only places where tin and copper are found, for, as already remarked, Chinese are engaged in tin-mining all over the peninsula, and there is no reason to doubt that the range of hills separating Siam from British Burmah has been upheaved under the same geological conditions as the continuation of it which passes right down the Malay Peninsula, and now shown to be so rich in metals. Mouhot,

the celebrated naturalist and traveller in Siam, in 1862 describes the district of Petchabourne to the north-east of Bangkok, near the great bend of the Mekong River, as the richest mineral district in Siam. Besides argentiferous copper and tin, he found traces of magnetic iron and antimony. Of these only iron was worked to any extent, and knives and tools of native manufacture were supplied to all the north-eastern part of Siam.

Gold is found in different places in Siam, and since time immemorial has been produced in the imperfect native fashion. Bangtaphan, which lies on the east side of the Malay Peninsula, about 10° N. lat., has for centuries been the most celebrated gold district in the kingdom. That gold exists there in large quantities is undoubted, but the British company which now works these mines has laboured under several initial disadvantages, of which the most damaging is the unhealthy nature of the surrounding jungle.

As regards the presence of gold and precious stones, Korat, which is situate to the north-east of Bangkok, may be described as having the same reputation as Kabin, and gold, to a more limited extent, has been found in the low hills which separate Siam from Cambodia.

There are no silver mines worthy of the name anywhere in Siam; but that the metal exists in many districts is fully established, and only proper working would furnish reliable estimates as to the wealth of the country in silver.

Coal has been discovered cropping up through the surface on the western coast of the Malay Peninsula, and ironstone has been found in the same place. As previously mentioned, iron ore is produced in the northern part of the kingdom.

#### *The Manufacture of Steel by the Direct Process.*

An ironworks in Pennsylvania is said to have been making steel by the direct process for a year past. Rhode Island graphite was formerly used to absorb the impurities of the iron ore. The graphite was a success, but the freight on it amounted to a considerable figure, and the company looked around for something with which to replace it. They experimented with coke, and soon found that it would answer all purposes when treated with milk of lime. When coke was broken into small pieces and soaked in thin milk of lime all the impurities of the ore were fused, the oxygen of the iron joined with the carbon of the coke, passing off as carbonic acid gas, leaving the impurities in such a shape that they could be eliminated. By this means the blast furnaces are done away with, and a great deal of expense avoided. The coke has now been in use for over a year, and as a result, the carbon works are turning out some of the finest bridge-plates made in the United States, and steel is being produced which is very low in phosphorus.

#### *A New Alloy.*

A new alloy has been discovered by Herr Rieth, Bockenheim, Germany, which is said to practically resist the attack of most acid and alkaline solutions. Its composition is as follows:—Copper, 15 parts; tin, 2·34 parts; lead, 1·82 parts; antimony, 1 part. This alloy is, therefore, a bronze, with the addition of lead and antimony. The inventor claims that it can be very advantageously used in the laboratory to replace vessels or fittings of ebonite, vulcanite, or porcelain.

#### PATENTS.

*Improvements in the Method or Process of Treating or Utilising the Spent or Residual Liquid formed in the Process of Cleaning Iron or Steel with Hydrochloric Acid.* T. B. Saunders, Cleckheaton. Eng. Pat. 3757, March 4, 1889. 6d.

See under VII., page 292.

*Improvements in the Manufacture of Copper.* P. C. Gilchrist. Eng. Pat. 4882, March 20, 1889. 6d.

The improvements relate to the separation of copper from impurities, more especially arsenic, antimony and tin. In the roasting of white or pimple metal for the production of blister copper, in the treatment of metallic bottoms for the removal of arsenic and conversion into blister or into refined copper, and also in the toughening and refining of blister copper, reverberatory furnaces are used lined with shrunk dolomite, magnesite, chrome iron ore, or other basic or neutral lining, by which means it is possible to maintain during the operation of refining a basic slag instead of the acid slag as hitherto. A purer product is thus obtained, together with a larger yield and increased output. It has been found that a suitable amount of lime to add when charging white metal containing 75 per cent. of copper, is from two to three cwt. per seven tons of white metal charged. The metal should be melted down slowly under air. Much less slag will be formed than is usual in sand-lined furnaces. A good heat should be kept on the furnace throughout the charge. It is often advantageous to add a few shovels full of lime to the slag shortly before tapping the charge. Care must be taken not to form too thick a slag or the operation will be retarded. It is often convenient to charge in also some copper oxides or slags, and to subject the surface of the bath to the action of an air blast, the oxidising action of which materially assists the diminution of the arsenic. The object of the smelter should be to obtain as little slag as possible, and with a low percentage of copper in it. Skimmings of slag should be made three or four times as desirable. When the sample begins to show a blister fracture a few shovels of lime are to be added once or twice until the bath is ready for tapping. The slags obtained when working as described will not average more than 30 per cent. of copper, whereas when working with the ordinary sand bottoms the slag usually averages 55 per cent. of copper, besides weighing considerably more per ton of blister produced. It was found when treating 400 tons of metallic bottoms in a basic-lined furnace that there was obtained 323 tons of blister and 107 tons of slag, averaging 25 per cent. of copper, and that when treating an equal weight of metallic bottoms in a sand-lined furnace there was obtained 191 tons of blister only, and 221 tons of slag, averaging 55 per cent. of copper. A slag in which there is no more silica than 20 per cent. should be worked with, as with more siliceous slags the elimination of the impurities takes place more slowly.—A. J. S.

*Improvements in and relating to a Process of and Apparatus for Producing Steel direct from the Ore.* W. F. M. McCarty, W. H. Ashton, and H. D. Walbridge, Washington, U.S.A. Eng. Pat. 9289, June 4, 1889. 8d.

The ore and flux are passed through a blast furnace by falling from one to another of a series of shelves built out from the walls, and during the downward passage are subjected to a current of hydrogen gas, which reduces the ore; after which the metal is melted by introducing hydrogen and carbonaceous matter with air or gas, which converts it into steel. The specification contains drawings of the furnace and eight claims.—A. W.

*Improvements in or relating to Amalgamators for Extracting Precious Metals from the Various Impurities combined with them in Ores and the like.* W. P. Thompson, Liverpool. From J. B. Brewster, New York, U.S.A. Eng. Pat. 16,396, October 17, 1889. 8d.

This apparatus, which has for its object the "working of ores of a friable or semi-fluid, sticky nature," consists of a deep vertical "pocket," an inclined screen, and a stepped incline terminating in another smaller pocket. Mercury is placed in these two pockets, and the pulp is fed into the larger one and lifted out again on to the screen by means of a row of endless revolving chains. The larger particles are caught by the screen and roll down to its side, while

the finer pulp is carried through the screen over the stepped incline to the smaller pocket, where the amalgamation is completed.—A. W.

*An Improvement in the Art of Treating Copper and its Alloys.* G. G. Mullins, Los Angeles, California. Eng. Pat. 16,649, October 22, 1889. 4d.

"THE object of this invention is to render more fusible, refine and improve copper and other metals in admixture to form alloys; to remove the dross, scoria, or slag; to prevent porosity; to harden and toughen the metal, and greatly increase its tensile and resilient strength." On the bottom of the crucible, or on the bed of a reverberatory furnace, from 1 to 10 per cent. of a flux consisting of 4 parts of silica, 3 parts of fluorspar, 2 parts of carbonate of potassium, and 1 part of tungstate of sodium is placed, according to character and weight of metal charged. When all is molten the bath is thoroughly stirred, allowed to remain quiet for a few moments, the dross skimmed off, and the process proceeded with as usual. Or from 1 to 10 per cent. of the flux, carried in paper bags, is placed in the already molten metal, thoroughly stirred, and the process carried on as usual.—A. J. S.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### PATENTS.

*Improvements in Processes for the Extraction and Electro Deposition of Aluminium and Aluminium Alloys.* P. Marino, Paris, France. Eng. Pat. 14,445, October 8, 1888. 6d.

SALTS of ammonium and salts of aluminium are electrically decomposed, oxygen and acid appearing at the "positive pole" and hydrogen and the aluminium base at the "negative pole." Five baths are described in which different salts of aluminium are used and in which the ammonium is obtained from the chlorhydrate of ammonia. Several other baths are described in which sodium, potassium, &c. are employed. The salt of aluminium preferably used is hauxite. By placing at the positive pole of one of the above baths a metal such as gold, tin, nickel, &c., any desired alloy can be obtained by the simultaneous deposit of aluminium and the particular metal made use of. Before the articles to be coated are put in the bath, they are thoroughly cleaned and treated with nitrate of mercury. The method is applied to the coating of glass with aluminium.

—B. T.

*Improvements in the Manufacture of Aluminium and its Alloys.* W. Diehl, Berlin, Germany. Eng. Pat. 813, January 16, 1889. 8d.

FOR the separation of aluminium and its alloys by electrolysis, a bath is prepared of the fluorides of alkali metals, or the compound fluorides of the alkali metals and anhydrous alum, a sulphate of an alkali and chloride of sodium. The substances are taken in the proportions given in the following equation, viz. :—

or

and melted together in a crucible. When melted, they are allowed to cool down, and are then ground and thoroughly washed in water to get rid of all traces of the sulphate. The fluoride thus formed will contain, for 1 mol. of aluminium fluoride, 1 mol. of alkaline fluoride,  $\text{Al}_2\text{F}_6, 1 \text{ NaF}$ . This

compound fluoride is now melted with an alkaline chloride, e.g., chloride of sodium, in proportion about the chemical equivalent of the aluminium fluoride, with as much fluorspar as the molten mass will take up, and while in a molten state the mass is submitted to a current of electricity, aluminium being collected on the negative pole, and chlorine liberated at the positive pole. In addition, a certain amount of alkali fluoride will be formed in the molten mass, as indicated in the following equation—

This sodium fluoride, if melted with anhydrous alum, will form the double fluoride,  $\text{Al}_2\text{F}_6, 1 \text{ NaF}$ , and will be in a condition to be subjected to electrolysis, as before explained, after the mixture has been thoroughly washed and the alkaline chloride added thereto. In place of the anhydrous alum an aqueous solution of nitrate of aluminium,  $\text{Al}_2(\text{NO}_3)_6$ , may be used for the purpose of producing the compound fluoride of aluminium to be treated. The compound fluorides of aluminium and alkali may also be taken and melted with fluoride of barium, without any chloride. Thus—

The various compounds obtained by the above means are subjected to the action of the electric current in a crucible heated in a furnace. When employing a retort carbon as cathode, the desired quality of the aluminium is not obtained, nor the desired output, as compared with the electric power expended; it is therefore preferable to produce, first, an alloy by an electrolytic process, from which the aluminium can be afterwards separated by means of commonly known processes. If either of the metals—iron, copper, cobalt, or nickel—he employed as the cathode, the current must be so regulated that an alloy rich in aluminium shall be obtained from the cathode. This easily fusible alloy is separated by careful fusion, into a crystalline alloy difficult of fusion and containing little aluminium, and a pure or nearly pure aluminium, comparatively easily fusible. This separation proceeds more effectually when it takes place in combination with certain salts which will not undergo chemical change, but only facilitate the separation: alkaline chlorides in union with alkaline nitrates; earthy alkali chlorides and alkali nitrates, &c.—A. J. S.

*Improvements in Secondary Batteries.* F. King, London. Eng. Pat. 1420, January 25, 1889. 8d.

EACH plate is provided with two lugs diagonally opposite each other, all the bottom lugs of one set, say the negative set, being burned into a strip of connecting metal which serves as a support, and all the bottom lugs of the other set being burned into a similar connecting strip which also serves as a support, but these two connecting strips are kept on opposite sides of the containing vessel. Notched distance-pieces of insulating material are inserted at each of the four corners and held in position by suitable lugs on the framework.—B. T.

*A Process for the Production of Pure Double Chlorides of Aluminium.* H. Y. Castner, London. Eng. Pat. 1989, February 4, 1889. 6d.

THE double chloride of aluminium or sodium prepared in the ordinary way contains small quantities of the chlorides of iron, which latter, when the material is used for making aluminium, become reduced, an impure aluminium being the result. To purify the double chloride it is melted and subjected to the action of the necessary quantity of aluminium, sodium, or other convenient metal, to decompose the chlorides of iron. The metallic iron which is produced sinks through the molten mass, while the colourless purified double chloride is drawn off or distilled in any convenient manner.

When an alkali metal is used it reduces some of the iron together with some aluminium, the latter in turn reacting with the remainder of the impurity.—A. W.

*Improvements in the Manufacture of Cyanogen Compounds from Sulphocyanides.* T. Parker and A. E. Robinson, Wolverhampton. Eng. Pat. 2383, February 11, 1889. 4d.

See under VII., page 291.

*Improvements in or Connected with Processes of Manufacturing Iron wherein the Iron is Subjected to an Electric Treatment.* A. G. Greenway, West Derby, and B. F. Babcock and B. Radcliffe, Liverpool. Eng. Pat. 3502, February 27, 1889. 8d.

THIS invention relates to improved methods of subjecting molten iron to electric currents in order to purify it and increase its strength. For this purpose electrodes of carbon are placed in the runners or gutters of the furnace or in a depression or chamber in the path of the same. Or, if desired, the electrodes may be placed in a receiver such as those used to convey metal to Bessemer converters. A current of air may be blown through the molten metal to aid in the process of purification.—E. T.

*An Improved Process for the Production of Fixed or Detachable Deposits of Homogeneous Iron in any Form, Size, or Thickness, from Iron Ores or Steel, or Iron in any Form.* A. E. Barthel, London. Eng. Pat. 5078, March 23, 1889. 6d.

THE object is to produce iron of greatly improved quality by electro-deposition. A bath is made up by precipitating ferrous oxide from ferrous sulphate by sodium carbonate and dissolving in strong sulphuric acid, using definite proportions of all ingredients. Anodes may be of cast or wrought iron, steel, or iron ore. A bath made by adding sodium sulphate to ferrous sulphate may also be used, but is not so good as that first described. Temperature should be from 14° to 40° R.—E. T.

*Improvements in Electric Batteries.* H. H. Lake, London. From Lacombe and Co., Paris, France. Eng. Pat. 5563, April 1, 1889. 8d.

A TUBE of carbon, forming one electrode, is placed in the position of the porous cell of an ordinary Leclanché cell. Inside this is a small porous tube, the space between the two being filled with the mixture of carbon and manganese peroxide. In the centre of all is the zinc rod. The cell is filled with the usual electrolyte, that in the porous tube being in communication with that which is outside the carbon tube.—E. T.

*Improvements in the Production of Aluminium.* R. E. Green, Southall. Eng. Pat. 5914, April 6, 1889. 4d.

A SUITABLE retort, crucible or furnace is provided having an inlet at its extreme lowest part, to which a porcelain or other pipe which will resist the heat of the furnace is attached and fixed, the joints being well luted up with a fire-resisting substance, such as a paste made of plumbago. This pipe is then connected to a supply of coal gas or other carburetted hydrogen or hydrogen gas. The size of this pipe for a charge of material of a quantity up to 2 cwt. need not be more than half an inch diameter. Broken bits of charcoal, coke, or other refractory substance are then placed at the bottom so as to cover the opening of the gas inlet and prevent its being stopped up during the subsequent operations. Upon this charcoal is placed fluoride of aluminium or the double fluoride of aluminium and sodium or potassium mixed with silica, silicate of soda or potash, or other compound of silicon, and finely powdered charcoal, and upon the top of this mixture is placed a layer of freshly burnt lime, though this is not absolutely necessary to the success of the process. The furnace is subjected to a red heat for an hour with the gas supply turned on. The decomposition being completed, the gas supply is shut off

and disconnected. The slag being removed, the whole is allowed to cool, when the greater part of the aluminium will be found mixed with and absorbed by the charcoal or coke at the bottom of the furnace. A quantity of aluminium of inferior quality remains mixed with the slag, which may be separated by grinding the slag and subjecting it to a second heating under the same conditions as above described.

—A. J. S.

*Improvements in Thermo-Electric and Furnace Batteries.* C. Hudscr, London. From H. Mestern, Munich, Germany. Eng. Pat. 11,661, July 22, 1889. 8d.

THE negative metal of each element consists of a short cylinder of cast iron, furnished at one end with a square base and at the other with a metal tube screwed on it. This tube is conical and holds in place a hollow asbestos block, into the interior of which, and in close contact with the iron, is poured the positive metal (antimony, zinc or alloys) in a molten state. A conducting strip passes out of this positive metal at the top, and curves round to join the next element at its iron end. The latter may be split, the conducting strip being placed in a channel between the two halves, which are then fastened together by screws passing through a common base piece. Rows of elements may be held by their square bases in a suitable frame, with the help of a fireproof cement. Two such frames are placed parallel with the iron ends facing, and heated at these ends by hot furnace gases passing between them to suitable flues. The antimony ends of the elements are kept cool by currents of cold air circulating over the reverse faces of the frames.

—E. T.

*Improvements in "Secondary or Electric Storage Batteries."* H. H. Carpenter, New York, U.S.A. Eng. Pat. 16,241, October 15, 1889. 6d.

THE electrode resembles a broad machine belt passing over two long rollers of small diameter, one at top and one at bottom, the space between the two sides—which are perforated with numerous holes to allow the liquid to permeate—being occupied by tablets of the active material. Cerussite is preferred for the active material for cheapness' sake, being found native, in a pure state. The plates are held in position by a central bolt passing through all, washers being interposed between the separate plates.—E. T.

*Improvements in and connected with Plates for Primary and Secondary Batteries.* I. B. Entz and W. A. Phillips, Schenectady, U.S.A. Eng. Pat. 18,365, November 18, 1889. 6d.

THESE plates are formed by weaving around a flexible copper wire a network of finer copper wire, in the meshes of which a metallic oxide or salt may be embedded. Any suitable length of these netted wires may then be bent round into the required shape.—B. T.

*An Improved Electrode for Secondary Batteries or Accumulators.* G. M. Cruikshank, Glasgow, Scotland. From W. A. Johnson and J. N. Smith, Toronto, Canada. Eng. Pat. 18,953, November 26, 1889. 6d.

EACH electrode is composed of a number of narrow lead plates, dovetailed together at the edges and fastened at their ends to suitable end-pieces. Each plate is provided on each face with a number of longitudinal grooves, preferably of J-shape, like the grooves in the beds of planing and other machines. The edges are burred inwards at intervals so as to divide each groove into short lengths. The plates are pasted as usual. They may be supported from the top of the cell by projections on the end-pieces.

—E. T.

*Improvements in Primary or Galvanic Batteries.* O. A. Enholm, New York, U.S.A. Eng. Pat. 18,966, November 26, 1889. 6d.

Porous partitions are used of a conducting material such as dense carbon in order to lower the resistance of the battery. Positive electrodes of zinc are used, and negative ones of carbon, these latter being made in the form of cups, in which the strong acid is placed, which percolates through the cup into the surrounding liquid to replenish it.—B. T.

*Improvements in Secondary or Storage Batteries.* W. F. Smith, Philadelphia, U.S.A. Eng. Pat. 18,989, November 26, 1889. 6d.

THE stout metallic border of the plate is cut through at places to allow of expansion of the active material, the cut portions being joined by metallic loops (resembling in shape the handles of carpet bags). The containing cells are provided with internal ridges, on which the plates rest by some of the above-mentioned loops.—E. T.

*Improvements in Electrical Secondary Batteries.* J. K. Pumpelly and F. D. Thomason, Chicago, U.S.A. Eng. Pat. 19,883, December 10, 1889. 8d.

HORIZONTAL electrodes are employed, preferably perforated and "pasted" in the following way:—A porous pad is temporarily placed below the plate, the perforations are then filled with dry commercial lead peroxide, and the plate charged in a suitable electrolyte. The time of preparation and forming is said to be in this way much reduced. The plates, with the porous pads removed, are placed in position in their cell, with cellulose fibre filling all spaces round and between the plates, to prevent the electrolyte from easily spilling and to keep the plates free from buckling.—E. T.

*Improvements in or relating to Electrical Batteries.* W. P. Thompson, Liverpool. From M. W. Parrish, Detroit, U.S.A. Eng. Pat. 19,889, December 10, 1889. 6d.

THE materials employed are a lump of crude graphite and zinc as the two electrodes, and salt and water as the electrolyte. It is stated that the cell is very powerful, and that "the zinc electrode cannot be depolarised, even if it comes into direct contact with the graphite."—E. T.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

*The Examination of Commercial Glycerin.* J. H. Wainwright. J. Amer. Chem. Soc. **11**, 125—130.

See under XXIII., page 331.

*Analysis of Marine Oils.* R. W. Moore. J. Amer. Chem. Soc. **11**, 155—158.

See under XXIII., page 331.

### PATENTS.

*Improvements in the Manufacture of Soft Soap for Laundry, Cleansing, and other Purposes.* J. Gott, Manchester. Eng. Pat. 16,845, November 20, 1888. 4d.

To ordinary soap dissolved in water, ordinary petroleum lamp-oil and borax dry soap are added.—W. L. C.

*Improvements in the Manufacture of Soaps and Cleansing Compositions.* R. Stone, London. Eng. Pat. 18,782, December 22, 1888. 4d.

SLATE-REFUSE, marble, or shale, ground to a very fine powder, is mixed with tallow, soap, oil, or other greasy substance, or even with Devonshire or china clay.—W. L. C.

*Improvements relating to the Purification of Fatty Substances, and to Apparatus therefor.* H. H. Lake, London. From "La Société Anonyme des Parfums Naturels de Cannes," Paris, France. Eng. Pat. 18,852, December 24, 1888. 6d.

IN the case of fatty substances extracted by volatile solvents, there is usually much difficulty in completely driving off the last traces of solvent from the fat. The patentees claim to effect this very completely by injecting steam in small jets through the fatty matter, and connecting the condensing apparatus at the same time with an air-pump, so as to maintain a good vacuum.—W. L. C.

*Improvements relating to the Purification of Fatty Substances and to Apparatus therefor.* H. H. Lake, London. From La Société Anonyme des Parfums Naturels de Cannes, Paris, France. Eng. Pat. 18,857, December 24, 1888. 6d.

THE last portions of solvents used in extracting fatty substances are difficult to remove from the fatty matters themselves, and the following method is claimed to facilitate this separation. A vertical boiler with a double bottom, through which steam can be passed, is rendered partially vacuum, and has introduced into it a quantity of water varying with the requirements of each case. It is then heated by turning on the steam, and the mixture of fat and solvent to be separated is injected through a horizontal coil pierced with numerous small holes, situated at its upper end. The steam arising from the heated water mixes with the spray thus produced, and carries away the solvent in the direction of the exhausting pump, on the way to which it passes through a worm and is condensed.—B. B.

*Improvements in Lubricants.* W. McLay, Wandsworth. Eng. Pat. 1501, January 28, 1889. 4d.

LUBRICANTS containing mineral wax are rendered more efficient and more economical in use by being incorporated with a strong aqueous solution of soap, e.g., one part of soap, containing 63 per cent. of fat, with three parts of water.

—W. L. C.

*Improvement in the Manufacture of Lubricants for Machinery.* O. Jeyes, Birmingham. Eng. Pat. 1857, February 2, 1889. 4d.

"REFINED naphthaline" is added to tallow alone or to a mixture of tallow and mineral oil.—W. L. C.

*Improvements in Lubricating Compounds.* H. Morgan, Blairstown. Eng. Pat. 2136, February 12, 1889. 4d.

PARAFFIN wax and French chalk are heated with any mixture of animal, vegetable or mineral oils.—W. L. C.

*A New Ointment.* J. Taylor, Isle of Wight. Eng. Pat. 2471, February 12, 1889. 4d.

IN addition to the usual lard, sweet oil, and beeswax, this ointment contains palm oil, oils of the liver of cod and sting-ray, and red oxide of mercury, all in specified proportions.—W. L. C.

*Improvements in the Treatment of Used Soapy Liquors.* W. G. Reid, Galashiels. Eng. Pat. 4367, March 13, 1889. 6d.

THE waste soapy liquors from the washing of wool or similar material are run into a settling tank for the deposition of the suspended matter, and thence into a vessel where they are treated with lime, and sometimes with a small quantity of some magnesium salt, such as the carbonate (dissolved by excess of carbonic acid) or oxalate, and an alkaline aluminate. The mixture is agitated by blowing in air or furnace gases, and if the lime be in excess it is removed from solution by adding a sufficiency of the original soapy liquor. The desired result is to leave all the alkalis in solution as hydrates, so that the clear liquid can be used for scouring once more, either direct or after treatment with carbonic acid, to avoid injury to the materials to be scoured, by caustic alkali, while the lime is left in the sludge combined with fatty acids. This residue can be utilised for manure, or for making gas, oil or soap. If the recovered liquors become too concentrated, owing to the alkali introduced into them by the wool itself, a portion may be evaporated, and the alkali obtained. In the presence of ammonium salts the ammonia may be recovered by distillation. Sulphates, if in quantity deemed injurious, may be precipitated by a barium salt.—B. B.

*Improvements in or appertaining to the Manufacture of Soap.* W. G. Smith, Kingston-on-Thames. Eng. Pat. 5353, March 28, 1889. 4d.

TURPENTINE and ammonia are incorporated with yellow soap on its removal from the copper.—W. L. C.

*Improvements in Treating Cotton-Seed Oil Mucilage to obtain Soap.* L. Pearson, Glasgow. Eng. Pat. 5622, April 2, 1889. 4d.

IN refining cotton-seed oil by means of alkali, a mucilaginous residue, formed by the action of the alkali on the impurities present in the oil, is obtained. The patentee heats this with close steam, and when liquid, adds a strong solution of caustic soda, or solid caustic soda if the mucilage be dilute, to the extent of about 100 lb. per ton. Open steam is then blown into the mixture for a short time. After shutting off the steam and allowing the liquid to remain at rest, a crude soap collects at the surface, being thrown up by the strong caustic alkali. Should this effect be delayed, the addition of more caustic soda (solid or in concentrated solution) will determine its occurrence. The soap may be bleached with a hypochlorite, and finished by any usual process.—B. B.

*An Improved Dry Soap or Washing Powder.* W. Hepworth-Collins and W. J. Smith, Bolton-le-Moors. Eng. Pat. 17,741, November 7, 1889. 4d.

TO the ordinary dry soap or washing powder of commerce, salts of sodium and potassium are added, the latter in the form of carbonate, nitrate, sulphate or chlorate.—W. L. C.

*A Disinfectant and Detergent Dry Soap or Washing Powder, or Soap Extract or Essence.* W. Hepworth-Collins and W. J. Smith, Bolton-le-Moors. Eng. Pat. 17,742, November 7, 1889. 4d.

MANGANATE of potassium, sodium, or calcium is incorporated with dry soap, or with any solid or liquid preparation thereof.—W. L. C.

*A New Method of Thickening Linseed Oil.* C. H. Robinson, Philadelphia, U.S.A. Eng. Pat. 18,046, November 12, 1889. 4d.

THE reagent employed is the thick gummy mass produced when linseed oil is boiled with litharge and exposed in films to air, in the first stages of the manufacture of linoleum.

One part of this is added to eight of raw oil, and the whole heated to 350° F., until the gummy mass is completely dissolved. The temperature may then be raised to about 630°, and if quick drying be required, 1 per cent. of litharge may be added.—W. L. C.

*Improvements in the Treatment or Preparation for Consumption of Soft Soaps and other like Materials.* J. V. Johnson, London. From L. Genevoix, Naples, Italy. Eng. Pat. 18,592, November 20, 1889. 4d.

TO prevent waste, the soap is wrapped in a covering or bag of some very porous material, usually woven, the size of the meshes or interstices of which depends on the thickness or fluidity of the soap. The covering may even be wholly or partially metallic; in fact, any material may be used which will retain the soap-paste, and yet allow it to exude as required. The invention may be applied also to powders.

—W. L. C.

*A New or Improved Method for Sweetening Margarine, Butter, and other Oils and Fats.* P. Heinz, Frankfurt-on-the-Main, Germany. Eng. Pat. 19,158, November 28, 1889. 4d.

See under XVIII. (A.), page 319.

*An Improved Process for the Extraction of Fats and Oils from Substances containing the same by Means of Sulphurous Acid.* W. Grills and M. Schröder, Neunhüll-Hamborn, Germany. Eng. Pat. 19,948, December 11, 1889. 4d.

THE patentees have found that liquid sulphur dioxide is a good solvent for fats and oils, quite comparable with carbon disulphide and light petroleum. It is true that it does not mix with fats in all proportions, but if the fat be in excess thorough mixture is obtained; otherwise, the mixture separates into two layers, the upper consisting of the oil with defect of sulphur dioxide, the lower of the heavier sulphur dioxide relatively poor in oil. The process of extraction is similar to that generally adopted, and is carried out at 30°–40° C., the chief difference being that to retain sulphur dioxide in the liquid condition at this temperature a pressure of about six atmospheres is needed. A systematic method of extraction may be adopted, or the following simpler plan:—The material to be extracted is placed on a grating or perforated plate in an iron cylinder, at the bottom of which is a steam coil. Liquid sulphur dioxide is now admitted below the grating and heated by the steam coil, the whole apparatus being closed gas-tight. The vaporised sulphur dioxide rises through the material to be extracted, partly condensing there, and partly in a worm above it (which is of course closed at its upper end), and drips back into the lower part of the cylinder charged with the fatty material it has dissolved. This process is continued for hours or days as may be necessary, when the exhausted material is removed, and the sulphur dioxide distilled off from the fat it holds in solution, the last portions being removed by blowing in air or steam; in the latter case the apparatus must be lead-lined, wet sulphur dioxide acting on the iron.—B. B.

*Improvements in and relating to the Manufacture of Soap.* W. Rödiger, Magdeburg, Germany. Eng. Pat. 20,237, December 16, 1889. 6d.

THE patentee states that the difficulties hitherto experienced in making a hard soap from rosin or from mixtures rich in rosin, arise from the varying and considerable affinities for water possessed by resinate of soda made from rosins of different qualities. He partially dehydrates and hardens rosin soaps by the addition of soda-ash, the proportions and conditions of application varying with the circumstances of

each case. As an example of his process the following will suffice:—To 40 parts of a solution of caustic soda of about 30° B., 100 parts of rosin are added, and soda ash in quantity determined by experiment (e.g. 10 per cent.) thrown in to effect the hardening spoken of above; if the action prove sluggish it can be hastened by raising the temperature, and in the contrary case retarded by cooling. The mass is well stirred, put into small "forms" holding about 200 lb., and the stirring continued until the hardening is complete, as is the case in from a few minutes to three-quarters of an hour according to the quality of the rosin. The addition of about 5 per cent. of salt promotes the hardening. The process is applicable to soaps containing fat as well as rosin if the proportion of the latter exceed 50 per cent.—B. B.

#### Improvements in Self-Lubricating Compositions for the Manufacture of Bearings, Cog-Teeth, and other Articles.

P. H. Holmes, Gardiner, Maine, U.S.A. Eng. Pat. 20,433, December 19, 1889. 4d.

WOOD or vegetable fibre is mixed with plumbago made into a paste with water; in some cases a little sulphuric acid and size are added. The product is moulded into eggs, journal boxes, or other articles subject to friction in use.

—B. B.

### XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

#### The Future Supply of India-Rubber. Industries, 8, 187.

THE work of collecting the crude rubber juice has been left till recently to ignorant natives, who have destroyed millions of trees either by cutting them down or by their injudicious system of tapping. Latterly, however, the province of Amazonas has passed laws to regulate the season for tapping the trees, and awarded premiums to encourage the planting of new forests.

Some twenty years ago the importance of the question of the future supply of rubber was recognised by our Government, and James Collins, of Edinburgh, was instructed by the India Office to draw up a report concerning the rubber trees of America, and to ascertain whether they could be grown in India. The results of his investigations were published in 1872. In 1875 Robert Cross, of Liverpool, in concert with C. R. Markham, of Assam, went to Panama to collect seeds and cuttings of the Central American rubber tree (*Castilloa*). He was also sent by the India Office in the following year to Pará to collect information about the Pará (*Hevea*) and Ceara (*Manihot*) trees, which produce the best rubber. The descriptions given in his official report show that he met with formidable difficulties in the course of his undertakings, but he succeeded in his main object. The seeds and cuttings which he obtained were duly sown and planted at Kew, and in due time dispersed over various botanical gardens in India and the Colonies. As trees, they are now flourishing at Madras, Calcutta and Zanzibar, also in Burma and Ceylon. The great superiority of the Pará rubber (*Hevea*) over all other kinds has ensured for it the most attention, but its cultivation has been very much of a failure, notably in Assam and Northern India, though not equally so in Burma and Ceylon. It requires an equable moist climate without extremes of temperature. The *Castilloa* tree was reported a few years ago to be doing well in Burliar and other places in Southern India. Some attempts have been made to grow the West African tree (*Landolphia*) in India. It is a hardy shrub but takes up a good deal of room and the quality of its products leads to some doubt whether it would pay for cultivation. The following is a short list of plants producing india-rubber.

Nat. Order.	Genus.	Species.	Locality.
<i>Euphorbiaceæ</i>	<i>Hevea</i> .....	<i>H. Braziliensis</i>	Para.
	<i>Manihot</i> .....	<i>M. Glaziovii</i> ..	Ceara.
<i>Artocarpacææ</i>	<i>Castilloa</i> ....	<i>C. Elastica</i> ....	Central America, West Indies.
	<i>Ficus</i> .....	<i>F. Elastica</i> ...	Assam, Rangoon, Java.
<i>Apocynacææ</i> ..	<i>Hancornia</i> ..	<i>H. Speciosa</i> ...	Pernambuco,
	<i>Urceola</i> .....	<i>U. Elastica</i> ....	Borneo.
	<i>Vahia</i> .....	<i>V. Gummifera</i> ..	Madagascar.
	<i>Landolphia</i> ..	Various.....	West Africa, Mozambique.

The above trees are to be met with in a broad zone parallel to the equator, where there is an isotherm of 70° F.

Turning from the consideration of trees as they grow in untended nature to those that have been acclimatised, a report in 1881, by Dr. King, of the Calcutta Botanical Gardens, stated that the Ceara tree was the only one that promised good results, while the Pará and the Madagascar had utterly failed. This experience has been confirmed by Sir John Kirk, Consul at Zanzibar, who, in one of his official reports in 1882, said that the Ceara (*Manihot*) plants grew very well even in the worst soil, needed no attention, and commenced to yield rubber in five years, though not in a way to be remunerative. In October 1882, Dr. Trimen, of the Ceylon Botanical Gardens at Peradenya, sent to Kew a sample of the Central American rubber (*Castilloa*) produced from a cutting sent from Kew in 1876. This was examined by an expert, and reported to be of good quality, only deficient in tensile strength, owing perhaps to the immaturity of the tree from which it was taken. Colonial rubber is often being received at Kew, and submitted for examination, showing that this branch of economic botany is far from being neglected. Of Pará rubber from a Kew cutting, grown at Mergui, the first sample was received last season at Kew. As in the above case, it was found wanting in tensile strength, and fell short of the best qualities of ordinary smoked Pará. It remains to be seen whether the excess of its viscous over its fibrous constituents will be corrected in future tappings. It is not only in acclimatising foreign trees in India that work has been done, but, acting on Collins' report, the India Office has caused denuded districts to be replanted with the indigenous *Ficus elastica*. Already in 1870 there was a plantation of these trees at Chardnar, in the district of Darrang, which covered a space of eighty square miles. This particular area has since been annually increased, and there has been planting in other districts besides. It therefore appears that the wanton destruction of rubber trees has practically ceased, and that the importance of securing an adequate supply of rubber for future needs is fully recognised.

The financial side of the question can hardly be discussed till more reliable data have come to hand, but they are hardly likely to prove that undertakings in forestry bring any immediate or very early return. Dr. Trimen, for his part, feels confident that produce from Ceara trees will furnish an important item of revenue to Ceylon. It must be added that, in view of the competition in the case, other interested parties are not so sanguine of commercial success as he is.—O. H.

#### The Use of Coal-Tar Colours in the Manufacture of Pigments for Painters, &c. George H. Hurst. J. Soc. Dyers and Colourists, 1890, 32—36.

FOR some years past there have gradually come into extended use among painters, paper stainers, and calico printers, a class of pigments known as aniline lakes. Many of them find a large sale under a variety of names, such as Vermilionette, Royal reds, Post Office red, Victoria red, Emerald green, Non-poisonous greens, &c.

Perkin, in 1862, patented a process for making pigments from such colours as were then known, by precipitating them with arsenite of alumina, and boiling the precipitate with water. Messrs. Roberts, Dale, & Co. have also patented a process for preparing aniline lakes. They first make a

decoction of fustic, catechu, or quercitron; precipitate this with tin or alumina, and then mix the precipitate with aniline colour as long as it is absorbed—thus, for maroon they give the following: 100 gallons quercitron bark liquor at 1.06 (12° Tw.), 100 gallons of water, and 1 gallon perchloride of tin at 1.6 (equal 120° Tw.). The precipitate is then mixed with 8 lb. of aniline red. Other colours can be made by the same process, substituting other colouring matters for the red.

A lake is a pigment produced from natural colouring matters, such as cochineal, Brazil wood, and similar products, by extracting the colouring principle and combining this with a metallic base like alumina, oxide of tin, &c., so as to form an insoluble coloured pigment. Most of these lakes are true chemical compounds of the colouring principle, and the base—as, for example, Carmine, which is made from cochineal by precipitating the colouring principle, carminic acid, by means of alumina, so that carmine may be regarded as carminate of alumina. Crimson and scarlet lakes are similar in their composition. These lakes are, however, expensive bodies, and some cheaper lakes were made—as, for example, Rose pink and Dutch pink, by adding a quantity of white base, such as whiting or barytes. The shade of the lakes was paler and the tone duller, but they were cheap, and hence were largely used, especially by paper stainers.

The aniline lakes possess certain analogies to the lakes proper, inasmuch as they are or should be insoluble compounds of the colouring matter with a reagent; but they are not true lakes, inasmuch as some diluting agent is always present. The aniline lakes that were first made were not lakes at all, but simply a white base stained with colouring matter. Now, such a pigment cannot be satisfactory in use, for various reasons, one being that the colour, which is not properly fixed, is easily washed out.

A pigment must be insoluble in water and other bodies which are likely to be used as paint vehicles. Now, the most essential property of a coal-tar dye is that it must be soluble in water, and the problem to be solved is to find a body which will form, with the colour or dye, a compound which is insoluble in water. Such a compound could, without any impropriety, be called an aniline lake, but such a body is not suitable for use as a pigment, inasmuch as it has not sufficient body or covering power, and, moreover, would be costly. To get over these defects it is necessary to add some cheap white "base," such as barytes, China clay, or gypsum, which at once gives the desired body and cheapness.

The best method of producing this coloured aniline lake is by a process of precipitation, and all commercial pigments made from coal-tar colours are thus produced.

Necessarily the precipitating agent will vary with the properties of the colouring matters themselves. As a matter of convenience, those colouring matters derived from coal tar which are available for the manufacture of lakes, are divisible into three groups, as follows:—

I. *Basic Colouring Matters*, such as Magenta, Brilliant green, Violet, &c. The members of this class of colouring matters are precipitated by weak organic acids, such as tannic acid and picric acid; as a rule they are not precipitated by mineral acids or salts.

II. *Acid Colouring Matters*, such as the azo dyes derived from naphthols, naphthylamine, &c., which are precipitated by acids and various metallic salts from their solutions. The best precipitating agents for this class of dyes are lead acetate, barium chloride, and aluminium sulphate.

III. *Adjective Colouring Matters*, such as alizarin, gallein, cerulein. These approach more nearly the natural colouring matters in their properties, and they require metallic oxides, such as those of aluminium, chromium, iron, &c., to form lakes, and with these oxides they enter into true chemical combination, forming the coloured body. As a rule, the members of this class of dyestuffs have no, or but little, colour of themselves, and they produce different colours according to the metallic oxide with which they are combined. It is difficult to make very good lakes with them.

An aniline lake consists essentially of three constituents:—1st, the colouring matter; 2nd, the base; 3rd, the precipitating agent.

The Base is a most important constituent. A great deal of the usefulness of the finished product depends upon its quality. As bases the following may be used:—Barytes, China clay, gypsum, and zinc oxide. Starch has been used, but it is not satisfactory. The base should be quite neutral in its properties, and have good body or covering power. Barytes is mostly used, but it is not wholly satisfactory; the common qualities are usually rather gritty. The precipitated varieties known as "blanc fixe" are better and finer, but more costly. The best lakes the author ever made were those with precipitated barytes as base formed in the process of manufacture, but the cost was an item of consideration and would prevent this process from being much used. Gypsum is in some respects a better base than barytes, although it suffers from not possessing sufficient body. China clay gives good results, but is apt to give chalky lakes. Zinc oxide gives good results, but its cost is against it.

The best base for aniline lakes is a mixture of barytes, gypsum, and China clay. Weight for weight, barytes gives the deepest lakes, or, in other words, it takes less colouring matter to produce a lake of a given shade with barytes than it does with any of the other bases; and hence it costs less to make a given weight of a barytes lake than it does for a China clay lake, but on the other hand its covering power is also less.

As precipitating agents may be used tannic acid, picric acid, lead acetate, barium chloride, and aluminium sulphate. The following table gives the behaviour of a number of colouring matters with these agents:—

1. *Colours Precipitated by Tannic Acid*.—Magenta, Aniline blue, Brilliant green, Methyl green, New green, Nile blue, Rhodamine, Safranine, Phosphine, Chrysoidine, Bismarck brown, Paris violet, Methyl violet, Hofmann violet, Quinoline yellow, Auramine.

These belong to what are known as the basic aniline colours. The author found it best to use tartar emetic along with the tannic acid, as its use made the resulting pigment brighter in shade and more insoluble than if the tannin were used alone. One fault with the pigments made with tannic acid is that they do not dry well when mixed with oil; the cause lies with the tannic acid, which has the curious property of retarding, if not entirely preventing, the proper drying of the oil. Tannic pigments are therefore not suitable for oil paints; but for water paints, such as are used by paper stainers and calico printers, they are quite suitable.

2. *Colours Precipitated by Picric Acid*.—Auramine, Night blue, Methyl blue, Methyl green, Brilliant green.

Picric acid lakes are not suitable for oil colours; they dry even more slowly than tannic acid lakes.

3. *Colours Precipitated by Lead Acetate*.—Scarlet BB (precipitate of a poor shade), Mandarin G, Orange G, Orange IV. (gives brownish shade), Fast scarlet 3 R, Acid mauve B, Yellow N (very good precipitate), Croceine orange, Fast red T, Alkali blue, Citronine O, Methyl yellow, Citronine A, Tropaeoline OO (very pale shade), New yellow, Scarlet G, Ponceau 2 R, Scarlet R, Fast violet (this is not of a good shade), Orchil brown B, Fast red A, Azo-yellow, Double brilliant scarlet 2 R, Indian yellow, Crocein 3 B, Quinoline yellow, Crystal scarlet 6 R, Phosphine scarlet OO, Scarlet GT (very good precipitate), Vermilline scarlet KK, Bordeaux S (very good precipitate), Eosines.

(Since different makers use the same name for different colouring matters, it does not follow that the ponceau, for example, of one maker will be precipitated equally well as the ponceau of another maker.)

4. *Colours Precipitated by Sulphate of Alumina*.—Scarlet BB (gives rather brownish precipitate), Mandarin G, Orange IV., Fast scarlet 3 R, Croceine orange, Alkali blue, Victoria blue B, Citronine O, Scarlet G, Fast violet (gives very poor shade), Orchil brown B, Fast red A (too poor a shade to use), Azo yellow, Indian yellow, Scarlet GT.

5. *Colours Precipitated by Barium Chloride.*—Searlet BB, Ponceau, Orange G (fine shade), Orange IV., Fast searlet 3 R (very good result), Acid mauve B, Claret red B, Yellow N, Croceine orange, Crocein, Fast red T, Alkali blue, Victoria blue B, Citronine O, Methyl yellow, Citronine A, Tropaeoline OO (pale colour), New yellow, Searlet G, Ponceau 2 R, Searlet R, Resorein yellow, Fast violet, Orchil brown B, Fast red A, Azo yellow, Double brilliant searlet 2 R, Indian yellow, Crocein 3 B, Quinoline yellow, Crystal searlet 6 R (not a satisfactory shade), Naphthol yellow S, Phosphine, Searlet 2 R, Searlet (GT), Vermilline searlet KK, Searlet 2 RJ (gives fine shades), Searlet 3 R (gives good results).

Of the three last precipitating agents, barium chloride gives the most satisfactory results and the most permanent pigments; then comes sulphate of alumina, although this does not precipitate so many colours; lead acetate precipitates many colouring matters, but lead is rather objectionable in pigments, since if it comes in contact with sulphur it forms the black sulphide, and thus leads to discolouration of the pigment.

The pigments made with acetate of lead, aluminium sulphate, and barium chloride are very satisfactory to use either in oil painting, paper staining, or in calico printing.

The process of making these aniline pigments is comparatively simple. The base barytes, blane fixe, China clay, &c., is diffused through a quantity of water; this requires care, as if not properly done it leads to the formation of white chalky lumps in the finished product. The colouring matter is then added, having been previously dissolved in water; the whole is heated to from 80°–100° C., and the precipitating agent added, the whole being vigorously stirred. The pigment then forms, and on allowing to rest a while settles to the bottom; the top liquor is run off (this should be colourless, or at most have only a faint tint), clean warm water is added, the pigment stirred up, again allowed to settle, the clear top liquor run off, and the washing repeated. The pigment is now put on filter cloths to drain, and is then either sold in paste form for paper stainers and calico printers, or it may be dried for use by painters. The drying must be done at a low temperature. Too high a temperature spoils the shade.

#### VERMILIONETTES AND ROYAL REDS.

These pigments are made with eosines, and were at first used as substitutes for vermilion, hence their name, but they have gradually acquired a position of their own. Vermilionettes at first contained orange lead, but now this enters but little into their composition. Royal reds contain orange lead as their base; this is put in to give them weight and body. The following recipes will be found to give good results:—

	Vermilionettes.			Royal Reds.	
	I. Pale.	II. Deep.	III. Deep.	I. Pale.	II. Deep.
Barytes....	Lb. 100	Lb. 100	Lb. 100	Lb. ..	Lb. ..
Eosine.....	2	6	8	4	8
Orange lead	30	30	..	100	100
Lead acetate	6	16	20	10	20

The yellow shades of eosine give the best results. There are great differences in the quality of eosines; some kinds require more acetate of lead to precipitate them than others. Too great an excess of acetate of lead should be avoided, and every colour maker should ascertain by experiment the proper quantity to be used for the eosine he is working with. By varying the proportions and kind of eosine, a great variety of shades of these pigments can be obtained.

#### SCARLET PIGMENTS.

An immense variety of scarlet pigments may be made by using different scarlets and by mixing these in various

proportions and with other colouring matters, such as oranges and yellows. Hydrate of alumina makes a very good precipitating agent for these scarlets, and gives very fine pigments. The temperature at which they are made should not be allowed to exceed 50° C.

Where blane fixe is used as the base, this may be precipitated concurrently with the colouring matter, and by so doing a finer pigment is the result than if the base were simply diffused through the solution of the colouring matter.

This method may be further extended and hydrate of alumina used in conjunction, whereby very brilliant and deep pigments may be obtained.

*Scarlet Lake.*—110 lb. of sulphate of alumina are dissolved in 100 gallons of water and mixed with a solution of 25 lb. Ponceau RR. The mixture is heated to 60° C., and a solution of 100 lb. barium chloride added; the whole is then heated to the boil, cooled to 60° C., stirring all the time, and then a solution of 60 lb. soda crystals are added.

Care must be taken to avoid an excess of soda crystals as this would affect the shade of the pigment. The addition of the sulphate of alumina to the colouring matter must be made at a temperature not exceeding 60° C., and more especially is this important where those colouring matters are used which are precipitated by sulphate of alumina.

*Yellow Lakes.*—The third class of colouring matters—the so-called adjective colours—such as alizarin, gallein, Resorein green, &c., offer many and special difficulties to the production of lakes. The only one the author has been at all successful with is alizarin, and even with this the lakes made lacked brilliancy. He had not yet succeeded in making a lake from alizarin of the same shade and brilliancy as Turkey-red on cloth. Most of the so-called Turkey-reds that are being sold now are made from the Azo-scarlets.

Dark red lakes of good staining power can be obtained by the following processes:—

1. *Pure Alizarin Lake.*—20 parts of 20 per cent. alizarin are mixed with 250 parts of water, 10 parts of sulphate of alumina previously dissolved in water added, and 2 parts of calcium acetate, the mixture is then boiled for one hour, and 10 parts of soda crystals dissolved in water are added. Boiling is then resumed for some hours, followed by standing for 24 hours, filtering, washing, and drying of the precipitated lake. This yields a fine pure lake.

2. *Alizarin Lake.*—100 parts of barytes are diffused in 500 parts of water, and 20 parts of 20 per cent. alizarin, 10 parts sulphate of alumina, 2 parts of calcium acetate added; the mixture is then boiled well for two hours, stirring thoroughly. After this must be added the solution of 10 parts of soda crystals. Boiling follows for one hour longer, succeeded by standing for the rest of the day. The precipitate is then filtered, washed, and dried. This gives a lake of good colouring power and of a bright ruby tone. If caustic soda be used instead of carbonate of soda as a precipitating agent, the lake assumes a violet tone. By using a little oleine a rather brighter lake can be got, but an excess must be avoided.

Better results are got by the following process, but the time occupied is much longer:—

Take 100 parts of barytes and diffuse through 500 parts of water, add 10 parts of oleine, 10 parts of alizarin, and boil for one hour, then allow to stand for 24 hours, stirring at intervals; then add 20 parts of acetate of alumina (12° Tw.) and 2 parts of acetate of lime, stir well, allow to stand for two days, then boil vigorously for two hours, stirring well all the time; finally add, while still boiling, 5 parts of soda crystals. Filter, wash, and dry the precipitated lake.

Any other base than barytes can be used if thought desirable. Satisfactory lakes have not so far been obtained from other adjective colouring matters; as a rule these produce shades of rather a dull character not wanted in pigment colours.

The pigments thus described are mostly used in the painting trade. A few are used, to a limited extent, in calico printing, but the author is of opinion that in this department there is a wide field for their use in pigment styles, for producing brilliant shades unobtainable from other pigments.

In the discussion which followed, Dr. Knecht, referring to the precipitation of the eosin lakes by means of lead salts, asked whether—seeing that the presence of lead might sometimes be objectionable on account of its blackening in presence of sulphuretted hydrogen—no other substance had been used instead. He had himself succeeded in producing an erythrosine lake in the following manner:—A solution of erythrosine was added to a solution of wool in caustic soda, and then just sufficient sulphuric acid for neutralisation. In this manner a brilliant crimson lake was formed, but he had not tried its fastness to light nor its practical applicability. As precipitants for the basic colouring matters, Mr. Hurst had only referred to tannic acids and picric acids. There was another large class of precipitants which might be used, viz., the direct cotton dyes generally known as the benzidine dyes. A very wide range of shades might be obtained by using them. He understood that the same principle was employed pretty extensively in cotton dyeing, viz., topping colours produced with direct dyes, with basic ones, either for the purpose of intensifying the shade or altering it. Liechi and Suida, he believed, had succeeded in producing a brilliant Turkey-red lake by combining in suitable proportions, alizarin, alumina, lime, and Turkey-red oil. The red lake obtained by Müller-Jacobs' method ("Resinate lakes") was not likely to be brilliant, since the lime which is an essential constituent of Turkey-red was wanting (this Journal, 1889, 770).

Mr. H. Crossley thought that some of these coal-tar lakes were well worth the attention of designers in place of those produced by lead acetate.

Mr. Hurst, in reply, said that he had found that alum would precipitate some colouring matters which lead would not. He had found that the temperature of 180° F. was the best to use in producing these lakes, and the one at which the brightest colours were obtained. The reason why he had given empirical quantities of lead acetate for precipitating the eosins, instead of the theoretical ones, was because the eosins of commerce varied so much in their strength. Experience had shown that alum was not a good precipitant for the eosins, and he regarded the sulphuric acid contained in it as the reason, it being too strong an acid. He agreed with Dr. Knecht that the reducing action of the tannic acid was probably the cause of the slow drying of lakes produced from basic colouring matters. He was not favourably impressed with the use of the benzidine colours as precipitants; only some of them—viz., the yellow—could be used, because the others were not fast to light. Vermilionettes stood light well as oil paints if varnished over. The Manchester Tramway Company used them for their cars, and had found them to stand very well. The author agreed that the term "diluent" was preferable to that of "base," but used the term "base" because it was better understood by the practical painter.

#### PATENTS.

*Improvements in the Manufacture of Waterproof Material for Bags and other Articles.* R. Stone, London. Eng. Pat. 16,400, November 12, 1888. 4d.

BAGS made of hemp, flax, tow, cotton, or any fibrous or other material, or wire netting, are coated with a mixture of shale, tar, china clay, boiled linseed oil, terebine, and oak varnish.—E. J. B.

*Improvements in the Manufacture of Linoleum and like Fabrics.* H. W. Godfrey, C. F. Leake, and C. E. Lucas, Staines. Eng. Pat. 18,110, December 11, 1888. 8d.

This invention relates to a process for manufacturing linoleum and similar fabrics in such a way that the pattern extends throughout the thickness of the fabric. The process consists in "preparing a block of tesserae arranged in accordance with the pattern and laid one over the other; pushing forward such tesserae layer by layer on to a receiving

surface; advancing the said surface with the tesserae upon it step by step through a press, and consolidating the whole by an intermittent pressure."

The necessary apparatus, which is described, is also claimed.—E. J. B.

*A New or Improved Process and Compositions for Preparing and Coating Canvas, Floorcloth, Linoleum, and other Textile Fabrics.* J. Heyde, Dundee. Eng. Pat. 1758, January 31, 1889. 4d.

THE patent refers to a composition for first coating the fabric under treatment, to a composition for the back, and to another for the front or face of the fabric.

Composition No. 1 is as follows:—

9 parts by weight of extract of Irish moss in a thick gelatinous mass.

2½ parts by weight of strong starch.

7½ parts by weight of clay or whitening.

½ part by weight of brown glycerin.

½ part by weight of glucose.

The whole to be mixed with one-third by volume of water or skim milk; 10 to 12 lb. of alum per ton of above mixture and a little sulphuric acid may be added.

Composition No. 2 for backing the fabric is as follows:—

One part of No. 1, without clay or whitening, for which colouring matter such as oxide, ochre, &c. may be used.

Composition No. 3 for facing the fabric is as follows:—

Same as No. 2, but instead of the backing colour the ground colour must be used.—A. J. K.

*A Process for Waterproofing and Preserving Textures and other Materials.* C. F. Hime, London, and I. H. Noad, East Ham. Eng. Pat. 7715, May 8, 1889. 4d.

THE process consists in treating fabrics with a solution of cellulose in "ammonia-zinc." The latter is obtained as a colourless solution by treating an "ammonia-copper solution of cellulose" with metallic zinc.—E. J. B.

*Improved Materials and Process for Staining and Mottling Wood.* F. T. Prosser and W. Carter, London. Eng. Pat. 19,852, December 10, 1889. 4d.

THE wooden article to be stained, for instance a tennis racket, having had its surface properly smoothed and prepared, is sponged over with a mixture of 1 volume of nitric acid and 2½ volumes of water, and then heated in the flame of a gas-burner till the tint is fully produced. After "papering," the article is sprinkled with whiting wherever it is desired to produce a mottled effect, and is then sponged with a mixture of nitric and sulphuric acids somewhat diluted with water, and heated as before.—E. B.

*Improvements in Preparing the Surface of Iron and Steel in the Form of Flat or Corrugated Sheets, Hoops, Wrought or Cast Plates, Bars, or Manufactured Articles, for the Purpose of Coating it, and in Coating it with Waterproof Material for the Prevention of Oxidation or Rust.* R. C. Jay, London. Eng. Pat. 20,263, December 17, 1889. 6d.

THE iron or steel is exposed to the moisture of the atmosphere for a sufficient length of time to bring the scale off and form a coat of oxide sufficient to eat into the surface of the metal. A quicker method is to place the iron or steel in a bath of muriatic acid in the proportion of one part of acid to five parts of water. After taking out and washing off the acid, the plate is exposed to the action of the atmosphere until a sufficient coat of rust is formed, the process of rusting being assisted by moistening the surface from time to time with water. When the coating of rust is formed the iron or steel is dried at a temperature insufficient to destroy the coating of rust. At this temperature it is then coated with ordinary "gas tar, pitch, or a mixture of the two." Where pitch is employed an addition of treacle or molasses may be made so as to temper the pitch

and render it less brittle. Colours or paint mixed in the ordinary manner with boiled oil or dryers may be used. In some work Aspinall's enamel is used. Tar or pitch, either separately or combined with treacle or molasses will, when mixed with the colours, produce darker shades, which differ considerably from the colours originally employed. A few minutes in the bath is sufficient, when heating in an oven follows, beginning with a low temperature and rising to temperatures depending on the nature of the coating materials, but, as a rule, not falling below 150° F., so that the heat of the sun at least may be easily withstood.

—A. J. S.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

### PATENT.

*A New Extract and its Utilisation as a Dye, Ink, Stain, Tanning Liquor, and the like.* E. Braiser, London, and J. H. Knowles, Hull. Eng. Pat. 2360, February 9, 1889. 4d.

See under IV., page 285.

## XV.—AGRICULTURE, MANURES, Etc.

*Fixation of Nitrogen by Leguminous Plants.* E. Béal. Compt. Rend. 109, 670–673.

In his researches on the fixation of atmospheric nitrogen in the soil by the action of micro-organisms, Berthelot has recognised the part played by the leguminosæ (this Journal, 1889, 626). The root of a leguminous plant can be inoculated by pricking it with a needle which has been introduced into a tubercle of a plant of the same family: tubercles develop rapidly upon the root thus inoculated, and these tubercles are found to be full of bacteria. The present communication describes the effects of two such cultures.

I. Two scarlet runners (which had germinated on wet filter-paper) were inoculated with bacteria from a tubercle growing on a root of *Cytisus*. The two plants were bedded in 10 kilos. of river-gravel which did not contain any appreciable amount of nitrogen. The gravel was watered from time to time with a very dilute solution of potassium chloride and calcium phosphate. The experiment lasted 67 days; the plants developed a number of ripe pods and their roots were covered with tubercles. Analyses and weighings are given showing that the weight of the plants (dried) was 24 times that of the seed from which they had germinated, and that the amount of contained nitrogen was 17 times that contained in the seed. The gravel, which originally contained no nitrogen, was now found to contain 0.0581 per 1,000, or 0.581 gram. in the 10 kilos. Deducting the amount contained in the water (which was certainly less than 0.1 gram.) the results are:—

	Grms.
Nitrogen fixed by the plants.....	1.4872
"      "      the soil.....	0.4810
Total.....	1.9682

The surface of the gravel covered about 0.2 sq. metre; this corresponds to 74.36 kilos. of nitrogen fixed by the plants and 24.05 kilos. fixed by the soil per hectare, or a total of 98.41 kilos.

II. A fragment of lucerne root covered with tuberculous growth was bedded in a flower-pot containing 4 kilos. of sandy soil: the weight of the (dry) root and contained nitrogen was estimated from a fragment of equal weight taken from the same root. The amount of nitrogen in the

soil was estimated before and after the culture, during the course of which the lucerne bore three crops, each of which was separately examined. The following table shows the amount of nitrogen contained in the 4 kilos. of soil:—

	In 100 Parts of Soil.	Total Nitrogen.
At the end of the experiment.....	0.1140	Grms. 4.560
At the beginning.....	0.0525	2.100
Nitrogen fixed by the soil.....		2.460

Thus the amount of nitrogen in the soil was more than doubled. The results also show that the lucerne with its crops contained 80 times as much nitrogen as the original root.

The experiments, like those of Hellriegel, Wilfarth and Berthelot, show conclusively that leguminous plants grow readily on soils which are poor in nitrogen, provided that their roots are furnished with tubercles containing bacteria. They produce abundant crops rich in nitrogen, and by means of their roots they fix nitrogen in the soil. They well deserve the name of *plantes améliorantes* given to them by the farmers.—D. E. J.

*On Air contained in the Soil.* T. Schloesing, jun. Compt. Rend. 109, 673–676.

THE author gives the results of a number of analyses of samples of air taken from the soil by a method previously described by him. The samples were generally taken at two depths in each instance, the one (25–30 cm.) from the soil properly so called, and the other (50–60 cm.) from the sub-soil. One-half of the samples were analysed completely, and were found to consist of oxygen, carbon dioxide and nitrogen without any measurable quantity of combustible gas; in the others the amount of carbon dioxide only was determined. With regard to the 23 samples taken from ploughed land, the author simply states that his results were in general similar to those obtained by Bous-singault and Lévy. There was no lack of oxygen, at any rate at the depth of 50–60 cm.; the amount of carbon dioxide increased noticeably with the depth.

Thirty-nine samples were taken from pasture lands which had not been ploughed for years, and which were therefore expected to yield more carbon dioxide and less oxygen. The analyses given show remarkable variations in the amount of carbon dioxide for the same soil at different dates:—Samples taken in June and September, yielding 3.54 per cent. and 0.9 per cent. respectively in one instance, and 8.8 per cent. and 1.4 per cent. in another. The amount of oxygen varied from 10 per cent. to 20 per cent. In general, the amount of carbon dioxide was found to increase with the depth; in the two cases where this rule was reversed the weather was hot and calm, and the author explains the exceptions as follows:—A period of fresh windy weather, accompanied by changes of barometric height (all favourable to renewal of the internal atmosphere), is often followed by hot close weather. The soil is heated sooner than the sub-soil, and is richer in oxidisable organic matter; as long as the calm weather lasts there is little interchange with the internal atmosphere, so that for a time the air in the soil may contain a larger proportion of carbon dioxide than that in the sub-soil. On the slopes of valleys the proportion of carbon dioxide was found to increase in passing down the slope, as might be expected from the density of the gas. This was even noticeable when samples were taken from places only a few metres distant from each other. The author objects to the phrase "confined atmosphere," usually applied to air contained in the soil, and points out the necessity of recognising its mobility. Gases are in any case more mobile than water, and their movements are assisted by every cause which alters their temperature, pressure, or chemical composition.—D. E. J.

*The Changes which Occur in Plants in Presence of Organic Acids.* L. Mangin. *Compt. Rend.* **109**, 716—719.

DE SAUSSURE has shown that the cactus is distinguished from other plants by evolving oxygen without absorbing carbon dioxide. The author has, however, succeeded in inducing these conditions artificially by injecting into the leaves of the laurel-rose, the lilae, &c., various organic acids, such as malic, citric and tartaric acids. Negative results were obtained with acetic, formic, oxalic and succinic acids. A three per cent. solution was injected into the leaf of the plant, and exposed to the sunlight for 4—5 hours. The author found that malic acid increases the exhalation of oxygen more than citric acid, and citric more than tartaric acid. The amount of oxygen also increases with the concentration of the acid up to a given point, the maximum being 3 to 4 per cent. Placed in the dark, the leaves injected with malic acid exhale a volume of carbon dioxide much greater than the quantity of oxygen absorbed, whereas under normal conditions the reverse is the case. Similar results are yielded with citric and tartaric acids. The presence therefore of certain organic acids produce in the leaf a double phenomenon. In the dark the disengagement of a larger volume of carbon dioxide than that of the oxygen absorbed takes place, and in the light the exhalation of oxygen without any corresponding absorption of carbon dioxide.

—J. B. C.

*On the Exhaustion of Land Cultivated without Manure, and the Value of the Organic Matter contained in the Soil.* P. P. Dehérain. *Compt. Rend.* **109**, 781—785.

COMPARISONS have been instituted between two soils, the one having had no manure for 12 years, the other being fertilised in the usual ways. The latter gave in the year of comparison a weight of beetroot equal to about 35,000 kilos., the former gave from the same area but 11,000 kilos. Experiments have been made on the soils to discover the causes producing such effects. There is no appreciable difference in the amounts of total phosphates or nitrogen, but there is in the case of the organic carbon, thus:—

—	1878.	1888.	Difference.
Lot 21, without manure.....	16.30	7.30	9.00
Lot 32, after dunging .....	16.60	16.00	0.60

As to the part played by the organic constituents of the soil, the following hypotheses have been advanced:—

1. That the humus-like matter acts as a sponge, retaining water throughout the summer for the benefit of the plant.

But it is shown that in 100 parts of earth rich in humus the quantity of water was 18.57, whilst in 100 parts of earth poor in humus there was 17.67.

2. That the production of nitrates and carbonic acid gas is aided by the slow combustion of the organic matter.

Here, again, however, analyses of the two soils show but little difference.

3. That the humus acts like a food to the plants.

That this is the correct explanation the author proved by cultivating beetroots in soils, the one of which contained much humus, whilst the other, though poor in this constituent, contained artificial manures. The differences in favour of the former, of the total weight of the plants, and the percentage of sugar, were most marked.—S. G. R.

*Manurial Experiments with Different Phosphates.* Ullbricht. *Der Landwirt*, **49**, 659—662.

BARLEY (*Hordeum vulgare*) was cultivated in a greenhouse, in glass pots, on sterile sand, to which was added a normal manure, and, in various pots, phosphoric acid in different chemical conditions. Moreover some pots contained, in addition, absorption material, indicated by A. in the table,

consisting of 53.7 grms. of ferric hydroxide, and 80.2 grms. of calcium carbonate, and sometimes humus acid (H. in the table) to the extent of 4.9 grms. The so-called oxyapatite was prepared by heating 3 mols. di-calcium phosphate with 4 mols. calcium carbonate, whilst di-calcium phosphate, heated by itself, gave the calcium pyrophosphate. The author takes these as representing two forms of combined phosphoric acid, whilst he recognises a third form in the free phosphoric acid in many superphosphates. Thomas slag probably contains the first two forms. The following table of results is taken from the more detailed table in the original:—

Proportion of Phosphoric Acid.	Phosphatic Manuring.	With or without Auxiliaries.	Yield in Grms. per Pot.		
			Grain.	Total.	
141.7	Mono-calcium phosphate {	..	10.36	22.85	
		A.	4.19	11.51	
		A. H.	6.62	16.72	
141.7	Free phosphoric acid {	..	10.00	22.91	
		H. A.	7.60	17.82	
		..	6.91	17.33	
141.7	Di-calcium phosphate {	H.	9.05	21.94	
		A.	4.99	11.82	
		H. A.	8.63	20.77	
283.4	Tri-calcium phosphate {	H.	0.28	3.27	
		H. A.	2.61	8.42	
283.4	Tetra-calcium phosphate {	H.	..	2.02	
		H. A.	0.45	3.94	
283.4	Oxyapatite {	H.	5.01	10.53	
		H. A.	8.13	19.86	
283.4	Calcium pyrophosphate {	H.	0.02	1.87	
		H. A.	0.22	5.31	
283.4	Ferric phosphate .... {	H.	0.62	3.75	
		H. A.	5.28	22.19	
283.4	Aluminium phosphates {	H.	6.43	13.44	
		H. A.	10.63	23.97	
283.4	Canadian apatite {	Finest powder {	H.	..	1.31
		H. A.	0.26	3.27	
		Coarse powder {	H.	0.61	1.00
		H. A.	0.17	2.38	
283.4	Thomas slag {	Finest powder {	H.	5.49	13.96
		H. A.	0.70	16.57	
		Coarse powder {	H.	2.68	6.74
		H. A.	4.84	12.42	

Noteworthy is the inactivity of the apatite, the superiority of fine slag over the coarse, the action of the absorbent on the soluble phosphoric acid, and of the humus acid on the di-calcium phosphate.—D. A. L.

*Manuring with Ammonium Sulphate and with Chili Saltpetre.* M. Maereker. *Bied. Centr.* **18**, 724—729.

THE experiments were made in 1888, when the meteorological conditions were as unfavourable as possible. The first series of experiments were made to ascertain the effect of using calcium carbonate as well as ammonium sulphate

for manuring, and the results are shown in the following table:—

	Increase in Kilos. per Hectare.		
	With Lime alone.	With Ammonia alone.	With Lime and Ammonia.
Barley grain .....	107·6	228·9	601·6
Oat grain .....	166·0	613·7	1,653·3
Wheat grain .....	67·0	177·5	237·5
Potato tubers .....	957·8	726·8	1,538·4
Mangel roots.....	720·0	5,420·0	4,640·0
Sugar beet roots .....	— 258·0	+ 2,217·0	+ 2,608·0

All crops, except one experiment with summer wheat, yielded a marked increase with ammonium salts alone, and all, except sugar beet, with chalk alone. Heavier dressings of ammonia yielded still larger crops. This was also the case in the next series of experiments made to ascertain the relative manurial value of ammonium sulphate and Chili saltpetre. For barley, the light dressings were 62·5 lb. Chili saltpetre and 50 lb. of ammonium sulphate; the heavy dressings being respectively 100 lb. and 80 lb. For oats, sugar beet, potatoes, and winter cereals the dressings were 100 and 150 lb. of Chili saltpetre and 80 and 120 lb. of ammonium sulphate per plot of  $\frac{1}{4}$  hectare. Some of the results are as follows, in kilos. :—

Crop.	Light Dressings.		Heavy Dressings.	
	Ammonium Salts.	Chili Saltpetre.	Ammonium Salts.	Chili Saltpetre.
Barley .. { Grain	2,160·0	2,252·0	2,433	2,432
{ Straw	2,831·5	2,938·5	3,159	3,249
Oats .... { Grain	2,628·5	2,591·5	2,916	2,820
{ Straw	4,742·0	4,732·5	5,184	5,235
Potatoes .....	17,450·0	17,349·0	18,709	20,176
Sugar beet .....	40,500·0	40,000·0	43,000	45,900

From these numbers and results obtained in another district it is concluded that light nitrogenous manurings with

either Chili saltpetre or ammonium sulphate have given an equal increase in yield with summer cereals, beets, and potatoes, but that heavy nitrogenous manuring applied to beets and potatoes in form Chili saltpetre has proved superior to the same quantity of nitrogen applied in the form of ammonium sulphate.—D. A. L.

#### Manurial Experiments on Light Sandy Soil. E. Güntz. Bied. Centr. 18, 796.

Six plots on a sandy soil received in 1885 dressings of manures in quantities based on the composition of an average rye-crop. They all of them received five times the indicated quantity of ash constituents, and in addition plots I., II., III., IV. had three times, and plots V. and VI. respectively, four times and twice the indicated quantity of nitrogen. Lupinus were grown in 1886 and 1887, and without further manuring a crop of summer wheat was taken in 1888, with the following results in kilos. per  $\frac{1}{4}$  hectare:

Plots.	I.	II.	III.	IV.	V.	VI.
Grain.....	291·88	235·63	193·38	345·63	336·88	365·63
Straw.....	621·25	572·50	491·25	698·75	675·00	701·25
Chaff, &c.....	42·50	36·12	29·87	40·75	44·25	31·87
Total .....	955·63	844·25	714·50	1,085·13	1,056·13	1,098·75

The low yield on plot III. is attributed to previous special and prolonged manuring with ammonium sulphate, and that on plot II. to previous manuring with lime.—D. A. L.

#### Experiments on Heavy Soil. E. Güntz. Bied. Centr. 18, 797—798.

Saxon white Zwiebel potatoes were cultivated on six plots, each a square ruthe (about 17 square yards) in extent, 66 eyes, weighing 2,860 grms., were sown in two rows on each plot with 625 grms. of Chili saltpetre and 818 grms. of potassium salts, besides which plots III. and IV. had 200 grms. phosphoric acid in 829·6 grms. of Thomas-slag powder, and plots V. and VI. the same quantity of phosphoric acid in 1,844 grms. of animal charcoal superphosphate.

The manures were mixed with fine mould and spread in the furrows. A detailed table of the results is given, from which the following numbers are taken:—

#### “Clover Sickness” and its Remedy. Stand. Agric. Reps. March 1890.

No greater service, in recent times at least, has been rendered to the farmer by the entomologist than that of identifying the cause of the very troublesome plant disease known as “clover sickness.” The frequent growth of clover as a nitrogen-restoring crop is of obvious advantage, and in many parts of the country this is prevented by the disease in question, so that few farmers dare to sow clover more frequently than once in eight years, while on some soils it does not succeed as frequently as that. This subject is referred to in two annual reports on injurious farm insects, just issued, one by Miss E. A. Ormerod, consulting entomo-

logist to the Royal Agricultural Society, and the other by Mr. Charles Whitehead, for the Board of Agriculture. It is dealt with in greatest detail in the former publication, in which the evidence as to the cause of clover sickness being the cecideworm (*Tylenchus devastatrix*) is full and conclusive, confirming that which was obtained in a previous season. Better still, attention is directed to some experiments carried out by Mr. Wilks, a colleague of Sir John Lawes, at Rothamsted, which point to the probable discovery of an effectual remedy for the disease. Last spring, clover sickness was detected in one of the Rothamsted fields, and it appeared to be spreading. On the most diseased portion of the field a dressing of 3 cwt. of sulphate of potash and

1 cwt. of sulphate of ammonia per acre was applied early in April, on another portion 2 cwt. of sulphate of iron, and on a third plot half the quantity of sulphate of iron. By the middle of May it was found that the disease had entirely ceased to exist on each of the first two pieces of land, the clover growing most vigorously, especially on the plot dressed with sulphate of potash and sulphate of ammonia, on which there was not a gap to be seen. At the end of July the good effect of this application was found to have extended to the second crop of clover, while the disease showed no signs of existence on the plot to which 2 cwt. of sulphate of iron had been applied, though it did show itself where only half the quantity was used; but the growth was much more luxuriant where the mixture first named was put on. Mr. John Elder, of Uphall, Linlithgowshire, also cured a crop of clover of the disease in a previous season by the use of sulphate of ammonia and potash. A few more successful trials of the kind would place the effectiveness of this remedy beyond all question.

*Experiments on Grass Land near Reading. Stand. Agric. Reps. March 1890.*

AN account of the financial results of the experiments in the application of various manures to grass land which he has carried out during the last four years, at Dyson's Wood, near Reading, has been issued by Mr. Martin J. Sutton. Unfortunately, this is the final record of these valuable experiments as far as their present location is concerned, as Mr. Sutton has removed to a larger farm in order to find greater scope for his growing herd of Kerry and Dexter cattle. In the pasture, where the results have all along been most trustworthy, the greatest gains have been obtained from the use of certain manures applied twice during the last three years, which have turned out better than dressings applied on another set of plots in the same pasture twice during four years. Two dressings have given practically identical results. The gain per acre during three years from the use of 3 cwt. per acre of dissolved bones amounts to 7*l.* 15*s.* 9*d.*, while that arising out of the application of 1 cwt. of nitrate of soda and  $\frac{3}{4}$  cwt. of muriate of potash is 7*l.* 15*s.* 3*d.* The former of the two dressings is to be preferred, because stimulating nitrogenous manures injure the character of the herbage on permanent pasture. A mixture of 4 cwt. of basic elder, 1 cwt. of nitrate of soda, and 2 cwt. of kainit takes the third place, with a profit of 4*l.* 8*s.* 6*d.*, while for 3 cwt. of raw bone meal a credit balance of 3*l.* 15*s.* 9*d.* is shown, and 10 tons of farmyard manure left a gain of 3*l.* 14*s.* 3*d.* On the plots which have been under treatment for four years, two applications of 3 cwt. of superphosphate and 2 cwt. of kainit proved the most profitable dressing, the net gain for the period being 3*l.* 7*s.* 3*d.* This dressing was one of the most successful in other pastures, and should certainly be included in any future trials. The hay was valued each year at 4*l.* a ton, and the gain is the value of the produce in excess of that from the unmanured plots, less the cost of the manures.

*Experiments on Barley and Grass at Cirencester. Stand. Agric. Reps. March 1890.*

PROFESSOR KINCH has issued a full report of experiments on barley and grass, carried out by him on behalf of the Royal Agricultural College, Cirencester, last season. The mean yield of 10 plots of barley, dressed with 2 cwt. per acre of nitrate of soda, was 40 $\frac{1}{2}$  bushels per acre, as compared with 20 $\frac{1}{2}$  bushels obtained from the unmanured plots, while 14 tons of farmyard manure gave 37 bushels, and half the quantity 27 $\frac{1}{4}$  bushels. A dressing of 3 cwt. of superphosphate and 3 cwt. of kainit gave only 3 $\frac{1}{2}$  bushels per acre over the yield of the unmanured plots, and when these manures were added to nitrate of soda the yield was less than from the latter alone. Less produce was obtained when sulphate of ammonia, containing an equal quantity of nitrogen, was used instead of nitrate of soda. The

results of the grass experiments are as below, the increase being the excess over the produce of the unmanured plots:—

Manures per Acre.	Hay.	Increase.
None .....	Cwt. 23 $\frac{1}{2}$	Cwt. ..
12 tons farmyard manure .....	41 $\frac{1}{2}$	18
2 $\frac{1}{2}$ cwt. nitrate of soda .....	33	9 $\frac{1}{2}$
2 cwt. sulphate of ammonia .....	22 $\frac{1}{2}$	8 $\frac{1}{2}$
5 cwt. kainit .....	22 $\frac{1}{2}$	$\frac{1}{2}$
5 cwt. superphosphate .....	30 $\frac{1}{2}$	7 $\frac{1}{2}$
5 cwt. guano .....	31 $\frac{1}{2}$	8 $\frac{1}{2}$
5 cwt. superphosphate .....	41 $\frac{1}{2}$	18 $\frac{1}{2}$
2 $\frac{1}{2}$ cwt. nitrate of soda .....		
5 cwt. superphosphate .....	36 $\frac{1}{2}$	13 $\frac{1}{2}$
2 cwt. sulphate of ammonia .....		
5 cwt. kainit .....	31 $\frac{1}{2}$	8 $\frac{1}{2}$
5 cwt. superphosphate .....		
5 cwt. kainit .....	37 $\frac{1}{2}$	14 $\frac{1}{2}$
5 cwt. superphosphate .....		
2 $\frac{1}{2}$ cwt. nitrate of soda .....	35 $\frac{1}{2}$	12 $\frac{1}{2}$
5 cwt. kainit .....		
5 cwt. superphosphate .....	39 $\frac{1}{2}$	16 $\frac{1}{2}$
2 cwt. sulphate of ammonia .....		
5 cwt. kainit .....	39 $\frac{1}{2}$	13 $\frac{1}{2}$
2 $\frac{1}{2}$ cwt. nitrate of soda .....		
5 cwt. kainit .....	39 $\frac{1}{2}$	13 $\frac{1}{2}$
2 cwt. sulphate of ammonia .....		

As arranged here, the results of the several dressings of manure may be easily compared. It will be seen that the farmyard manure gave better results than anything except the mixture of superphosphate and nitrate of soda, but not nearly enough extra produce to pay for its cost. The increase from the use of nitrate of soda alone is not very great, and that from sulphate of ammonia is less. Kainit alone gave scarcely any increase, but did well in conjunction with either of the nitrogenous manures, and especially with nitrate of soda. Superphosphate alone did fairly, considering its small cost, and in conjunction with either of the nitrogenous manures it gave a considerable increase. The reduction of yield which took place when kainit was added to the mixture last named is puzzling, and may have arisen from difference of soil. In every comparison nitrate of soda alone, or in combination with other manures, beats sulphate of ammonia. In relation to these experiments, however, it is desirable to point out that the application of nitrate of soda or sulphate of ammonia—especially the former—while increasing the yield of hay for one season, deteriorates the herbage, whereas superphosphate and potash (in kainit) improve it.

PATENT.

## XVI.—SUGAR, STARCH, GUM, Etc.

*Invertase and the Inversion of Cane Sugar.* F. W. Tompson. Trans. Laboratory Club, 2, 63—71.

Most plants and animals are able to make use of cane sugar as a food material. Now it has been shown that cane sugar injected into the blood is removed unchanged by the kidneys, and that yeast is quite unable to ferment a solution of cane sugar if a small quantity of potash be present, which destroys its inverting action; whilst, on the other hand, when the cane sugar is first inverted, it rapidly disappears from the blood without elimination by the kidney in the first case, and is quickly and completely fermented in the second. It is thus evident that cane sugar, as such, is not assimilable, but requires to be inverted for use as a food. It has been found that the small intestine of man and the higher animals possesses this property of inversion, as also do all varieties of yeast yet examined.

The sugar cane and beet store up cane sugar as a reserve material; they have no power of inverting it during the first stage of their growth, but during the second (flowering and fruiting) this property is present in a marked degree.

The common method of artificially inverting cane sugar is by the action of dilute acids. Invertase may be used for this purpose; it is prepared from yeast by pounding with sand, washing the broken yeast cells with water and precipitating the filtered washings with alcohol, when a syrupy precipitate is obtained which may be dried and powdered; it is called invertase or invertin, although it probably contains only a small amount of the pure ferment. The published analyses of this body vary greatly. It has no action on any other carbohydrate than cane sugar, which it hydrolyses into a mixture of levulose and dextrose, commonly called invert sugar. Alkalis destroy this action; very dilute acids (1:100,000) increase the action, but quantities only slightly greater destroy it. It is able to invert many times its weight of cane sugar and is probably not destroyed by so acting. The rapidity of the inversion increases with the temperature, being most active at 160°—170° F., but a slightly higher temperature destroys it. As the vitality of the yeast cell is destroyed considerably below the temperature of greatest activity of the invertase, the author has utilised this fact in a patented process for inverting sugar commercially, first heating the cane sugar solution to 160°—170° F. and then introducing the yeast, whereby all fermentative power is destroyed whilst the inverting power is unimpaired. After standing some hours the sugar is completely inverted.—A. L. S.

*Xylose.* H. J. Wheeler and B. Tollens. *Annalen*, 254, 304—320.

This second pentaglucose,  $C_5H_{10}O_5$ , is obtained from wood gum (Holzgummi) by hydrolysis, the yield amounting to about 33 per cent. It crystallises in needles melting at 145°, about 10° lower than the isomeride, arabinose. Its specific rotation is (+) 18°—19°; at the moment of solution much higher numbers are obtained (Biration) e.g.  $(\alpha)_D = 85.86^\circ$ , after being five minutes dissolved.

It yields no levulinic acid on boiling with hydrochloric acid. Heated with sulphuric acid diluted with 3 vols. of water it yields furfuran; converted into furfuranide the yield of the latter is estimated as 25.5 per cent. The products of oxidation by nitric acid contain trihydroxyglutaric and trihydroxybutyric acids, but no mucic or saccharic acid. The osazone (m.p. 155°) has the formula  $C_{17}H_{26}N_4O_8$ . The molecular weight determined by Raoult's method is 151—156.—C. F. C.

*Researches on Wood Gum (Holzgummi).* H. J. Wheeler and B. Tollens. *Annalen*, 254, 320—333.

*Wood Gum from Beech Wood.*—The analyses of the authors gave numbers corresponding with the formula  $C_6H_{10}O_5$ , calculated with exclusion of the ash constituents (2.3 per

cent.). For the determination of rotation it was necessary to dissolve in a solution of sodium hydrate (2 per cent.), in which condition the number —69.62 was obtained, as the mean of 14 readings. By sulphuric acid hydrolysis (Stone and Tollens) and conversion of the furfuran into furfuranide 22.6 per cent. of the latter was obtained.

*Wood Gum from Fir Wood.*—The yield obtained was small, viz., 0.4 per cent. By hydrolysis, xylose was formed and identified after isolation.

*Wood Gum and Xylose from Jute.*—By treatment of the fibre-substance with 5 per cent. sodium hydrate solution, a derivate was obtained and isolated; the yield was 1.7 per cent., and the substance on combustion was found to contain C 42.9, H 6.3. To isolate xylose the original fibre was operated upon, and a yield of 6 per cent. of the pure substance obtained. This observation accords with the researches of Cross and Bevan (*J. Chem. Soc.*, 55, 200) in so far as they have shown that furfuran is obtained in quantity as a final product of hydrolysis of the fibre-substance; the source of which, the authors show, is probably the pentaglucose in question, the molecule of which is represented in the lignone complex.

Substances yielding pentaglucoses on hydrolysis may be generally recognised by means of the well-known reaction with phloroglucol and hydrochloric acid.

The brilliant red colouration is obtained with the following: (a.) which yield arabinose on hydrolysis:—Gum arabic, cherry gum, tragacanth, bran, quince mucilage, and the cellular tissue of the beet; (b.) which yield xylose:—Jute, wood gum (from beech and fir woods), fir woods, husks of cereals, &c. The reagent is best employed in the form of a saturated solution of the phenol in hydrochloric acid of 1.19 sp. gr. The absence of nitric acid must be ensured, as it determines a similar colouration of the reagent.

In conclusion the authors point out that wood gum is distinguished from the lignocelluloses by solubility in alkaline solutions in the cold, whereas they confirm the conclusions of Cross and Bevan (*loc. cit.*) in stating that the former are not resolved by simple hydrolysis.—C. F. C.

*On Compounds of Raffinose with Bases (Raffinosates).*

K. Beythien and B. Tollens. *Annalen*, 255, 195—213.

THE raffinose used was obtained from strontium molasses, by pressing the honey-like syrup, which contained a number of long needle-shaped crystals; recrystallising the solid mass from water, again pressing and dissolving the mass in 60—70 per cent. alcohol, treating with charcoal and crystallising. As the preparation, although in other respects satisfactory, yet reduced Fehling's solution slightly, it was redissolved in half its weight of water, a little slaked lime added, warmed until the reducing power disappeared, then mixed with three parts of 95 per cent. alcohol, treated with charcoal, and the small quantity of lime in solution precipitated by carbon dioxide. The raffinose crystallising from this solution was quite white, did not reduce Fehling's solution in the slightest, and 5 grms. of the dry substance in 50 cc. of water had at 20° C. an optical activity equivalent to  $(\alpha)_D = 104.4$ . The crystals had a composition corresponding to the formula  $C_{18}H_{32}O_{16} \cdot 5 H_2O$ . Before the authors took up the work only the sodium raffinosate was definitely known, although there were reasons for supposing that raffinose formed compounds similar to cane sugar with calcium and strontia, as raffinose is found in quantity in the liquid obtained when the strontium or calcium compound formed in purifying sugar molasses is decomposed by carbon dioxide.

They have prepared the following compounds:—

*Strontia-raffinosate.*—5 grms. of raffinose, 10 grms. of purified crystalline strontia, and 20 cc. of water are placed in a flask furnished with a reflux condenser, and heated 4—6 hours on a salt-water bath. The granular precipitate is then filtered hot by the suction pump and washed first with hot strontia water and then with alcohol, commencing with weak and ending with absolute, and lastly with ether. The white powder is exposed over sulphuric acid for some days, and has then a composition corresponding with the formula  $C_{18}H_{32}O_{16} \cdot 2 SrO, 11 H_2O$ . When the reaction takes

place in the presence of weak alcohol the same compound is formed. If the substance be heated up very slowly to  $80^{\circ}$  in a stream of dry air it loses its molecule of water and remains colourless, but if it be heated up too rapidly it becomes yellow, and it is then almost impossible to remove all the water. Whatever proportions of materials are used no other compound of this nature is formed. It cannot be easily prepared by proceeding exactly as in the preparation of the sucates. The theoretical quantity of raffinose is not obtained on decomposing this compound by carbon dioxide, so that some of it must be inverted or otherwise decomposed in this reaction.

**Baryta-raffinose.**—The attempt to prepare a baryta compound in the same way as the strontium compound was unsuccessful. On dissolving 3 grms. of crystallised baryta in 60 grms. water, and adding as much alcohol as possible without causing a precipitate, and then a solution of 2.5 grms. of raffinose in 5 grms. of water, a precipitate is thrown down which adheres to the side of the vessel, and on drying is found to have a composition corresponding to the formula  $C_{18}H_{32}O_{16}.BaO$ . If half as much again of baryta be employed a compound is obtained whose composition agrees fairly well with the formula  $C_{18}H_{32}O_{16}.2 BaO$ .

**Lime-raffinose.**—3 grms. raffinose, 100 cc. of water and 0.4 gm. of calcium hydrate digested at the ordinary temperature, filtered and heated for some hours on the water bath, gives a precipitate which after having been filtered by the suction pump, washed first with hot water and then with alcohol of gradually increasing strength, and lastly with ether and dried over sulphuric acid, possesses a composition corresponding to  $C_{18}H_{32}O_{16}.3 CaO, 2 H_2O$ . It loses its water when heated to  $100^{\circ}$  in a current of dry air.

**Lead Oxide-raffinose.**—A compound is obtained, having the formula  $C_{18}H_{32}O_{16}.3 PbO$ , either by adding a solution of lead acetate (25 cc. of a sp. gr. 1.232, to which as much ammonia as possible has been added without producing a precipitate) to a solution of raffinose (5 grms. in 20 cc. water); or by precipitating with alcohol a solution containing 3 grms. of raffinose in 10 cc. of water and 10 cc. of the solution of lead acetate, and drying the precipitate obtained in either way at  $100^{\circ}C$ . One of the authors pointed out previously (*Vereinzeitschrift*, 39, 748) that even dilute raffinose solutions are precipitated by ammoniacal lead acetate, but that the precipitation is not complete.

**Soda-raffinose.**—In a former examination of these compounds (*Ann.* 232, 182; this *Journal*, 1886, 243) Rischbieth and Tollens came to the conclusion that the formula of crystallised raffinose was  $C_{36}H_{64}O_{32}, 10 H_2O$ , but in consequence of the experiments of Tollens and Mayer (*Ber.* 21, 1566) and Brown and Morris (*J. Chem. Soc.* 1888, 610), with Raoult's freezing method and of De Vries' (*Compt. Rend.* 106, 751) on the diffusion coefficient of raffinose solutions, which all point to a formula  $C_{18}H_{32}O_{16}, 5 H_2O$ , the authors have considered a further examination to be necessary.

A strong aqueous solution of raffinose is added to sodium alcoholate contained in a mortar. On adding absolute alcohol a tough granular precipitate is formed which adheres to the mortar; the precipitate is purified by resolution in water and reprecipitation with alcohol and rubbed down first with absolute alcohol and then with ether. According to the amount of sodium used, the amount of the element in the resulting precipitates is either one, two, three, or four atoms to one molecule raffinose; the authors consider that two compounds only are formed, having respectively the formula  $C_{18}H_{31}O_{16}Na$  and  $C_{18}H_{31}O_{16}Na.OH$ .—A. L. S.

*On the Behaviour of Inverted Raffinose with Phenylhydrazine.* K. Beythien and B. Tollens. *Annalen*, 255, 214—216.

It has been observed that the inversion of raffinose, by heating with dilute sulphuric acid, occurs in two stages. In the first, the optical activity is almost halved; this occurs after a short heating. In the second, the optical activity falls to about  $20^{\circ}$ , and levulose, galactose, and dextrose are

produced; this is completed only after several hours' heating. One of the authors and others have already investigated the first stage of the inversion, and levulose has been isolated but not crystallised from the products.

The authors have sought to throw further light on this stage. They digested 10 grms. of raffinose, 90 cc. of water, and 9 cc. of hydrochloric acid (sp. gr. 1.19) for 10 minutes at  $68^{\circ}C$ ; after cooling, a slight excess of silver carbonate was added and the filtered solution made up to 200 cc. This was heated on the water-bath with 20 grms. of phenylhydrazine and 40 grms. of acetic acid. The yellow precipitate was filtered out and digested with acetone. The yellow mass remaining was recrystallised from alcohol, and was found to be identical with dextrosazone and levulosazone; but as it has already been observed that the glucose producing this is strongly levo-rotatory, it follows that this glucose is levulose. They agree with Scheibler (*Ber.* 22, 1678; this *Journal*, 1889, 718) in thinking that in partly inverted raffinose, besides levulose, there exists a compound of dextrose and galactose, as galactose will not crystallise out of these solutions. They have not obtained mannose-phenylhydrazine from this solution as Fischer (*Ber.* 22, 368; this *Journal*, 1889, 297) has indicated. The optical activity of the partly inverted solution was found to be  $50.9^{\circ}$  and 1 cc. of Fehling's solution was reduced by 0.0077 gm. of inverted raffinose.—A. L. S.

*Observations on the Melting Points of the Osazones and the Use of Phenylhydrazine.* K. Beythien and B. Tollens. *Annalen*, 255, 217—221.

In determining the melting points of the osazones, the authors find that it is very important that the temperature be raised quickly, and for the identification of an unknown osazone they recommend that the melting point be determined side by side with the osazone which it is supposed to be. They find, for instance, that the melting point of levulosazone varies from  $208^{\circ}$  to  $185^{\circ}$ , when the time of heating varies from 13—101 minutes. A point of importance in the preparation of the osazones is *not* to completely evaporate the mixture of hydrazine and sugar, as Löw has done in preparing the so-called formose derivative. On evaporating to dryness 15 grms. of phenylhydrazine hydrochloride, 22.5 grms. of sodium acetate, and 150 grms. of water on the water-bath, sodium chloride crystallised out and a reddish oil which crystallised on cooling was obtained. The salt was dissolved out with water, and the residue recrystallised from alcohol was found to be monoacetyl-phenylhydrazine, m.p.  $128.5^{\circ}$ . The authors think that this might be mistaken for an osazone. Tollens, in a note, states that phenylhydrazine produces nasty sores if allowed to get on the hand.—A. L. S.

*On the Formation of Lactic Acid by the Action of Bases on Raffinose and Cane Sugar. Raffinose not formed by the Action of Lime or Strontia on Cane Sugar.* K. Beythien, E. Pareus, and B. Tollens. *Annalen*, 255, 222—228.

THE observation (see page 310) that unless strontia-raffinose is dried very gradually it becomes yellow, led the authors to make the following experiments:—

Raffinose (40 grms.) and crystallised strontia (90 grms.) were boiled with water (1,000 grms.) for three days of eight hours each in a flask with reflux condenser. The raffinose at first precipitated gradually redissolved; the solution was filtered, and the strontia removed by the slightest excess of sulphuric acid. The filtered solution was shaken up with ether, the ethereal solution separated and evaporated, when 0.6 gm. of an acid syrup remained; this was diluted with water, boiled with zinc oxide, which it dissolved, and filtered. The filtrate gave crystals, which were found to be zinc lactate. Raffinose was recovered from the aqueous solution from which the ether was separated. Cane sugar treated in the same way yielded the same amount of lactic acid. Cane sugar treated similarly with its own weight of lime (as milk of lime) gave only 0.1 per cent. of lactic acid; when, however, the action was allowed to go on for double the time

(48 hours spread over 5—6 days) 1 per cent. of lactic acid was obtained.

It has been stated that raffinose is formed during sugar refining by the action of lime or strontia on cane sugar. The liquid obtained in the last-mentioned experiment (300 grms. of cane sugar and 300 grms. of lime with 6 litres of water, heated for 48 hours at the boiling point) freed from lactic acid was evaporated. Eight grms. of the syrup (containing 5 grms. of solid matter) were oxidised with 60 cc. of nitric acid (sp. gr. 1.15), the solution evaporated to one-third of its volume, and allowed to stand; not a trace of mucic acid crystallised out. As raffinose, when treated in this way, yields mucic acid, it is evident that no raffinose is formed by the action of lime on cane sugar. The same result was obtained when a similar experiment was made, using strontia instead of lime.—A. L. S.

*On Lactic Acid from Molasses.* K. Beythien, E. Pareus, and B. Tollens. *Annalen*, **255**, 228—229.

ALTHOUGH lactic acid, as shown in the previous abstract, must be formed in sugar refining, besides what may be produced by decomposition or fermentation of the beet-roots, yet no mention has been made of it in the literature of the subject. The authors have estimated the amount of lactic acid in a sample of molasses; 50—200 grms. of molasses from different sources were diluted with half their weight of water, made just acid with sulphuric acid and shaken up with ether. The ethereal solution, smelling of butyric acid, was evaporated on the water-bath with a little water until this smell disappeared, and then converted into the zinc salt; this was purified by precipitation from its solution with absolute alcohol, and, after treatment with charcoal, recrystallised. It was found to be zinc lactate, equivalent to 0.5 per cent. of lactic acid.—A. L. S.

*On Sorbite.* C. Vincent and Delachanal. *Compt. Rend.* **109**, 676—679.

SORBITE occurs in all fruits of the order *Rosaceæ*, such as pears, apples, medlars, cherries, plums, prunes, peaches, and apricots. Some of these are particularly rich in sorbite. From pears the authors have extracted 8 grms. of sorbite per kilo., and from eberries and prunes 7 grms. per kilo.

*Action of Hydriodic Acid upon Sorbite.*—When sorbite is acted upon by a large excess of hydriodic acid and distilled, a mixed product is obtained, consisting of hydriodic acid (and dissolved iodine) together with a dense liquid insoluble in water. This liquid is easily separated by decantation, and consists essentially of hexyl- $\beta$ -iodide,  $C_6H_{13}I$ , coloured brown by excess of iodine. 150 grms. of iodine are gradually added to 90 cc. of water and 35 grms. of red phosphorus contained in a half-litre retort, 60 grms. of crystallised sorbite are then introduced, and the whole gently heated, a current of carbon dioxide being passed through the apparatus. As soon as the reaction begins the heating is stopped; after it has finished the retort should be again heated, so as to distil over the last traces of iodide. The yield of iodide obtained is 63 grms. (theoretical yield = 66.6). The crude iodide, after washing and drying, boils at  $167^\circ$ , under a pressure of 753 mm. Heated with alcoholic potash, it saponifies readily, and on distillation the alcohol is obtained saturated with the hydrocarbon, which separates out on addition of water. The crude hydrocarbon, after fractional distillation, yields  $\beta$ -hexylene,  $C_6H_{12}$ , boiling at  $68.5^\circ$  (735 mm. pressure). The constitution of this is shown by the fact that, when oxidised with sulphuric acid and bichromate, it yields acetic and butyric acids.

The authors find that mannite, when treated with hydriodic acid, yields the same quantity of hexyl iodide; also that this, on treatment with alcoholic potash, yields the same products as in the case of sorbite, and in the same proportion.—D. E. J.

*On a New Sugar of the Aromatic Series.* Maquenne. *Compt. Rend.* **109**, 812—814.

THERE is an article known in commerce as "Pinite," which is a sugar derived from *Pinus lambertiana*. In its ready solubility in water, its slight solubility in alcohol, and its crystalline form it resembles the pinites of Berthelot. It is, however, more dextro-rotatory than pinites. It is proposed to call it  $\beta$ -pinites. Its formula lies between  $C_{12}H_{22}O_{11}$  and  $C_{12}H_{20}O_{10}$ , and it closely resembles sennite, with which it may be identical. It is readily attacked by warm hydriodic acid. The product so produced, when purified by precipitation from alcohol, is very soluble in water, almost insoluble in alcohol, and quite insoluble in ether. Its melting point is  $246^\circ C$ . It exactly corresponds in composition to the glucoses and its molecular weight, as determined by Raoult's method, is  $176^\circ$ — $178^\circ$ . It is an aromatic derivative, and is isomeric with inosite. The name  $\beta$ -inosite has been attached to it.—S. G. R.

*On  $\beta$ -Inosite.* Maquenne. *Compt. Rend.* **109**, 968—970.

THE author has shown (see previous abstract) that by heating pinites with an excess of hydriodic acid at  $120^\circ$ , methyl iodide is formed, together with a new sugar, named  $\beta$ -inosite by the author. Now this sugar is an isomer of ordinary inosite. Its chemical properties are the same as the latter. Thus a benzene additive compound may be prepared from it, which is a derivative of hexamethylene, so far as physical properties are concerned. It is distinguished by far greater solubility, higher melting point, by its crystalline form, and that of its ethers, which have no resemblance whatever to the corresponding compounds of  $\beta$ -inosite. Finally, the new sugar also turns the plane of polarised light to the right ( $\alpha_D = 65^\circ$ ). The latter property may be put down to a dissymmetrical constitution of  $\beta$ -inosite, which find expression in the fact that two hydroxides are joined to the same carbon atom.

Pinites is a mono-methyl derivative of  $\beta$ -inosite. Its composition is  $C_{12}H_{22}O_{11}$ , and it is therefore an isomer of bornesite and quebrachite, but differs both in composition and properties from quebrachite.—A. R.

*On Matézite and Matézo-dambose.* C. Combes. *Compt. Rend.* **110**, 46—47.

MATÉZITE is a sugar isolated by Girard (*Compt. Rend.* **76**, 995) from the juice of the caoutchouc of Madagascar, from which, by treatment with hydriodic acid, he obtained matézo-dambose, a sugar isomeric with the glucoses. Pinites, obtained from *Pinus lambertiana*, and called  $\beta$ -pinites (see two preceding abstracts) to distinguish it from Berthelot's pinites, gives on treatment with hydriodic acid a sugar isomeric with inosite, which is hence called  $\beta$ -inosite. By comparing their melting points and their rotatory power the author shows that matézite and  $\beta$ -pinites are the same body and that matézo-dambose and  $\beta$ -inosite are similarly one and the same thing.—S. G. R.

*Melitriose and Melibiose.* C. Scheibler and H. Mittelmeier. *Ber.* **22**, 3118—3124.

THE authors (this Journal, 1889, 718) have previously shown that the inversion of melitriose by means of dilute acids takes place in two stages, in the first of which levulose and melibiose are produced, the melibiose being subsequently split up into dextrose and galactose. In the present communication the authors prove the identity of melitriose, or raffinose, with Berthelot's melitose. This is contrary to the opinion held by Berthelot himself, that melitose is a compound of raffinose and eucalyn. The authors have prepared melitose from cotton-seed flour, according to Berthelot's directions, and find it to be identical in every respect with melitriose. They further find eucalyn to be identical with melibiose. Invertin acts upon melitriose in a similar manner to dilute acids. Melibiose and levulose are first formed, the melibiose being further converted by prolonged treatment with

than to a very partial refinement, in the mere ridding of these raw products of much of their molasses, without attempting any modification of the structure. It is the European refiner alone who develops pure sugar by eliminating all admixture of uncrystallised syrup, and thoroughly purifies it.

It is partly due to neglect in the selection of seed, and to its use in excess quantity in the North-West Provinces, that, whilst the yield of cane reaches, in Barbadoes and Upper Egypt, from 30 to 36 tons per acre, and in Demerara from 35 to 40, it does not ever in India attain even half such bulk. Apart from these causes, however, there are other radical defects, traceable in the exhaustion of the soil by too rapid a rotation of crops and neglect of open fallows; in the absence of the application of dry manures containing phosphates or mineral matters; in late and irregular planting; in careless surface sowing; in defective irrigation (the crop being submerged); and in the exclusion of air and light from the roots; whilst the crop is too often cut before maturity or too late (when the heat rapidly acidifies the juice). Nor is the expression of the cane comparatively more satisfactorily effected. In the West Indies, up to some 50 to 60 years ago the average of juice extracted represented, roughly, about half the weight of the cane pressed. With improved methods, from 70 to 85 per cent. is now attained, whilst India would appear still content with an average of 50 to 55. By the trituration of the ordinary native *kolhu* substances other than the juice, such as vegetable acids, are moreover pressed out in considerable quantities, owing to the breaking up of the fibres: it is probably due to this cause that European mills are finding such favour. Nor is the slovenly, careless method pursued of heating the juice less open to exception. Where sugar, even in solution, is subjected for too long a period to the action of excessive heat, such is its excessive sensitiveness that it becomes gradually changed into a mixture of dark substances, which are absolutely incapable of crystallisation. When separated finally from the sugar these unreduceable substances take the form of molasses or treacle. How much room for improvement there is yet in these provinces may be gathered from the fact that whilst the quantity thus lost is now reduced to a minimum of 2 per cent. in the West Indies, the loss on glucose in the North-West is still about 12 per cent., or 15 maunds of dry sugar, to 33½ of molasses. Whilst in the returns for the West Indies the weight of the dry sugar on each acre of production is three times as much as that of the molasses, the quantities are reversed in the East, and give twice as much molasses as dry sugar.

The courses in dealing with the juice here are two. It is either boiled to a dry consistency, which if clarified by alkalis is called *shakur*, or unclarified is known as *goor*; or it is boiled to a semi-liquid consistency as *rab*, when it is pressed in bags with the feet, developing uncrystallised syrup. The further treatment of this last is to strain it in crates to a substance which, when kneaded in the sun by trampling, becomes the *kacha chini* of internal commerce. The only further developments of semi-refined sugars in native hands are effected by boiling in milk and straining. The cane juice is allowed to fall unfiltered into earthen vessels accompanied by cane trash and dirt, whilst from this cause, and from the cutting of the cane into short lengths; through carelessness, exposure, and loss of time, it has often commenced actively to ferment before even being removed to the boiling pan. It has been found that the native raw sugars exported to Europe from India are generally of so miserable a quality as to prove valueless for refining purposes, and only to be capable of use by brewers. As to quantity, the amount of *rab* expressed per acre is in the North-West roughly about 4,500 lb., whilst of *goor* the result is less by about 500—a very low average. The average out-turn of dry sugar (Muscovado) in Barbadoes often exceeds 4 tons per acre. In Singapore and the Straits it is about 3 tons 4 cwt. undrained to 2½ dry. The vicinity of Calcutta gives about 1 ton 3 cwt.

## PATENT.

*Improvements in or relating to the Manufacture of Maltose or to the Fermentation of Amylaceous Matter.* W. P. Thompson, Liverpool. From "La Société Générale de Maltose," Brussels, Belgium. Eng. Pat. 5564, April 1, 1889. 6d.

In the saccharification of amylaceous matters by malt a minimum quantity of malt should convert into saccharine a considerable quantity of amylaceous matter. In practice this is not found to be the case, and a relatively large quantity of malt has to be used to arrive at even an imperfect degree of saccharification. This fact is explained by the development in the worts of harmful ferments which weaken the action of the diastase. The difficulty has been overcome by treating the malt with an antiseptic which will destroy the other ferments whilst having no injurious effect upon the diastase. For this purpose hydrofluoric acid is used, and by adding to 1 litre of infusion of malt containing about 200 to 300 grms. of malt, two or three drops of commercial hydrofluoric acid, it can be preserved for 8 or 10 days without losing any of its saccharifying power. For such an infusion the temperature of maximum saccharification is 25–30° C., and not 50–60°, which is usually employed.

In the alcoholic fermentation of yeast hydrofluoric acid has been found to exert a very beneficial action, preventing the development of other ferments and thus improving the yield of alcohol. It is also found that commercial hydrofluoric acid, in the proportion of 5 to 15 grms. per hectolitre of wort, can be employed as a simple preservative, and that the preservative action extends not only to the diastase, but to the yeast.—A. J. K.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*Acidity of Malt Liquors from a Medical Standpoint.*

H. L. Jones. Trans. Laboratory Club, 2, 72–76.

GOUT is produced by the deposition in the tissues of urate of sodium. This is due, not to the excessive production of uric acid by the gouty, but to imperfect elimination of it. The elimination of uric acid by the kidneys may be controlled by certain drugs, a dose of acid decreasing the excretion of urates, whilst alkalis have the contrary effect.

It is stated that certain alcoholic drinks, such as spirits and light wines, do not tend to produce gout, whereas others, such as port, beer, porter, &c., do have these evil effects. This is due, in the case of the heavy wines, to their acidity, coupled with their poorness in the alkaline salts of organic acids, which in the body would be oxidised to alkaline carbonates, and thus neutralise the effect produced by their acidity; whilst in the case of malt liquors, although, besides acidity, there are alkaline organic salts, these latter do not become alkaline carbonates when oxidised by the body, as there is sufficient phosphoric, sulphuric and hydrochloric acids to prevent this.—A. L. S.

*Some further Notes on the Application of the Polarimeter in Brewing.* J. Heron. Trans. Laboratory Club 2, 77–82.

THE determination of the specific rotatory power of the wort is recommended as giving valuable information regarding the relative amounts of maltose and dextrin present (this Journal, 1888, 259–276).

The author finds that the same malts mashed under similar conditions give worts having the same optical activity, and that when the mashing is conducted at a higher temperature the optical activity increases.

The following analyses are given comparing the composition of the beer after fermentation with the specific rotative power of the wort.

—	A <sub>1</sub>	A <sub>2</sub>	C <sub>1</sub>	C <sub>2</sub>	D <sub>1</sub>	D <sub>2</sub>
Matter fermented .....	58.9	53.7	68.9	68.3	63.6	58.9
Maltose unfermented .....	12.5	15.0	8.0	8.3	8.7	12.5
Dextrin .....	9.2	20.7	7.0	8.9	10.2	9.2
Undetermined .....	19.4	10.6	16.1	14.5	19.5	19.4
Polarisation of wort (α) <sub>D</sub> ..	108.3	122.7	103.5	105.0	118.4	119.0

A<sub>1</sub> and A<sub>2</sub> are different malts mashed under the same conditions; C<sub>1</sub> and C<sub>2</sub> are different malts, polarise the same and yield beer having similar compositions; D<sub>1</sub> and D<sub>2</sub> the same malts mashed at different times under similar conditions.

The wort for examination should be taken after it has been well boiled up in the copper, as it is found that samples taken at different periods whilst the wort is running into the copper have different optical activities. The wort should be collected free from hops, made to a gravity of 1.040 at 60° F., cleared with a few drops of finings, and after filtration the optical activity read off in the 200 mm. tube.

—A. L. S.

#### *The Use of Air in Malting.* H. Stopes. Trans. Laboratory Club, 2, 48—62.

In malting, as carried on in this country, little is done to modify or alter the quality of the air having access to the grain during the different stages of the operation, although the amount of moisture, temperature, &c., has a very important effect on the result. As an excess of moisture may be beneficial at one stage of the malting and noxious at another, and in the same way a temperature favourable for one stage may be unfavourable for another, and so on, so the use of air in malting must be considered separately at each stage.

**I. Storage of the Barley before Steeping.**—Before malting is commenced it is necessary that the barley should be sweated, that is the excess of moisture must be driven off the corn, in the course of which certain molecular changes take place in its constituents. It may either take place (1) normally in stack; (2) in bulk; (3) artificially on kiln. It is almost impossible to exercise any control over the sweating in stack, from self-evident reasons; in sweating in bulk the moisture is driven off too slowly and without proper access of air, and so the corn is likely to grow mouldy; sweating on kiln is an easily controlled process, as the amount and temperature of the air employed can be easily regulated and consequently the operation can be carried out with the greatest success.

**II. Steeping.**—Before steeping the malt may be with advantage graded and the dirt and dust removed by an air blast. The corn should not be allowed to absorb water before this stage as this would in some measure neutralise the value of the sweating. During the steeping the water dissolves a certain amount of albuminous matter, salts, sugars, &c. from the corn; it should be frequently changed so that these substances may be thoroughly removed, and between the successive steepings, the air should have free access to the corn.

**III. Couching and Growth on the Floor.**—At this stage the amount of turning, &c., depends on the temperature and amount of moisture in the air, and must be so arranged that while the air has free access to the growing corn, yet the corn is not deprived of too much of its moisture, which would stop its growth.

**IV. Withering.**—Here the air should have just the opposite effect, i.e., it should dry the grain. When this is not done with a proper quantity of pure and dry air there is much danger from mould.

**V. Drying.**—A proper control over the amount and temperature of the air is here of great importance; the air should be dry and of medium heat. If the temperature be not sufficiently high the resultant malt will be likely to produce unsound beer, and if the temperature be too high there may be excessive colouration, and in exceptional cases the diastatic power of the malt might be destroyed.—A. L. S.

#### *The Boiling of Wort.* C. F. Thatcher. Trans. Laboratory Club, 2, 83—92.

The boiling of wort with hops results in the precipitation of a certain amount of nitrogenous matter and in the extraction from the hops of substances having antiseptic properties, and others communicating a pleasant bitter taste to the beer, &c. In order that this may be done properly it is necessary that the boiling should be vigorous; the author gives a theory explaining this. He recommends that the copper be so set that the hot gases from the fire first impinge on the centre of the bottom of the copper and from there travel to its sides. He considers that the want of success which steam boiling has hitherto met with is not due to some inherent fault of the process, but rather to faulty plant; and recommends that the steam entrance to the jacket be below the centre of the bottom of the copper, that steam at not less than 50—60 lb. pressure be employed, and that proper arrangements be made to remove condensed steam so as to prevent its accumulation.

He, however, recommends fire boiling until it be conclusively proved that steam boiling has been used with practical success.—A. L. S.

#### *Some Points in Connexion with Practical Brewing.* E. C. Hansen. Trans. Laboratory Club, 2, 93—108.

**I.—On the Bacteriological Analysis of the Water and the Air for Brewing Purposes.**—The two processes which are in use for this purpose consist either in mixing a definite quantity of the water with liquid meat extract gelatin or with wort and beer, the culture media having been in the first instance sterilised, and forcing the infected solution. The author has made comparative experiments with these two methods, and finds that they yield very different results. For example, 1 cc. of an ordinary water gave in a series of cultures in beer, no vegetations, in a series of cultures of wort, an average of four vegetations, and in a series of Koch's gelatin, 100—1,500 vegetations; also that some organisms which are decidedly harmful to beer will not develop in meat extract gelatin unless infected with very vigorous cultures, such as for instance *Bacterium Pasteurianum* and various species of *Saccharomyces*. On the other hand it has been stated that some varieties of *sarcina* do not readily grow in sterilised wort whilst they do in nutritive gelatin. The author throws doubts on the harmful nature of these, as Petersen has observed a perfectly sound beer containing a number of these organisms.

He recommends that wort should in all cases be used as the culture medium, as organisms harmful to beer will not always grow in it after fermentation, and cannot agree with those chemists who make use of the gelatin culture method for the purpose of determining the worst of the water and air, but considers it, when viewed in the light of his experiments, as likely to yield to erroneous results.

**II.—Pure Yeast Culture and its Application in Top Fermentation Breweries.**—In his researches on bottom fermentation the author found that certain defects of beer, such as yeast turbidity, disagreeable flavours and smells, &c. were due to the presence amongst the yeast of certain varieties of yeast, and he was able to isolate and obtain in quantity a pure yeast which produced a beer having none of these disagreeable characters. This pure yeast has been largely adopted by low fermentation breweries, and is found to possess the following practical advantages: It prevents disease in the beer, and it gives a definite and precise result. It has been found that the high fermentation yeasts used in this country consist of several varieties of *saccharomyces*, and the author

considers that if these were isolated and examined that one of these varieties would be found to produce a beer of exceptional quality, and to be better in every way than the impure yeast now used. This is said to have been carried out with success by Joergensen, at Deventer in Holland, the fermentation being carried out at  $8^{\circ}$ — $12^{\circ}$  C. It was found at first that the pure yeast fermented more slowly, and that the attenuating power was weak, but by a little stronger aëration the difficulty was overcome. In the Australian Brewers' Journal (December 20, 1888, and January 20, 1889) an account is given of the successful application of this system, and it is there stated that no difficulty has been experienced in obtaining the after fermentation; on the other hand, Brown and Morris have informed the author that they have not been successful in isolating a pure yeast with which the impure pitching yeast could with advantage be replaced, and that beers fermented with pure yeast have been very slow and irregular in coming into condition. The author considers that in such a case it might be advantageous to use a second yeast especially for the after fermentation, but thinks that it will be found that such difficulties will not arise when a proper yeast is selected.—A. L. S.

*The Sterilisation of Wort in the Copper.* G. H. Morris.  
Trans. Laboratory Club, 3, 24—42.

THE author states that the present paper owes its existence to the adverse criticism which a statement he made in a former paper (Trans. Lab. Club, 2, 34) has met with. He assumes that the incredulity of those who have questioned the accuracy of this statement is based on the researches of Tyndall on the vitality of putrefactive organisms, and on the experiments on the resistive power of the spores of *Bacillus subtilis* and other organisms which have been made by Buchner, Brefeld, Fitz, Koch, and other investigators. The author considers that the criticisms in question show a total disregard of the conditions prevailing in the copper, and also an incomplete acquaintance with the researches mentioned above. He then shows that on *a priori* grounds we should expect the sterilisation in the copper to be complete.

Numberless germs, which were present on the malt, survive the temperature of the mashing process, and pass with the worts into the copper, where they are subjected to entirely different conditions. In considering these conditions the author examined the influence exerted by—

1. The temperature and duration of boiling.
2. The amount of acid present.
3. The amount of hops added.

In the first place, what are the conditions of temperature and duration of boiling? It is admitted that the temperature in the copper is higher than that of boiling water, but no determinations of the boiling point of wort have hitherto been published. A number of determinations, carefully made with an accurate maximum thermometer, gave temperatures varying from  $214^{\circ}$  to  $216^{\circ}$  F. The temperature naturally depends on the gravity of the wort, on the depth of the copper, and to some extent on the height of the barometer; but  $215^{\circ}$  F. may be considered to be a fair average temperature at the bottom of the copper. The average duration of boiling may be taken at two and half hours from the time at which ebullition commences.

The results of experiments on specific species of micro-organisms as regards temperature are then considered. It is known that the majority of vegetative cells are at once killed at a temperature of  $120^{\circ}$ — $140^{\circ}$  F., and of no species will the cells survive heating to  $212^{\circ}$  F. With endogenous spores the case is, however, different, and it has been abundantly proved that these will, under certain conditions, resist the prolonged action of a temperature of  $212^{\circ}$  F. Tyndall showed that *neutralised* hay-infusion could be boiled for many hours without effecting complete sterilisation, although acid hay infusions yielded much more readily. Brefeld also examined the resistive power of the spores of *Bacillus subtilis* in nutritive solutions; the spores of this organism are perhaps the most resistant of any known, yet it was found that they were still capable of germination

after 15 minutes at  $212^{\circ}$  F., after 60 minutes the number of spores which germinated was much diminished, whilst three hours at  $212^{\circ}$  F. sterilised the liquid. At temperatures higher than the boiling point the action was much more rapid—thus, 15 minutes at  $221^{\circ}$  F. was sufficient to kill all spores. Whilst Fitz found that the spores of *Bacillus butylicus* or *Bacillus amylobacter* could withstand a temperature of  $212^{\circ}$  F. for a time varying from 3 to 20 minutes, depending upon the nutritive solution in which they were heated.

The author considers on the ground of temperature and length of boiling alone there is good reason for assuming that all spores would be killed.

It is known that a wort from good sound malt contains a certain percentage of acid when it leaves the mash-tun, and this is increased when the hops are added to the copper. The following are some determinations of the amount of acid in unhopped and hopped wort:—

	Gravity.	Acid as Lactic Acid.
		Per Cent.
Wort from mash tun .....	1077.5	0.0724
Same wort (hopped) from the copper ...	1090.15	0.1317
Wort from mash tun .....	1078.6	0.0730
Same wort (hopped) from the copper ...	1093.1	0.1338
1st copper wort (hopped) .....	1093.05	0.1450
2nd copper wort (hopped) .....	1051.88	0.0991

With unsound and imperfectly grown malts the percentage would probably be higher. The known action of acid nutritive solutions is then examined in the light of the above determinations of acid in normal wort, and experiments of Pasteur and Tyndall with acid nutritive liquids are quoted to show that the amount of acid present in wort is sufficient to at once kill all spores at a temperature of  $212^{\circ}$  F.

Turning to the examination of the influence of hops, the author states that it is known that hops have a very strong antiseptic power, and the researches of Hayduck have shown that this property resides in one of the hop-resins; but nothing has been done with regard to the comparative value of hops as an aid to sterilisation by boiling. The amount of hops employed in the copper is a very variable amount, and it is almost impossible to give any definite figure on this point. In the experiments about to be described hops at the rate of 2 lb. to the barrel were employed.

The following experiments were carried out in order to prove the question experimentally. They were all conducted with the strictest regard to the requirements of bacteriological research. All vessels and solutions were sterilised in the usual manner, and all transference from vessel to vessel was carried out in such a way as to avoid aerial contamination. Unless otherwise stated, the flasks with the solutions were incubated for at least 21 days at  $80^{\circ}$  F., and a series of at least five flasks were employed for each observation.

*Experiment 1.*—Samples were taken in sterilised flasks, at different stages, of a brew of a light mild ale, with hops in the copper at the rate of 2.22 lb. per barrel, as follows:—

- A. Directly from the mash-tub taps, at a temperature of  $154^{\circ}$  F. (Grav. 1041.1.)
- B. Directly from the copper, 15—30 minutes after the wort broke through. (Grav. 1078.7.)
- C. Directly from the copper, after  $2\frac{1}{2}$ — $2\frac{3}{4}$  hours' boil, and immediately before the coppers were let go. (Grav. 1087.6.)
- D. After the worts had been on the coolers and refrigerators for some hours.

After incubation for 48 hours the samples were examined, with the following results:—

- A. Swarming with long bacilli and rod bacteria.\*
- B. No trace of organisms.
- C. No trace of organisms.
- D. Fermenting briskly, and the sediment showed *Sacch. apiculatus*, *Pastorinus*, and *ellipsoideus* forms, together with rod bacteria, constricted bacteria, and micrococci.

At the end of 10 days:—

- A. As before, the organisms sporulating freely.
- B. No trace of organisms.
- C. No trace of organisms.
- D. Still fermenting briskly, with various forms of yeast and bacteria. The liquid contained 2 per cent. of alcohol by volume.

At the end of 44 days:—

- B. } Still absolutely free from organisms.
- C. }
- D. Still fermenting slightly; 7.04 per cent. of alcohol present.

After 69 days:—

- B. } Still absolutely free from organisms.
- C. }
- D. Still fermenting slightly; 7.79 per cent. of alcohol present.

The experiment was interrupted at this point, and a small quantity of wort, fresh from the mash-tun, was added to each flask of B. and C.; in 48 hours all the flasks contained a large number of bacilli and bacteria.

This experiment shows, firstly, that the wort, as it left the mash-tun, contained a large number of organisms and spores capable of development; secondly, that 15 minutes' boiling in the copper was sufficient to arrest the growth of these organisms; and thirdly, that the wort, before entering the fermenting vessels, contained a vast number of germs capable of development in hopped wort.

That the worts from the coppers were really sterile—i.e., that the germs were actually destroyed, and not simply arrested for a time—was proved by the fact that the addition of a little wort containing germs which have survived the mashing process at once set up a vigorous bacterial growth.

Having regard to the high resistive power of malt-worts, and to the possibility of the germs being simply checked in development and not completely killed by boiling, the author carried out the following series of experiments, in which the resistive power was, on the one hand, reduced to a minimum by the addition of a large volume of sterilised water, and, on the other hand, the wort was largely diluted, and at the same time rendered very favourable to the growth of germs by the addition of sterilised hay-infusion.

*Experiment 2.*—Samples were taken directly from the copper of the first and second coppers of a light mild ale, brewed entirely from barley-malt, after two and a half hours' boil. The former had a gravity of 1086.0, whilst the latter weighed 1031.0, and neither copper was hopped at the rate of more than 2 lb. of hops to the barrel. Small quantities of each wort (at the rate of 1 in 10) were added to series of flasks containing—

- A. Sterilised hay infusion.
- B. Sterilised distilled water.

The latter were again divided into two sets, to each one of which a little of a pure culture of *Sacch. cerevisia* I., Hansen, was added. Seven series of flasks were thus obtained, containing—

- (1.) Hay infusion alone.
- (2.) 1st copper + hay infusion.
- (3.) 1st " + water.
- (4.) 1st " + water + *Sacch. cerevisia* I.
- (5.) 2nd " + hay infusion.
- (6.) 2nd " + water.
- (7.) 2nd " + water + *Sacch. cerevisia* I.

\* In this and the following experiments no definite species of organism are mentioned, but the fields are described in accordance with Pasteur's Plate I. The determination of species by mere microscopical examination is too problematical and uncertain to admit of the use of special names.

These were all forced for three weeks at a temperature of 80° F., and then carefully examined. It was found that in no case had the slightest development of bacteria taken place. The whole of the flasks were absolutely sterile, with, of course, the exception of those forming series 4 and 7, which contained a growth of pure yeast without the slightest admixture of other organisms.

In this experiment the wort was placed under conditions which would favour as much as possible the development of any latent organisms, and the results unmistakably proved that both the 1st and 2nd copper worts were completely sterilised when the samples were taken.

In order to anticipate the possible objection that the conditions prevailing at Burton are particularly favourable to complete sterilisation in the copper, and that different results would be obtained with inferior malts and other waters, samples of average malts from different parts of the country were taken and mashed with distilled water at 158° F. for two hours, in the proportion of 5 grms. of malt to 100 cc. of water. The wort was then filtered through sterilised filters into sterilised flasks, and samples of each mash forced at 80° F.:—

- (1.) Alone and as mashed;
- (2.) After 15 minutes' boil;
- (3.) After 15 minutes' boil with hops at the rate given above (2 lb. per barrel).

The samples were then submitted to microscopical examination, and the results obtained are given in the table at top of next page, which also includes, for comparison, the results obtained when some good and high-dried malts were examined in the same manner. The gravity of the worts varied from 1020 to 1025.

The only malt, the wort from which was not sterilised by 15 minutes' boiling, was that from Wolverhampton, and it was found that this was far the worst when forced before boiling. The wort obtained when the proportions of malt and water mentioned above are employed is of very low gravity, and consequently the acid present is also small, but even in this case the addition of hops brought about complete sterilisation.

The sterilising effect of the amount of acid in normal wort and of hops upon an easily putrescent liquid was then determined. For this purpose hay-infusion was selected, for Tyndall has shown with what difficulty the sterilisation of this liquid is attended. An infusion was prepared by steeping hay in water for some hours; the filtered liquid was divided among three series of flasks, one set of which was boiled for five minutes alone, to the second set lactic acid was added until the infusion contained 0.1 per cent. of acid, and to the third series hops were added at the rate of 2 lb. to the barrel. All the flasks were boiled for five minutes, and then forced at 80° F.

At the end of 48 hours, the liquid in all the flasks containing hay-infusion alone was turbid and swarming with organisms; all the others remained bright, and continued so for 23 days without developing a trace of bacterial or other growth. At the end of that time each flask was inoculated with a few drops of a fresh hay-infusion, with the result that in 48 hours every flask—both with acid and with hops—was swarming with organisms.

This experiment proves that either 0.1 per cent. of lactic acid or the small amount of hops employed is sufficient to sterilise, in five minutes' boiling, a liquid which in the ordinary course it is practically impossible to sterilise by simple boiling; whilst the latter part of the experiment shows that this amount of acid or hops does not prevent or sensibly retard the growth of germs added after boiling—a clear proof that the action in the first place is a true sterilising action, and not merely an arresting action of the growth of the organisms present.

As a further proof of the statement that all malts contain on their surface germs which survive the mashing process, a few examples were given, from among a large number of experiments, of the behaviour of mash-tun worts when

Malt.	Mashed at 158° F.		Mashed at 158° F., and the Filtered Mash afterwards Boiled for 15 Minutes alone.	Mashed at 158° F., and the Filtered Mash afterwards Boiled for 15 Minutes with Hops.	
	After 48 Hours' Forcing.	After 96 Hours' Forcing.			
London.....	Groups of bacilli with long leptothrix forms, and some short active bacteria.	Growth much developed.	No trace of growth after 21 days' forcing.	No trace of growth after 21 days forcing.	
Sheffield.....	Some short bacteria .....	Full of short, constricted bacteria, and some short rod bacteria.	Do. do.	Do. do.	
Wolverhampton .....	Thick film on surface of liquid, sediment showed bacilli, vibrios, medium and short rod bacteria, constricted bacteria and micrococci.	.....	After 7 days a few short bacteria could be detected.	Do. do.	
Hereford .....	Few short bacteria.....	Swarming with bacilli, short rod and constricted bacteria and micrococci.	No trace of growth after 21 days' forcing.	Do. do.	
Lincolnshire, No. I.....	Great many short, constricted bacteria, and some micrococci.	Growth much developed.	Do. do.	Do. do.	
Lincolnshire, No. II.....	Very great many medium and short rod bacteria and some bacilli.	Do. do.	Do. do.	Do. do.	
Burton (mild ale) .....	Trace only bacteria .....	Full of bacilli, short rod and constricted bacteria and micrococci.	Do. do.	Do. do.	
Burton, 1888 (dried at 215°).	Full of bacilli with leptothrix forms, rod and constricted bacteria.	.....	Do. do.	Do. do.	
Burton, 1889 (dried at 215° F.).	Few constricted bacteria.	Great many rod and constricted bacteria and some bacilli.	Do. do.	Do. do.	

forced at 80° F. The samples were all collected directly from the mash-tun in sterilised flasks, and the results well illustrate the universal distribution of germs on malt:—

Malt.	Barrels per Quarter.	Microscopical Examination after 48 Hours.
Pale ale malt .....	2·32	Full of bacilli, short bacteria and micrococci.
	2·26	Swarming with bacilli, leptothrix forms, and rod bacteria.
Mild ale malt.....	2·30	Swarming with bacilli, rod bacteria, and some chaplets.
	2·25	Full of long bacilli and rod bacteria.
High-dried malt (215° F.)	1·85	Swarming with long bacilli, rod bacteria and some micrococci.

Turning to the source of the bacterial and other contamination of beer, if the sterilisation in the copper is so complete, the author mentions several sources of post-copper contamination. In experiment 1, all the samples marked D—that is, those collected as the wort was running from the refrigerator to the fermenting vessels—quickly started into fermentation and developed yeast and bacteria. There are two possible sources of this contamination—namely, from the plant or from the air. The first of these was in this case quite out of the question, and therefore it is necessary to fall back upon the second source.

The author states that he has invariably found that when suitable nutritive media are used, a very large number of organisms is always found in the air of all breweries. This is the case in all localities in the brewery, but naturally the chief source of danger is whilst the wort is on the coolers, and in breweries where the old-fashioned, large, open coolers are used, the contamination at this point is enormous. He then gives the results obtained in two

breweries, designated A and B, in which different systems are adopted, and where the differences are very marked.

In A the cooler is a comparatively deep vessel, with an area of only 70 square yards; in fact, it may be almost more correctly termed a settling-back than a cooler. The last portions of the wort leave this vessel at a temperature of 125°–130° F., running from thence over the refrigerators into the fermenting vessels.

In B the large shallow coolers are employed; these have an area of 426 square yards, and the wort is cooled to the air temperature long before the last portions are off the coolers.

Analyses of the air on both these coolers were made with about the same result as far as regards the number of organisms falling on the square inch; but it is obvious that this number is of less importance in the case of A, with the smaller area and the comparatively high temperature, than it is in the case of B, with the large area and the favourable temperature. Thus, in B, a calculation gave 60,860,000 as the number of organisms falling per hour on the coolers, and if this is multiplied by 4·5, the number of hours the worts are on the coolers, an enormous number is obtained for the total possible contamination at this stage. The author does not for a moment suggest that this number of organisms survive and develop in the wort and pass into the beer, but he has been able to carry this matter a step further, and estimate the number of organisms capable of development in the worts which have passed over the respective coolers. Samples were taken, in sterilised flasks, from the two breweries, when only a few barrels remained up on the coolers, and a measured volume of each wort was mixed with—

(1.) 5 per cent. sterilised gelatin;

(2.) 5 per cent. meat-extract gelatin;

and after three days' culture, the number of colonies developed in each case was determined. From this number the following figures were obtained by calculation:—

A brewery:—

163,548,000 colonies per barrel developed in gelatin alone.

16,354,800 colonies per barrel developed in meat-extract gelatin.

B brewery :—

1,406,512,800 colonies per barrel developed in gelatin alone.

14,065,128,000 to 21,097,692,000 colonies per barrel developed in meat-extract gelatin.

With the gelatin alone, the majority of the colonies consisted of *Saccharomyces* and *Torula*, with many bacteria and moulds. The numbers are simply enormous, but when compared with the number of cells of yeast added at barming, the number is small, and forms but a small percentage of the total cells present, the average number of yeast-cells present per barrel, immediately after pitching, closely approximating to 724,800,000,000 for each pound of barm used.

The author emphasises the great difference there is between the figures for A and B breweries, corresponding to what would be expected from the different systems in vogue in the respective breweries. At both breweries, he says, cleanliness is most rigidly observed in every detail, and the whole contamination must be derived from the air.

Morris considers that in the above there is the germ of a bacteriological test of real value, for the number of colonies obtained will afford some idea of what may be termed the *initial contamination* of the wort, which will depend upon the cleanliness of plant and the purity of the air, which will, again, be dependent upon the state of the brewing premises, the vicinity of "disease-spots" to the coolers, and so on. He states his belief that systematic examination of the worts as they run into the fermenting vessels would be productive of much useful information, and suggests the following simple method for carrying out the determination :—

"Take some wide-mouthed bottles with a capacity of about 12 oz. and with a mouth of about 1½ in. diameter. Plug the mouth with sterilised cotton-wool, and sterilise the whole by heating for 2—3 hours at 150° C. Collect a sample of the wort in a sterilised flask, and add a small measured volume, varying from 0.1 to 0.5 cc., according to the contamination of the wort, to each of a series of the wide-mouth sterilised bottles; a little liquefied and sterile 5 per cent. gelatine is then added, and well mixed with the wort. The mixture is spread over the sides of the bottle, and allowed to solidify evenly. After incubation for a few days the colonies develop, and can then be counted, and, if necessary, removed for examination by means of a bent glass rod."

This method is simple, and has the advantage of telling how many organisms are present in the wort capable of developing in wort. In fact, it gives the *initial contamination* of the wort, and also serves as an index to the state of the plant and atmosphere.

From the foregoing experiments the following three main conclusions are drawn :—

1. That the wort as it leaves the mash-tun always contains germs capable of development; this is the case even with sound, high-dried malt.
2. That these worts are completely sterilised in the copper, and in a much shorter time than it is usual to boil them.
3. That myriads of air-borne organisms are sown in the wort whilst on the coolers, and these can be determined in the wort before it enters the working-squares.—G. H. M.

*Studies on Diastase.* C. J. Lüntner and F. Eckhardt. J. prakt. Chem. 41, 91—96. (See this Journal, 1887, 296, and 1890, 91.)

THE authors treat in the first place of the diastatic ferment of ungerminated barley (and correspondingly of wheat) and question whether it is identical with malt diastase. If this last were so, then they should furnish similar temperature curves in converting a given quantity of starch.

Experiments conducted similarly with soluble starch, however, showed that malt diastase acted best at 50°, but well at 55°, and strongly at 62°; while the most favourable temperature for extract of barley was 45°, although it acted at 50°. This explains why the iodine reaction is longer in

disappearing in the case of barley extract and starch at 50° than in the case of malt diastase, it being the more favourable temperature for the last named.

The authors conclude by commenting on Reyehler's so-called artificial diastase. This name should be reserved for malt diastase with which it is now identified, and not confused by being used for other ferments.—D. A. S.

## PATENTS.

*Improvements in Processes for Rectifying and Distilling Alcohol, and in Apparatus therefor.* E. A. Barbet, Agde, France. Eng. Pat. 4549, March 15, 1889. 8d.

IN an ordinary rectifying plant, consisting of a boiler, a column with trays, a condenser or analyser, and a refrigerator or cooler, the patentee has found that between the liquid which flows back from the analyser on to the trays and the liquid from the refrigerator there is little if any difference, and that the back-flow from the analyser is four or five times greater than the flow from the refrigerator, so that the analyser continually returns a large quantity of the volatile products back into the column. Also that the liquid on the trays is much freer from the volatile impurities than the back-flow, this liquid being at the end of a two hours' flow of as good a quality as the liquid from the refrigerator after eight or ten hours. In order to carry these improvements into effect, he introduces a small supplementary refrigerator and passes through it the liquid from one of the upper trays of the column. Communication between the tray and refrigerator is controlled by a stop-cock. This is closed at the commencement of the distillation until the liquid on the tray is sufficiently pure; to determine this a small testing cock is inserted on the connecting tube. The liquid is tested occasionally during the distillation until the end products begin to appear, when communication with the tray is cut off. During the whole operation the ordinary refrigerator condensing the vapours from the analyser is in operation as usual.

The inventor makes use of a similar device, towards the end of the distillation, to prevent the accumulation of fusel oil in the boiler, having a pipe and stop-cock communicating with one of the lower trays of the column and running liquid off from it as soon as fusel oil accumulates there. Drawings of the apparatus accompany the specification.—A. L. S.

*Improvements in and connected with the Purification of Raw Spirit in order to produce Highly Rectified Spirits of Wine, and Apparatus therefor.* C. Schmitt, Wiesbaden, Germany. Eng. Pat. 5647, April 2, 1889. 8d.

ALTHOUGH petroleum spirit of low boiling point cannot extract fusel oil from alcohol, yet when potassium carbonate solution is first mixed with the alcohol, and the strengths arranged so that the formation of two layers is avoided, then under certain conditions petroleum spirit will extract the whole of the fusel oil. The inventor has made experiments in order to determine the best proportions of the materials, the most successful one being as follows :—300 cc. of a 30 per cent. spirit containing 0.2 per cent. of fusel oil was mixed with 110 cc. of a solution of potassium carbonate (sp. gr. 1.5) and shaken up with 600 cc. of petroleum spirit. On standing the petroleum ether rose to the top and was found to contain the whole of the fusel oil. On a commercial scale the solutions are mixed in the proportions as indicated above in a suitable vessel supplied with stirring gear, the liquid allowed to settle, and the petroleum run off and passed in a finely-divided state first through cold water, (which absorbs all the ethyl alcohol taken up by the petroleum, but very little of the fusel oil), then through water at 50°—60° C., in which all the fusel oil is extracted, and lastly through 50—60 per cent. alcohol, which absorbs all the aromatic bodies, and the purified petroleum is ready to be used over again.

The lower liquid from the mixing vessel consists of the purified alcohol, water and potassium carbonate. The addition of more solid carbonate causes it to separate into two layers; the lower one contains very little alcohol, and

on concentration is ready for use again; the upper layer consists of 94 per cent. ethyl alcohol containing a little carbonate; this latter may be removed by adding either sulphuric acid or gypsum, when the potassium sulphate formed, being insoluble in alcohol, is precipitated. The clear solution consists of almost pure strong ethyl alcohol. A drawing accompanies the specification.—A. L. S.

*Improvements in Yeast-Cakes.* H. H. Lake, London. From J. Barnes, New York, U.S.A. Eng. Pat. 17,523, November 4, 1889. 6d.

A YEAST-CAKE is prepared by subjecting a mixture of yeast and prepared corn meal to great pressure in a mould having a rounded form with no sharp angles. The effect of the pressure is to force the finer granules of corn meal to the surface and thus form a protective coating. A further protective coating is produced by dipping the cake in a solution of cane sugar and drying. A drawing accompanies the specification.—A. L. S.

*Improved Process for Treating Beer and making it keep permanently in Good Condition.* J. F. H. Grouwald and E. H. C. Ochlmann, Berlin, Germany. Eng. Pat. 19,376, December 3, 1889. 4d.

THE inventors propose to avoid the difficulties of the pasteurising process by distilling the beer; the beer residue is then fined and remixed with the distilled liquid. It is afterwards aerated with carbonic acid gas and bottled or filled into barrels.—A. L. S.

*A New Method of Killing Microbe-like Minute Living Organisms, such as Yeast Cells, Bacilli, and the like, contained in Wines, Alcoholic and other similar Liquors.* W. Spilker, Berlin, Germany, H. Bendel, San Francisco, U.S.A., M. Hahn and C. Löwe, Berlin, Germany. Eng. Pat. 19,996, December 12, 1889. 4d.

THE inventors claim that by circulating wine and other similar alcoholic liquids in tubes in an electric or magnetic field, and in the direction of the lines of force from one pole to another, all living organisms are killed, and that the alcoholic liquor is matured in the same way as by lengthened storage. In the case of spirits a maturing effect is produced equal to that resulting from several years' storage.

For treating 1,000 litres of wine, a current energy of about 7,000 volt ampere hours has generally been used; that is to say, in 12 hours about one cubic metre of wine would be treated by 1 horse-power.—A. L. S.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

### (A).—CHEMISTRY OF FOOD.

#### PATENTS.

*A New or Improved Mode and Means of Estimating the Acidity in Milk, Cream, Whey, and Curd in the Process of making Butter or Cheese.* J. Gray, Stranraer, and T. Clement, jun., Pollokshields. Eng. Pat. 4,966, March 21, 1889. 8d.

A CYLINDRICAL glass vessel, provided with graduated scale, and containing the milk with a little phenolphthalein or other chemical indicator, is connected with a bottle containing solution of an alkali. The alkali is gradually run in, during agitation (the connection from the alkali bottle being at the bottom of the milk cylinder), until change of colour denotes that the acid has been neutralised. The quantity of alkali added is ascertained by reading the scale before

and after the experiment, and from this the acidity is calculated. On the graduated scale, at different levels of acidity, markings may be made, naming the stages at which the "rennet" may be added and other operations performed.—T. L. B.

*Improvements in the Making of Butter for the Purpose of Preserving the same.* F. McIntyre, Glasgow. Eng. Pat. 5052, March 23, 1889. 6d.

THE presence of germ life during the whole process of making butter is prevented. In the first place, any germs which may be contained in the milk are destroyed by the application of heat. The churn is so fitted that no germs whatever can enter, and before use it is steamed. An operating box, for washing and packing the butter, is fitted with arm-holes, provided with folds or pucks, so that entrance of germs is prevented during the operation. All the apparatus is steamed before use, and the salt is heated, either in the solid state or in aqueous solution. Water used for washing is likewise previously boiled. Instead of having separate air-filtering tubes on separator, churn, and room in which the butter is worked and packed, one room may be used enclosing the whole, the air entering the room being drawn through a tortuous pipe, part of which is kept at a red heat.—T. L. B.

*Improvements relating to the Preservation of Shell-fish.* A. A. Freeman, Philadelphia, U.S.A. Eng. Pat. 14,670, September 17, 1889. 6d.

UNDER ordinary conditions oysters and other shell-fish, after being kept some time, open their shells and the juices escape; the fish thereby loses its flavour, and in a short time becomes unfit for use. To prevent such opening of the shells the patentee binds them round with wire while fresh.—T. L. B.

*A New or Improved Method for Sweetening Margarine, Butter, and other Oils and Fats.* P. Heinz, Frankfurt-on-the-Main, Germany. Eng. Pat. 19,158, November 28, 1889. 4d.

SACCHARINE is dissolved in the fat; the amount dissolved, and therefore the resulting sweetness, depending on the temperature to which the fat is raised during the process of solution.—W. L. C.

### (B).—SANITARY CHEMISTRY.

#### PATENTS.

*Improvements in Water Purifying Apparatus.* H. Carrol, South Croydon. Eng. Pat. 9569, June 8, 1889. 8d.

THE purification of the water is effected in a lower vessel, having side receptacles for deposit, formed by inclined curved plates, which extend upward to near the underside of a baffle-plate extending across the vessel so as to leave a space at each side above the receptacles, and between the plate and sides of the lower vessel. Above this vessel are two tanks, one for receiving the reagent from a tank above, and the other for the water to be purified. The reagent and water flow down a pipe into the lower vessel, and rising upwards pass between the tops of the receptacles and underside and edges of the baffle-plate and the sides of the lower vessel, and upwards (through a filtering medium, if desired) to the outlet pipe. There are two sheets of drawings and three claims.—E. S.

*New or Improved Means or Apparatus for Softening and Filtering Water or other Liquids under Pressure.* "The Water Softening Company, Limited," E. Easton, Westminster, and H. Carrol, South Croydon. Eng. Pat. 12,973, August 16, 1889. 8d.

A CLOSED vessel, preferably of a conical form, and having its smaller end downwards, contains the lime or other reagent. This vessel stands upon a second, into which the

water or liquid to be treated is admitted under pressure. This stands upon a third vessel, the lower part of which is separated from the upper part by a perforated plate on which is placed filtering material, covered by another plate. The water or liquid under pressure enters the second vessel and the lower end of the conical vessel at the same time, and after mixing with the reagent flows out by a pipe at the top which joins the main supply pipe, the mixed liquid together entering the second vessel from which it overflows through a pipe to the bottom of the third vessel, and after passing through the filtering materials flows out for use or storage. The conical vessel is supplied with the reagent through a funnel regulated by a valve.—E. S.

## XIX.—PAPER, PASTEBOARD, Etc.

*The Process of Engine-sizing.* E. Muth. *Dingl. Polyt. J.* 275, 29–40 and 71–80.

This paper deals with the rosin-sizing process as usually practised, giving a careful survey of the principles underlying it, with deductions therefrom in the form of such practical details as are calculated to lead to the best results. In the beating process the object should be to draw rather than cut the fibres, with the result of securing the maximum of felting with interspaces of minimum size. The alternative method produces a web parting very rapidly with its water on the machine, with proportionate loss of the suspended particles of sizing compounds. These particles are held by a fine well-felted web as in a filter, and the final closing of the interspaces with and by the sizing matters is effected by the pressure of the couch-roll, to the weight of which special attention must be paid. In the preparation of the resin-soap the object should be to secure in the final product the maximum proportion of emulso-resin (Milchharz) i.e., uncombined resin, dissolved, in the soda-resin compound. For this the maximum temperature of the "boil" should be 70°, and the water a minimum. (So much importance is attached by some manufacturers to this constituent of the sizing mixture that the presence of a sufficient quantity is ensured by the solution of an additional proportion in the finished resin-soap.) The completion of the boiling is recognised by dipping a spatula from time to time. On drawing out, the cooling mass should break short off without forming long threads. The time of boiling, with a charge of 6 cwt., should not exceed four hours. The complete separation of the resin-soap requires from 2–3 days' standing. The colouring matters of the rosin are for the most part retained in solution. For their complete removal, with the lye residue, the mass may be treated with successive quantities of salt solution. The quantities of rosin, soda (Solvay) and water are variously formulated by different authorities. The author's table comprises numbers within the following limits: rosin, 100; soda, 18–27; water, 65–2,000. The calculated quantity of carbonate for complete conversion into the soda compound is 17 per cent.; using 18.5 per cent. soda the author found 15 per cent. of emulso-resin in the product. These proportions may be considered normal. In re-dissolving the compound for use, the optimum of dilution is variously stated at 25–70 parts of water to 1 part of total resin.

The effective sizing of the web requires first the absorption of the materials by the individual fibres, and secondly the filling of the interspaces which are, of course, of variable dimensions. The necessary gradations of fineness of the precipitated matters, emulso-resin and resin-alumina compounds—are perhaps sufficiently secured by the usual mode of adding the sizing solution and the aluminium sulphate. Greater efficiency may be attained by adjusting the conditions in view of these requirements. It is also recommended to take into account, in using hard waters, the objection to the precipitation of lime and magnesia compounds of the resin-acids, since by decomposition in the paper the effects of imperfect sizing may be produced.

This difficulty is easily met by treating the water to be used in the beater with a calculated quantity of aluminium sulphate. The utility of using gelatin in the engine-sizing process is very questionable, the amount retained by the paper being necessarily small. The albuminates, on the other hand, are highly recommended, being precipitated by alumina salts in a form especially favourable to the effectual distribution of the albumen, and to the qualities of the paper made with this addition, more particularly in point of elasticity and surface. It is recommended to add the aluminate (ammonium) in concentrated solution (30–40 per cent.) at the beginning of the beating. In regard to the completion of the process on the machine the author directs special attention to the shaking (felting), and the temperature of the drying cylinders, more especially the first, in order that the resin and resin compounds may be brought into the right condition of fusion, ensuring a homogeneous compacting of fibre and sizing materials.

A process involving fine adjustment of so many factors, chemical and mechanical, cannot be laid down on hard and fast lines universally applicable, but requires special study for every set of circumstances, i.e., for each mill. As an illustration of extreme variations between efficient and inefficient consumption of sizing materials, the author cites two cases from his experience, in one of which the percentage of resin used was  $2\frac{1}{2}$ , in the other 8 per cent. on the paper. Adding to these numbers the same weights of alumina salt necessary for precipitation, the difference of consumption of material in the two cases is seen to be very great.

In the summary of points which concludes the article the author emphasises the three more important conditions of efficient sizing, viz.:—

- (1.) The composition of the pulp (fibre) and its condition when beaten.
- (2.) The physical properties of the precipitated resin-alumina mixture.
- (3.) The communication to the web of a satisfactorily high temperature on the drying cylinders.—C. F. C.

*Imitation Japanese Paper.* W. Herzberg. *Mitt. k. techn. Versuchs. Anstalt, Berlin*, 1889, 152–153.

THE author gives the results of an investigation of a paper recently introduced in obvious imitation of the genuine Tokyo paper, offered at one-fourth the price, 1.45 M. per kilo., and stated to be of a quality fitting it for such uses as for official documents, share coupons, &c. The following are the results of mechanical tests: *Breaking lengths* (a) 7.24 k.m., (b) 4.50; mean 5.87. *Elasticity* (extension per cent.), (a) 1.6, (b) 5.1; mean 3.4. Sheets of the paper were exposed freely to the air and light (hung in a window) for three months and again tested. A diminution of 9 per cent. in breaking length and 41.2 per cent. in elasticity was noted. This result is noteworthy, the more so as the paper consisted of a pure wood cellulose, apparently sulphite cellulose. It contained only 3 per cent. of ash constituents, and was engine-sized (rosin and starch). The author promises further tests of the paper after intervals of exposure.—C. F. C.

## PATENTS.

*A New or Improved Wood Felt suitable for Surgical Bandages and other Purposes, and a Process for Producing the same.* G. Walcher, Stuttgart, Germany. Eng. Pat. 16,546, November 14, 1888. 4d.

THE wood fibres are ground up into a paste with spirit or other volatile liquid. The spirit is drawn off, the felt dried by heat, and then compressed between rollers to render it pliant.—E. J. B.

*Improved Method of and Means for Protecting Apparatus used in the Manufacture of Sulphite Cellulose.* J. F. Salomon, Berlin, and H. Brünger, Liegnitz, Germany. Eng. Pat. 18,003, December 10, 1888. 8d.

THIS process relates to the formation on the insides of boilers of a crust or scale which will resist the action of the acid solutions (bisulphites) used in preparing wood pulp. The scale is formed by heating the boiler, preferably by means of hot air passed into an outer casing, while it is filled with a saturated solution of calcium sulphate.

—E. J. B.

*Improvements in Treating Vegetable and Animal Fibre and Textile Fabrics whereby the same are Bleached, Strengthened, Prepared for Dyeing, and Improved in Appearance and otherwise.* M. Ziegler, London. Eng. Pat. 84, January 2, 1889. 6d.

THE fibre is cleansed by soaking it in a "diluted solution of sulphuric acid neutralised by ammonia." Gelatin is dissolved in dilute sulphuric acid, to the solution glycerin and ammonia are added. To this is added oleic acid previously saponified by bicarbonate of potash. The fibre is boiled in this solution for several hours and dried. When dry it is treated in a solution made by boiling oxide of zinc with permanganate of potash. When thoroughly combined, bisulphite of soda is added, then a small quantity of neutral gum or shellac. The fibre is finally treated with dilute sulphuric acid, washed and dried.—E. J. B.

*Improvements in the Manufacture of Parchment Fabric.* L. D. Dobler, Paris, France. Eng. Pat. 1767, January 31, 1889. 4d.

ANY suitable fabric is covered with a layer of paper or other similar material. It may be applied to one or both sides, and is caused to adhere by a size which is insoluble in water such as that described in Eng. Pat. 9949, of 1887 (this Journal, 1886, 516).—E. J. B.

*Improvements in Apparatus for the Manufacture of Paper.* D. M. Watson, Glasgow, and T. T. M. Lumsden, Edinburgh. Eng. Pat. 2439, February 12, 1889. 6d.

THE improvement consists in a new form of "Deckle-shifting" apparatus, whereby the width of the web of paper can be altered at will. Descriptive drawings accompany the specification.—E. J. B.

*An Improved Paper.* G. Newbery, London. Eng. Pat. 4310, March 12, 1889. 4d.

PAPER is coated with a mixture of 9 lb. of moist pipe-clay, 2 oz. of tallow, 14 lb. of size, 1½ lb. of black-lead, or ¾ lb. of oxide of manganese. Such paper, when slightly pressed with a hard point, is marked as with lead pencil.

—E. J. B.

*Improvements in the Preparation of Wood Pulp for the Manufacture of Paper, Cloth, Cordage, or any other Textile Fabric.* F. J. Cheesbrough, Liverpool. From H. and W. Pataky, Berlin, Germany. Eng. Pat. 9694, June 12, 1889. 4d.

GREEN wood is crushed between rollers, and at the same time subjected to the action of a stream of water whereby a number of soluble matters are removed, and the subsequent treatment with alkali simplified, a considerable saving being effected. A small quantity of sulphite of soda may be added.—E. J. B.

*A New or Improved Composition for Treating Paper and similar Material to render Writings or other Markings Indelible thereon.* D. C. Simpson, Edinburgh. Eng. Pat. 16,342, October 17, 1889. 4d.

PAPER is treated with a solution made by dissolving 1 lb. of lead acetate, ¼ lb. of potassium chlorate, and 1 oz. of copper acetate, in 1 gallon of water.—E. J. B.

*Improvements in Edge Runners or Mills for Reducing Paper-making Materials or other Substances.* A. E. Ried, Sideup. From A. Abadie, Angoulême, France. Eng. Pat. 18,674, November 21, 1889. 6d.

THE improvement consists in making the bed of small pieces of iron, preferably of a rectangular shape, interspaced with a softer material, such as lead or wood, the surface of the latter being slightly lower than that of the former. In this way the runners are prevented from slipping and the material is more rapidly reduced. There is also an arrangement for raising or lowering the scrapers.—E. J. B.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Orexine (Phenyldihydroquinazoline).* Pharm. J. 20, 709—710.

THIS is one of a series of compounds recently synthetically prepared by Paul and Busch (Ber. 22, 2683). It is described as a derivative of quinazoline, a body represented by a structural formula differing from that of quinoline in having two CH groups of a naphthalene ring replaced by N instead of one. In dihydroquinazoline there is an imido-group the hydrogen of which is replaceable by an alkyl group, and it is that compound in which the substitution is effected by a phenyl group that is now put forwards under the name "orexine."

THIS compound is manufactured by heating the sodium compound of formanilide with the corresponding quantity of *o*-nitrobenzylchloride, and after the purification of the resulting *o*-nitrobenzyl formanilide, reducing it to phenyl-dihydroquinazoline by means of zinc dust and acetic acid. The hydrochloride of this base is produced in needles containing two equivalents of water of crystallisation, gradually given off in an exsiccator the crystals becoming efflorescent. The melting point of the hydrated crystals is 80°, that of the anhydrous, 221° C. When laid upon the tongue the compound tastes slightly bitter and leaves an intense burning sensation; it also powerfully irritates the mucous membrane of the nose. In ether it is insoluble, but it is readily soluble in hot water and in alcohol, and for this reason the hydrochloride is preferable in dispensing than the free base, which is almost insoluble in water. From an aqueous solution of the hydrochloride the base is separated by alkalis as an oily precipitate which eventually crystallises. Orexine hydrochloride is a substance which induces appetite and stimulates digestion. It is neither an antipyretic nor an analgesic.

In the case of healthy persons the appetite is stated to increase immediately after the first dose, but with most patients the improvement is only manifested after some days.

The formula recommended for administration is 2 grms. of orexine hydrochloride made up with extract of gentian

and althaea powder into 20 pills gelatin-coated, three to five of which are to be taken once or twice daily with a large glass-full of meat broth, a considerable quantity of liquid being required on account of the pungent properties of the compound.

*The Solubility of Quinine and Caffeine.* Pharm. J. 20, 710—711.

ANTIPYRINE increases the solubility of quinine (Pharm. J. 19, 861). It is now stated that it exercises a similar influence on caffeine. Crinon reports that it suffices to add to caffeine a slightly superior weight of antipyrine to render it soluble in the cold, and that if heat be employed 50 centigrams of caffeine may be made to dissolve in 10 cc. of water if 75 centigrams be added, the solution remaining clear on cooling.

*Report on New Drugs and Fine Chemicals.* Merck's Bull. 3, 1890, 1—8.

THE MYDRIATIC ALKALOIDS OF THE SOLANACEÆ—*cont.* (This Journal, 1890, 212.)

*Homatropine* (Hydroxytoluyltropine),  $C_{16}H_{21}NO_3$ —Ladenburg, in the course of his researches on the synthetic production of alkaloids, obtained a series of artificial alkaloids by the action of hydrochloric acid on certain salts of tropine, itself a fractional derivative of atropine. To the group of alkaloids thus obtained he applied the generic term "Tropines." Thus, by the action of hydrochloric acid amongst other products, the following were obtained:—

From tropine tropate—

*Atropine*, in every respect identical with the natural alkaloid.

From tropine salicylate—

*Salicyl-tropine*, a weak poison, devoid of action on the pupil.

From tropine phthalate—

*Phthalo-tropine*.

From tropine mandelate—

*Homatropine*,  $C_{16}H_{21}NO_3$ , *Hydroxytoluyltropine*.

Of all the foregoing, the last named is by far the most interesting, its peculiar action on the eye rendering it of therapeutic value. Experience proves in fact that it will be very serviceable in ophthalmology.

*Homatropine* dilates the pupil just as strongly as atropine does, but it possesses less of the paralysing effect of that mydriatic, and what is of the greatest importance, the recovery from the *mydriasis* is far more rapid than when atropine has been used (Völkers and Goetz, Inaug. Dissert. Kiel, 1880). Atropine dilations, even with very weak solutions, continue for several days up to a week, whereas a homatropine dilation commences to diminish after a few hours' duration, and in the course of 24 hours, as a rule, every trace of it will have disappeared. Moreover, homatropine, unlike atropine, is a very weak poison, and does not, as atropine often does, superinduce cutaneous eruptions. It is likely to be very useful in examinations of the *Fundus oculi*, &c., since it permits of the eye being used again within a very brief period.

*Homatropine* in the pure state forms clear and regular crystals, the form of which has never yet been determined. Its salts with hydrochloric, hydrobromic, and sulphuric acid, are white, and crystallise well.

*Homatropine hydrobromide*.—This salt forms white, crystalline plates, and is soluble in 10 parts of water. The solution is quite permanent and the salt is not hygroscopic. The more recent physiological experiments were principally made with this salt (Schweinitz and Hare, Amer. Med. News, 1887, Dec. 731; Jackson, Amer. Med. News, July 1888). After instillations of large doses of homatropine, its bitter taste becomes perceptible, but not the dryness of the pharynx which follows the use of atropine.

*Aconitine*.—Notoriously the various brands of aconitine in the market exhibit very marked differences in the strength of physiological action, and the observance and expression

of some rigorous distinction between the different grades has become a matter of serious importance. Dr. Van Reuterghem (*Neederl. Tijdschr. voor Geneesk.* 1889, 9) has to this end subjected several aconitines of various origin to a series of precise therapeutic tests, the experiments being made upon his own person.

In order to realise certain definite primary symptoms he had to employ certain amounts of the different brands experimented with. These quantities constituted what he termed the "sufficient dose." The effect indicated was found to be caused by—

From 0.25 to 0.5 mgrm. ( $\frac{1}{250}$ th to  $\frac{1}{125}$ th grain) of the two crystallised aconitines of Merck or Duquesnel.

From 10 to 15 mgrms. ( $\frac{1}{10}$  to  $\frac{1}{6}$  grain) of the amorphous aconitines of Merck and Chantenaud.

From 200 to 300 mgrms. (3 to  $4\frac{1}{2}$  grains) of Friedländer's aconitine.

This shows a range of comparative degrees of potency from 1,200 down to 1, i.e., a similar effect is secured from the strongest preparation by a dose only  $\frac{1}{1200}$ th to  $\frac{1}{800}$ th the size of those required of the weakest preparation tested under the name of "Aconitine."

*Jambul* is a powder or fluid extract of the seed or bark of the *Syzygium jambolatum*, a tall tree growing in the American and Asiatic tropics, and belonging to the *Eugeniaceæ*, a branch of the *Myrtaceæ*. It is a specific in cases of *Diabetes mellitus*. That *Jambul* has a retarding action on the diastatic fermentation of starch was first observed by Lascelles Scott. W. Elborne and W. H. Morse succeeded in procuring a reduction of the diuresis and of the sugar in the urine by administering small quantities of the powdered fruit. Gräser, of Bonn (Centralblatt f. klin. Med. 1889, No. 28), has confirmed the preceding by the use of *Jambul* extract, and he has moreover proved that the drug is harmless in the animal economy.

*Researches on Narcotine.* W. Roser. *Annalen*, 254, 334—368.

A RÉSUMÉ of researches bearing on the constitution of cotarnine and narcotine. A closely-reasoned account of the evidence, as regards the former, afforded by these, is summed up in the annexed constitutional formula:—

*Narcotine* containing the residues of hydrocotarnine and opianic acid is formulated therefore as subjoined:—

It is closely related to another opium alkaloid, viz., papaverine, both being derivatives of a benzyloquinoline.

—C. F. C.

*Denaturing Alcohol by Means of Wood Spirit and Pyridine.* A. W. Hofmann, G. Krämer, and L. Loewenherz. Chem. Ind. 12, 521—525.

THIS article treats of the present aspects of the method of denaturing alcohol, after two years' experience of its employment in the German Empire. The complaints at first raised against the use of pyridinised spirit for domestic purposes have now nearly ceased, especially since the quantity to be added has been reduced from 1 per cent. to 0.5 per cent. of pyridine. In a few cases, such as those in which varnish or polishes are manipulated in confined or badly ventilated places, it may still be advisable to allow the spirit to be treated with 5 per cent. of wood spirit only, whilst the method of denaturing at present in force throughout the Empire consists in the addition of 2 per cent. of wood spirit and 0.5 per cent. of pyridine to the alcohol. The greatest difficulty experienced during the introduction of the new method arose in the increased prices of pyridine consequent on the sudden demand for large quantities, but the impetus thus given to its manufacture and import from other countries, especially from England, has eventually brought down the price below that existing before the introduction of the measure, and the values of wood spirit have fluctuated in a similar way, but to a lesser extent. Thus the values adopted by the Commission on Denaturing were 300 M. for pyridine and 120 M. for wood spirit (per 100 kilos.), but these rose to 400 M. and 140 M. respectively, whilst at the present time the prices are under 90 M. in each case, and the mixture itself may now be bought for 80 M. per 100 kilos. In numerous factories, where the use of alcohol with wood spirit was adhered to, the pyridinised alcohol has at length been adopted, its use being found preferable as being free from the control exacted by the excise officials when wood spirit only is the denaturing agent. The following table shows the favour extended by consumers to the pyridine as against the wood spirit method:—

	Quantities of Pure Alcohol denatured.	
	With the Official Mixture.	With 5 per Cent. Wood Spirit.
	HL.	HL.
October to December 1887 .....	37,257	13,785
January to March 1888 .....	28,146	7,847
April to June 1888 .....	31,928	7,681
July to September 1888 .....	37,342	5,241

Pyridinised alcohol, as used in households, gives out no smell while burning in a lamp, but, on blowing out the flame, an unpleasant smell is experienced, which is, however, less disagreeable than the smell of a recently-extinguished petroleum flame, to which consumers generally have easily become accustomed. Alleged harmful results from inhaling the vapour of pyridinised alcohol have been shown to be groundless. In order to cover the objectionable smell of the pyridine, it has been permitted, in some cases, to add a certain quantity of lavender or rosemary oil. Brief reference is made to other substances which have been proposed for the purpose of denaturing alcohol. Amber oil, caoutchouc oil and camphor oil, as well as naphthalene and oil of turpentine, are inadmissible, as they are readily removed by dilution with water and treatment with animal charcoal. Shellac does not render the spirit sufficiently undrinkable, whilst mercaptan or bone oil are much more objectionable than pyridine. The use of wood spirit would not effect the desired purpose in less proportion than 10 per cent., and the quantity then required would be too far in excess of the possible production, and even then the excise would not be fully protected, as experience in England has shown. Experiments made with suitable petroleum fractions showed that it could be removed by dilution with water and treatment with charcoal. Bitter substances are open to the same objection, and they

interfere with the proper burning of the spirit. An additional objection to the use of wood spirit is that acetone and allyl compounds, which are its most important denaturing constituents, prevent its application in many technical industries. On the whole there seems to be no more suitable substances for denaturing alcohol than those which have been selected, the same method having been adopted in Austro-Hungary and Switzerland; at the same time the authors hold the view that a more satisfactory solution of the difficult problem may yet be found. They advocate the establishment of a central institution to which all questions respecting denaturing and other excise matters could be referred, such as exists in England.—G. H. B.

*Synthesis of Aconitic Acid from Acetylenedicarboxylic Acid.* J. M. Lovén. Ber. 22, 3053—3056.

IN preparing acetylenedicarboxylic acid from dibromosuccinic acid and alcoholic potash, the author obtained two acids, viz., oxalic and aconitic acid. This is explained by the presence of an excess of alkali, which, reacting upon the acetylenedicarboxylic acid decomposes it into the two acids above mentioned.

The author supposes that the acetylenedicarboxylic acid takes up the elements of water to form oxalacetic acid, which condenses with a molecule of unchanged acetylenedicarboxylic acid which then decomposes with potash.

—J. B. C.

*Belladonnine.* E. Dürkopff. Ber. 22, 3183—3184.

TO obtain belladonnine free from hydrocarbons, hyoscyne, tropine, &c., the crude material is digested in acid solution with ether and chloroform to dissolve out hydrocarbons. The atropine is converted into tropine and tropic acid, whilst hyoscyne dissolves, and the belladonnine remains unaltered, the dissolved hyoscyne is isolated as gold double salt. The occurrence of hyoscyne in crude belladonnine explains the presence of pseudotropine in its decomposition products. From the latter a base was isolated by Ladenburg and Roth, and also Merling, which, however, they were unable to identify with pseudotropine, but which according to the author is identical.—J. B. C.

*Researches on Crystallised Digitalin.* Arnand. Compt. Rend. 109, 679—681.

THE author finds that tanghinin, one of the active principles of the Madagascar tanghin (this Journal, 1889, 1008) is very similar in its properties to crystallised digitalin. Both substances are non-nitrogenous, both are practically insoluble in water, but are soluble in all proportions in chloroform, and equally soluble in moderately concentrated warm alcohol. They do not belong to the class of glucosides, for they do not yield glucose or any other form of sugar when treated with boiling dilute acids; under such treatment they simply resinify. They are also similar in their physiological behaviour; both are violent cardiac poisons, and both occur in nature in conjunction with true glucosides which have a powerful action upon the organism.

It has been stated by Schmiedeberg that digitalin prepared according to Nativelle's process is a mixture of several crystalline substances. The author contradicts this assertion, and the object of his communication is to establish the fact that digitalin so prepared is a perfectly definite chemical product. The material first used in his experiments was prepared in the author's laboratory by Nativelle's process from 20 kilos. of Vosges digitalis, purified by washing with cold alcohol. The pure digitalin forms thin brilliant white flakes melting at 243°. 100 grms. of absolute alcohol at 14° dissolve 0.650 grm. Contrary to Schmiedeberg's assertion, it is soluble in boiling benzene. The method of examination adopted was that of "fractional solution" by successive washings with absolute alcohol at 14°. The solubility was not found to vary, nor was there any sensible variation in the melting points of the residues,

or of the successive fractions when determined after evaporation and crystallisation. Similar results were obtained with a sample of digitalin prepared and furnished by Adrian.—D. E. J.

*Digitalin and Tanghinin.* Arnaud. *Compt. Rend.* **109**, 701—703.

By the action of baryta on digitalin in presence of water in a sealed tube heated to 180° for several hours, a crystalline body is formed insoluble in water and containing barium in combination. The compound after purification melts at 305°—310°. The analysis of this compound leads to the formula  $C_{31}H_{50}O_{10}$ . The action of baryta appears to be one of hydrolysis, as the original digitalin cannot be reproduced by eliminating the barium from the compound.

It may be formulated as follows:—

The action of baryta on tanghinin is similar; but an amorphous barium compound is formed and it is probable that two molecules of water are taken up:—

—J. B. C.

*Comparative Activity of Different Digitalins.* G. Bardet. *Compt. Rend.* **109**, 755—756.

CRYSTALLISED digitalin and amorphous digitalin prepared according to the formulae of the French Pharmacopœia are completely soluble in chloroform, they have identical activity and are always comparable in their effects. The German digitoxin is not completely soluble and its effect is two to three times weaker in the different preparations used, than the official digitalin. The French digitalin and the German digitalin are both soluble in water and insoluble in chloroform, though they are not definite products. They are similar in action; but their activity is 20 to 35 times less than that of the digitalin of the Pharmacopœia or that which is soluble in chloroform.—J. B. C.

*Action of Related Chemical Compounds on Animals.* Woleott Gibbs and H. A. Hare. *Amer. Chem. J.* **11**, 435—448.

THE authors desire to ascertain whether general laws exist by which the action of chemical compounds on the system may be predicted. They have set themselves to examine, therefore, and compare the actions of compounds related to each other, such as, for instance, nitrobenzene and the nitrotoluenes, ortho-, meta-, and para-compounds, the nitrophenols, hydrazines. Thus far they have obtained the following results from experiments made on dogs:—

*O-, m-, and p-nitrophenol.*—Of *o*-nitrophenol 0.1 gm. to each kilo. in the weight of the dog produces death; of *m*-nitrophenol slightly less than this suffices; of the para-compound 0.01 gm. per kilo. only is needed to kill. The substances were rapidly injected into the jugular vein. The toxicity is thus in the following order: para, most poisonous, then meta, and least poisonous the ortho compound. They all produce death by paralysing the heart, and not by a respiratory action. On bodily heat they seem to have very little effect, although their true antipyretic value is not certainly determined.

*O-, m-, and p-nitraniline* all slow the pulse. Of the ortho-compound a dose of 0.3 gm. per kilo. of the animal produces death when injected into the jugular vein; methaemoglobin is produced in the blood. When given by the stomach violent sneezing comes on and lasts for about 40 minutes. The meta-compound shows all the symptoms of aniline poisoning. Para-nitraniline is the most poisonous member of the group, 0.04 gm. per kilo. of animal producing death when injected into the jugular vein.

*Amido-benzoic acids* are without effect on the system, whether given by the stomach or intravenously.

*Nitro-benzoic acids* are likewise without effect.—T. L. B.

*Indian Grass Oils.* F. D. Dodge. *Amer. Chem. J.* **11**, 456—469.

THERE are found in commerce at least five volatile oils which appear to be obtained from various tropical grasses of the genus *Andropogon*. They are: oils of citronella, lemon grass, Indian or Turkish geranium, ginger grass, and vetiver. The author has made a detailed examination of citronella oil. Three samples of the oil were obtained; two of these were found to have been adulterated with kerosene, and were therefore discarded; on the remaining sample the work of this communication was performed. The oil was of a light greenish-yellow colour; its density at 16° was 0.8770, at 26° 5', 0.8750; on distillation, all, with the exception of about 10 per cent. of thick oily residue, passed over between 200° and 240°. A saturated solution of sodium bisulphite gives a solid mass when shaken with the oil, phenylhydrazine combines with it with evolution of heat, and it reduces ammoniacal silver solution. In order to isolate the aldehyde, the bisulphite compound was made, filtered, pressed, washed with ether, and air-dried. The dry mass was then mixed with crystallised sodium carbonate, and distilled with steam. The steam-distilled aldehyde, after drying several days over calcium chloride, forms a colourless oil of not unpleasant odour and sharp acid taste. Its specific gravity at 25° was found to be 0.8509; it boils at 202°—207°, leaving a resinous residue. Results of analysis agreed well with the formula  $C_{10}H_{18}O$ , so that the aldehyde is isomeric with borneol and geraniol. The author terms it citronellaldehyde. It is dextro-rotatory; a column two decimetres long produces a deviation of about 7° for sodium light. With bromine it forms a dibromide, which is decomposed on heating to 120°, and on reduction it gives the alcohol boiling at 225°—230°. Ordinary oxidising agents appear to split up the molecule, giving a mixture of acids. By the action of phosphorus pentoxide on the aldehyde, a terpene boiling at 175° is obtained. Discussion of the constitution of the aldehyde is naturally premature.

As regards the other oils, Gladstone noted that oil of lemon grass resembled citronella oil very closely, but no extensive work has been published on the subject. Flückiger has remarked that it behaves with bisulphite solution exactly as citronella oil does. Oil of Turkish geranium has been examined by Jacobsen (*Ann.* **157**, 232), who found it to contain a monatomic alcohol, geraniol,  $C_{10}H_{18}O$ . Oil of ginger grass has not been investigated, and oil of vetiver, which appears to be different from all the other grass oils, is somewhat inconvenient to work on by reason of its costliness.—T. L. B.

## PATENTS.

*A New or Improved Manufacture of Para-Amido-Phenol Ethers.* B. Willecox, London. From "The Farbenfabriken vormals Fr. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 1771, January 31, 1889. 6d.

PHENETIDINE (*p*-amidophenol ether) is diazotised and combined with phenol. This azo compound is converted into the ether which is subsequently reduced with iron and hydrochloric acid, yielding two molecules of phenetidine. The methyl or amyl ethers may also be used. The following are the quantities employed: 50 kilos. of *p*-amidophenol ether hydrochloride are diazotised and combined with 32 kilos. of phenol in an alkaline solution. 30 kilos. of the yellow dyestuff formed—*p*-phenol-ether-azo-phenol—are converted into the ethyl derivative by dissolving them in 300 litres of alcohol, adding 6.5 kilos. of caustic alkali and 15 kilos. of chloride or bromide of ethyl and heating in an autoclave to 100° C. The alcohol is then distilled off and the alkylised derivative, insoluble in soda lye, is separated from any non-alkylised colouring matter. In order to reduce the ether 30 kilos. of it are added to 120 litres of water and 70 kilos. of hydrochloric acid of 20° B., and 20 kilos. of iron filings are slowly added. When the reduction is complete lime is added to the solution, and the phenetidine distilled over with steam. By heating the *p*-amido-phenol ethers with dry sodium acetate and acetic acid they are converted into the mono-acetyl derivatives, which are employed as drugs. The acetyl derivative of *p*-amido-phenol-ethyl ether is phenacetine.—T. A. L.

*Improvements in Fixing Perfumes.* A. Domeier, London. Eng. Pat. 3745, March 2, 1889. 4d.

THE patentee adds about 4 per cent. of glycerol to such common perfumes as consist of odorous substances dissolved in alcohol (e.g. Eau-de-Cologne) and claims that it aids in retaining odour which is apt to be carried off by the evaporation of the alcohol.—B. B.

*An Improved Toilet and Nursery Powder.* H. W. Langbeek, Loughton. Eng. Pat. 4643, March 16, 1889. 4d.

PURIFIED wool fat or lanolin is warmed and mixed with an absorbent such as carbonate of lime, gypsum, fuller's earth, or kaolin; the product, which may contain as much as 20 per cent. of wool fat without losing its powdery appearance, is mixed with one to four parts of starch powder, alone or together with wheat flour, perfumed, and is then claimed as an improved toilet powder. Antiseptics such as carbolic, salicylic, or boric acid, iodoform, or mercuric chloride, may be added if desired. Hard specimens of wool fat may be softened previous to mixing by the addition of 10–30 per cent. of vaselin or lard.—B. B.

*An Improved Process of Recovering Volatile Solvents retained in Substances treated therewith.* H. H. Lake, London. From "La Société Anonyme des Parfums Naturels de Cannes," Paris, France. Eng. Pat. 10,280, June 24, 1889. 6d.

THE process consists in recovering the solvent from the spent material in the liquid state without volatilising it (unless it be a very small part), and so obviating all the expenses necessitated by the successive vaporisation and condensation. A small jet of steam is introduced into the extractor above the material instead of below, as in the ordinary method, and gradually forces the solvent downwards, expelling it in the liquid state through the lower part of the extractor into a reservoir. The steam having slowly passed through the entire material, escapes through the bottom of the extractor, being mixed with the last traces of the solvent, which may be collected by passing it through a refrigerator before entering the reservoir.—E. S.

*An Improved Method or Process of and Apparatus for the Lixivation of Various Materials.* H. H. Lake, London. From "La Société Anonyme des Parfums Naturels de Cannes," Paris, France. Eng. Pat. 10,361, June 25, 1889. 8d.

THIS invention is designed to combine the rapidity of action of that class of apparatus characterised by rapid circulation with the safety of a second class characterised by slow circulation. The improvement is "based upon the employment of two series of conjugated vessels which are all together alternately filled and emptied of the liquid used in treatment." For the mode by which this is effected, the drawing attached to the specification must be consulted. There are three claims.—E. S.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*Smokeless Explosives.* Sir F. Abel. Royal Institution Lecture, January 31, 1890.

THE lecturer said that the introduction of machine and quick-firing guns had shown the great desirability of using a smokeless powder, and caused chemists to experiment with substances which would yield no solid products on combustion. "Amide powder," so called from the volatile potassium amide, which was believed to be formed from the mixture of potassium and ammonium nitrates contained in

it, gives very good results, the smoke rapidly clearing away, but it deteriorates after long storage at high temperatures as in the magazines of ships.

THE next important improvement was the powder produced by the French for their Lebel rifle. It is now known that it differs chiefly from other smokeless powders in containing picric acid. Attention was also called to the attempts made to use gun-cotton, which at first were not uniformly successful. The basis of the modern smokeless powders consists of different varieties of gun-cotton, and the lecturer referred to Schultze and E.C. powders, and then showed how gun-cotton could be dissolved in ether or acetone and dried in homogeneous films, which could be cut into shreds or the jelly could be passed through dies and the solid produced in any desired form. Nobel found that nitroglycerin dissolves or gelatinises gun-cotton, and he has in this way produced a very good powder entirely unaffected by water. Some camphor is incorporated with it to render it less sensitive to shocks, but the volatility of this ingredient is a drawback to the powder. It was pointed out that the very perfection of this powder caused new difficulties, for there being no solids deposited in the bore of the gun, the friction of metal on metal was found to be very great. The lecturer, however, was confident that these difficulties would be overcome, and had no doubt as to the ultimate adoption of smokeless powders for military and naval purposes.—W. M.

*Some Notes on Modern High Explosives.* Eng. and Min. Jour. 48, 567–568.

THE explosives referred to are arranged in five classes—(1) gun-cotton class, (2) the pierates, (3) the chlorate compounds, (4) the nitroglycerin preparations, and (5) the pancastites. In America the use of explosives of the first class is practically confined to military and naval purposes, and the only picric acid preparation known to be on the American market is Emmensite (this Journal, 1888, 868).

THE chlorate class is represented by rackarock, which consists of potassium chlorate put up in cartridge bags of cotton cloth, immersed for a few seconds before use in nitrobenzene or "dead oil."

UNDER the fourth division, the large number of nitroglycerin preparations is very remarkable. The nitroglycerin is used in the form of ordinary dynamite or with an explosive absorbent under the name of giant powder, and consisting in some instances of 40 parts nitroglycerin, 48 parts sodium nitrate, and 12 parts sawdust.

JUDSON powder is another preparation largely used and contains from 5–20 per cent. of nitroglycerin absorbed by an explosive base, which has approximately the following composition: sodium nitrate, 70 parts; sulphur, 15 parts; resin, 3 parts; asphalt, 2 parts; and anthracite coal, 10 parts.

ATLAS powder consists of nitroglycerin, wood fibre, magnesium carbonate, and sodium nitrate in varying proportions.

HERECULES powder in its strongest variety contains magnesium carbonate, 20·85 parts; potassium nitrate, 2·10 parts; potassium chlorate, 1·05 parts; white sugar, 1 part; and nitroglycerin, 75 parts. The "Miners' Friend Dynamite," manufactured by the Hecla Powder Company, is said to be very safe. Foreite is the most typical example of the gelatin-dynamite class, and consists of nitroglycerin partially gelatinised with soluble gun-cotton and then absorbed by an explosive base.

UNDER the fifth head are described, Roburite, Securite, Bellite and Romite, which have been already noticed in this Journal (1888, 589).—W. M.

## PATENTS.

*An Improved Smokeless Safety Gunpowder.* C. F. Hengst, Plumstead. Eng. Pat. 13,656, September 21, 1888; Amended December 21, 1889. 6d.

IN this amended specification (compare this Journal, 1889, 478) the only alteration in the text consists in the deletion of the following sentence: "I do not, however, confine myself to potassium permanganate as an oxidising agent, as

I find in practice I may employ with equal advantage any convenient oxidising substance to effect the desired object." In the fourth claim for the words "The utilisation of the dust or refuse, &c." are substituted "The utilisation in the manner described of the dust or refuse, &c." In the fifth, for "The various processes and materials" are substituted "The combination of the various processes and materials."

—O. H.

*An Improved Mode of Preparing Explosive Compounds for Use.* A. V. Newton, London. From A. Nobel, Paris, France. Eng. Pat. 1888, February 4, 1889. 6d.

THE object of this invention is to prevent nitrate of ammonia and other hygroscopic powders from absorbing moisture by enclosing the charges in explosive water-tight bags or cases. The bags or cases are composed of thin sheets of collodion or soft celluloid, the joints being secured by applying a suitable volatile solvent such as acetone or acetic ether.

The material, composed of nitroglycerin and nitrocellulose, as described in Eng. Pats. 1471 of 1888 and 4479 and 9361 of 1889 (this Journal, 1889, 214), is, however, more suitable for making the explosive bags. This material rolled into sheets can easily be made into bags or cases by heating to 80° C, the parts to be joined and pressing the surfaces together, or volatile solvents may be used, as in the case of collodion.—W. M.

*Improvements in the Manufacture of Explosive Compounds.* H. S. Maxim, Crayford. Eng. Pat. 4477, March 14, 1889. 6d.

By the addition of oil, "preferably castor oil," to compounds of dissolved gun-cotton and nitroglycerin, nitrocelatin, or the like, the inventor is enabled to produce an explosive which burns slowly and acts efficiently in rifles, can be cut or pressed into suitable forms, and does not deteriorate when exposed to atmospheric influences.

Suitable proportions are from 2—5 per cent. of castor oil, 10—16 per cent. of nitroglycerin or the like, and the remainder gun-cotton.—W. M.

*Improvements in Explosives and in the Method of Manufacturing the same.* P. de Montravel, London. From O. Mavaut, Herentals, Belgium. Eng. Pat. 5031, March 22, 1889. 6d.

THE object of this invention is to produce a cheap explosive which shall be more powerful than ordinary gunpowder. For this purpose one of the numerous nitrated hydrocarbon derivatives, such as dinitrobenzene, is added to the three substances composing gunpowder. The explosive thus produced can be exploded without a detonator. After mixing the four substances together, they are heated to 140°, when the dinitrobenzene and sulphur melt and cover the other ingredients with a film, which on cooling prevents the moisture from acting on the explosive.—W. M.

*Improvements in the Manufacture of Explosive Compounds.* E. Liebert, Berlin, Germany. Eng. Pat. 5503, March 30, 1889. 4d.

THIS invention consists in the addition of 3—5 per cent. of iso-amyl nitrate to nitroglycerin; or an emulsion of glycerin and iso-amyl nitrate or iso-amyl alcohol may be nitrated. It is claimed that nitroglycerin thus prepared does not freeze at 35° below zero, is less sensitive to blows and shocks than pure nitroglycerin, and also that the explosive force is greater than that of pure nitroglycerin.—W. M.

*An Improved Process of Producing Ammonium Nitrate.* A. W. and J. A. Wahlenberg, Stockholm, Sweden. Eng. Pat. 12,451, August 6, 1889. 4d.

See under VII., page 293.

## XXIII.—ANALYTICAL CHEMISTRY.

*Pyrometry.* H. Le Châtelier. Soc. tech. de l'Ind. du Gaz.

THE author first enters upon a preliminary discussion of temperature, and the general principles of measurement of temperature as illustrated by the mercury thermometer, the hydrogen or air thermometer, and Wedgwood's pyrometer. He states that the hydrogen thermometer (which is most nearly correct) and the nitrogen and the mercury thermometers are related to one another in the following way:—

Hydrogen Thermometer.	Nitrogen Thermometer.	Mercury Thermometer.
0	0	0
50°	50°01	50°10
100°	100°00	100°00
150°	149°86	149°75
300°	300°15	298°79

The best known temperatures at the present time are:—ice melting point, 0° C.; water boiling point, 100° C.; naphthalene boiling point, 218° C.; then, with possible errors of 2°, we have mercury boiling point, 360° C.; and sulphur boiling point, 448° C.; then, with possible errors of 25° C., we have aluminium melting point, 650° C.; and gold melting point, 1,045° C.; and lastly, with possible errors of 50° C., are palladium melting point, 1,500° C., and platinum melting point, 1,775° C.

*Hydrogen Thermometers.*—Unworkable in furnace operations; glass cannot be used at high temperatures; metals are permeable to hydrogen when hot; porcelain is fragile, its enamel rarely sufficiently impermeable, and the joints are apt to give way by destruction of the mastic. Air is better than hydrogen, but both are only for the laboratory.

*Dilatation of Solids.*—Porcelain expands four millionths of its length per degree Centigrade; the expansion of silver increases from an average of 19·6 millionths between 0° and 100° to an average of 21 millionths per degree for temperatures between 0° and 890° C. Platinum has a more regular expansion than silver, but a smaller one (9 instead of 19 millionths); and in any case these expansions are very difficult to measure. Silver is soft when hot. A rod of platinum 4 in. long would have lengthened at 1,000° C. (1,832° F.) by less than  $\frac{1}{16}$  in.; but the greatest obstacle to this method is that metals, alternately heated and cooled, take up new sets and forms, which vitiate all the observations.

*Shrinkage of Clay.*—Wedgwood's pyrometer now quite abandoned; altogether too variable and irregular.

*Fusible Masses.*—Used with great success at the Sèvres potteries; made of the following mixtures:—

Temperatures of Fusion.	Felspar.	Kaolin.	Quartz.	Marble.	Iron Oxide.
° C.					
1,150	83·5	0·0	65	35	16·0
1,208	83·5	19·5	57	35	4·0
1,266	83·5	25·9	84	35	0·0
1,328	83·5	51·8	132	35	0·0
1,410	83·5	90·6	204	35	0·0
1,468	83·5	112·5	300	35	0·0
1,596	83·5	194·25	396	35	0·0

Intermediate compositions enable a scale of temperature (of about 25° per step) to be obtained. Better suited for watch-

ing a continuous rise in temperature than for preventing fluctuations.

**Fusible Alloys.**—Metals fuse abruptly: hence suitable if otherwise so; but mostly oxidisable. Alloys of silver, gold, palladium, and platinum are used; but they change in composition (liquefaction) and melt only gradually. Between two metals there is always one utilisable alloy which melts like an ordinary metal without liquefaction. For use, these metals and alloys are too expensive.

**Siemens' Electric Pyrometer.**—The electric resistance of metals increases rapidly with their temperature. Siemens' pyrometer, made on this principle, unfortunately does not remain constant in its readings, for the platinum wire employed becomes attacked by sulphur, silica, &c., unless it be enclosed in a platinum tube (iron will not do), which is too expensive.

**Speed of Outflow of Air.**—Mr. Barus has (*American Journal of Science*, 1889, 516) suggested a simple method. Air is driven through a tube; in its course it passes through two small orifices or capillary tubes—one of these is at the furnace temperature, the other at the ordinary. The things to measure are the changes of pressure at the obstructions; from these the temperature may be very simply calculated.

**Water Pyrometer.**—Boullier's. Water is made to circulate with a uniform velocity in a metallic tube exposed partially to the heat to be ascertained. Difficulties:—The cold tube in the hot gases condenses water vapour on it; upon the moisture settle down ashes and smoke. The muddy coating thus formed interferes with the absorption of heat.

**Calorimetric Methods.**—A lump of heated metal thrown into water; measure the rise of temperature in the water; calculate. The only metal the specific heat of which is really known is platinum. The quantity of heat lost by a kilogramme of platinum in cooling from  $t^{\circ}\text{C.}$  to  $t^{\circ}\text{C.}$  is, in great calories, equal to  $0.0317(t-t_0) + 0.000006(t^2-t_0^2)$ . The rise of temperature in the water should never exceed  $2^{\circ}$ , else errors due to radiation come in; and therefore the thermometers should read to  $\frac{1}{1000}^{\circ}\text{C.}$  But platinum and delicate thermometers of this kind are not for rough work; iron and a considerably greater rise in temperature are much resorted to. Consequently, results not reliable within  $100^{\circ}\text{C.}$ , and therefore of no use for calculating heat losses, &c., but still useful for regulating the furnace, if the same observer do the same thing under similar circumstances on each occasion. Iron in itself is an unsuitable metal, because at different temperatures it appears to undergo abrupt changes, and to evolve latent heat; this is apt to be confounded with the true cooling. Nickel is better in this respect.

**Optical Methods.**—(1.) The eye alone: The colour of the glow is watched. Dull red,  $525^{\circ}\text{C.}$ ; cherry red,  $800^{\circ}\text{C.}$ ; deep orange,  $1,100^{\circ}\text{C.}$ ; white,  $1,300^{\circ}\text{C.}$ ; dazzling white,  $1,500^{\circ}\text{C.}$  (Pouillet). (2.) The intermediate yellow part of the spectrum is cut out, leaving only the reds and blues; the change of tint is then far better marked. For this use, (a), a plain cobalt glass is employed, and the colour judged, which passes from red through white to blue; or, (b), Nonel and Masure's instrument—two Nicols with a quartz between. Rotation of one of the Nicol prisms causes a gradual change from red to yellow, green, or blue, according to the temperature of the object. The angle of rotation necessary to extinguish the red is observed. Chiefly useful for detecting variations in temperature.

**Thermo-electric Pyrometer.**—The method preferred by M. Le Châtelier. Becquerel, in 1834, proposed a palladium-platinum couple; first used by Pouillet, who employed iron instead of palladium; condemned by Regnault. Edmond Becquerel found a difficult formula for correcting the readings. The advantages are, small bulk, prompt equilibrium of temperature, reading taken at any convenient place or distance. According to Le Châtelier's results, (1), the couple should be composed of absolutely homogeneous wires which give no current when heated at any one point. Becquerel's, Pouillet's, Regnault's instruments did not fulfil this condition; iron and palladium do not do so. The condition is fulfilled by a couple consisting of platinum and an

alloy of platinum with 10 per cent. of rhodium, the readings given by which are consistent under all circumstances. (2.) The galvanometer ought to be one of high resistance, so as to maintain the intensity practically proportional to the electro-motive force. Galvanometers with movable needles are not adapted for rough work. Deprez and D'Arsonval's galvanometer works best, especially as modified by Le Châtelier with a view of hanging it in two parts on the wall. (3.) The couple may be graduated by plotting on square paper the indications given by boiling water, naphthalene, and sulphur, and by fusing aluminium, gold, and palladium, all which give known temperatures. The result is, with the platinum and rhodium-platinum couple, a curve which is almost straight between  $400^{\circ}\text{C.}$  and  $1,200^{\circ}\text{C.}$  The fusion-temperature readings of the metals are ascertained by putting a lithe wire across from the Pt to the Rh-Pt and gradually heating up. The galvanometer-reading gradually goes up as the temperature rises; it stops going up when fusion begins, and the current suddenly stops when the liquid bead of metal breaks. Once the graduation is accomplished, this thermo-electric couple at once gives, with the aid of the diagram, results correct within  $10^{\circ}\text{C.}$ , a result not hitherto attained. The inconveniences are, (1), that though a workman may use it, an electrician must put it up and graduate it; (2), that reducing (not oxidising) heated gases tend to alter the platinum, but this is much less felt than with the Siemens' instrument so long as the couple is not broken, and the wire is here thicker ( $\frac{3}{16}$  in.) and more durable. Still, it is well to expose no more than 2 in. of the wire, and to cover the rest with insulating porcelain in an iron tube, and in a reducing atmosphere, to cover the tip with an iron cap.

This instrument enables observation to become much more precise, and to give data exactly comparable as between one works, or one industry, and another.

#### *A New Method of Estimating the Oxygen dissolved in Water.* J. C. Thresh. Proc. Chem. Soc. 1890 (76), 1–3.

THE process is based on the observation that whereas, in absence of oxygen, nitrous acid and hydrogen iodide interact to form iodine, water and nitric oxide; in presence of oxygen the nitric oxide becomes re-oxidised, and, serving as a carrier of the oxygen, an amount of iodine equivalent to the oxygen present is liberated, in addition to that resulting from the initial action of the nitrous acid: hence, deducting the amount liberated by the nitrous acid and by the oxygen dissolved in the solutions used from the total amount, the difference will be that corresponding to the oxygen dissolved in the water examined.

The solutions used are: (1) a solution containing 5 grm. sodium nitrite and 20 grms. potassium iodide in 100 cc.; (2) a solution of 7.75 grms. sodium thiosulphate in 1 litre, 1 cc. of which corresponds to 0.25 mgrm. of oxygen; (3) a clear solution of starch; and (4) diluted pure sulphuric acid (1:3).

The apparatus required is as follows: A wide-mouth, white glass bottle of about 500 cc. capacity, provided with a caoutchouc stopper, through which four holes are bored. Through one passes the neck of a cylindrical "separator" funnel of known capacity, and through the second a tube drawn out to a fine point, which is connected by a short length of caoutchouc tubing with the thiosulphate burette; while inlet and exit tubes for coal gas are passed through the third and fourth holes, the exit tube having attached to it a sufficient length of caoutchouc tubing to permit of connexion being established between the bottle and the separator when the stopper of the latter is withdrawn.

The separator is filled with the water to be examined, and 1 cc. of the nitrite-iodide and 1 cc. of the acid solution are added; if the pipette be held vertically, with its end just below the surface of the water, the solutions flow in a sharply defined column to the lower part of the separator, so that an infinitesimally small quantity (if any) is lost in the water which overflows when the stopper is inserted. The admixture of the liquids having been effected by inverting the apparatus several times, a sharp current of coal gas is passed into the bottle to displace the air, the escaping

gas being allowed to burn at a jet attached to the exit tube. Fifteen minutes after adding the solutions to the water the flame is extinguished, a cork is attached in place of the jet and is inserted in place of the stopper of the separator, and the water is then allowed to flow into the bottle; the exit tube having been disconnected from the funnel and the gas set fire to, thiosulphate is run in until the colour of the iodine is nearly destroyed; about 1 cc. of starch is then added from the separator and the titration is completed. The effect of the nitrite, dilute acid and starch solutions is readily determined by removing the separator and adding 5 cc. of each in succession and then titrating; the effect of the oxygen in the thiosulphate may be allowed for on the assumption that as much oxygen is dissolved in it as distilled water would contain at the same temperature. It appears that there is no advantage in passing the coal gas through alkaline pyrogallol.

The author stated that concordant results were easily obtained, and that the results in the case of freshly distilled water closely agreed with those recently published by Roscoe and Lunt (this Journal, 1889, 729). Thus:—

Temperature.	Thresh.	Roscoe and Lunt.
°		
10	7.81	7.77
15	7.02	6.96
20	6.17	6.22
25	5.60	5.60
30	5.45	5.43

*Apparatus for Estimating Carbonic Acid in Carbonates.*  
Finkener. Mitt. k. techn. Versuchsanstalt, Berlin, 1889, 156—158.

THE apparatus represented in Figure, at one-eighth actual size, needs further description only in regard to one or two details. The joints are ground, and to give additional firmness are held together by external spirals. The limb *bg* is sufficient to condense for the most part, and return the

acid vapours from *a* kept gently boiling; at *g* is a plug of cotton wool, from *g* to *h* calcium chloride, from *h* to *c* phosphorus pentoxide. The accuracy of the results obtained with the apparatus is sufficiently shown in the numbers given, both for blank experiments and for determinations of carbonic acid.—C. F. C.

*Gravimetric Determination of Thiocyanates.* H. Alt.  
Ber. 22, 3258—3259.

THIOCYANIC acid when oxidised by nitric acid forms hydrocyanic and sulphuric acids, and this reaction is employed for the determination of thiocyanates, the sulphuric acid being precipitated as barium sulphate.

The thiocyanate is dissolved in water, an excess of crystallised barium chloride added, and then nitric acid, till the whole is strongly acid. The solution is warmed gently at first and then heated to boiling, to drive the

hydrocyanic acid out of solution. The resulting precipitate of barium sulphate is washed, dried, and weighed as usual. The method, compared with Volhard's volumetric process, gives satisfactory results.

The author states that the oxidation of thiocyanates by potassium permanganate in sulphuric acid solution is complete, but the liberation of hydrocyanic acid, and the fact that commercial thiocyanates usually contain some ferrous iron, render the process of little value. The decomposition taking place is represented by the equation—

—C. A. K.

*Separation of Zinc and Nickel.* H. Alt and J. Schulze.  
Ber. 22, 3259—3262.

WHEN sulphuretted hydrogen is passed into a strong succinic acid solution of zinc and nickel, the zinc is completely precipitated as snow-white sulphide, whilst the whole of the nickel remains in solution. The solution may be heated and an excess of the precipitant be employed without effect upon the accuracy of the separation. Test experiments were made with zinc sulphate and nickel nitrate, the salts being dissolved in water strongly acidified with succinic acid, and then treated with sulphuretted hydrogen. The precipitated sulphide of zinc was always quite free from nickel, whilst the analyses show that the separation is a quantitative one. In a mixture containing 22.66 per cent. of zinc and 20.39 per cent. of nickel, 22.66 per cent. of zinc and 20.19 per cent. of nickel were found. The succinic acid solution must be free from salts, otherwise nickel sulphide is thrown down with the sulphide of zinc. The way in which this is overcome, *e.g.*, in the case of an alloy containing tin, iron, copper, zinc, and nickel (German silver) is as follows:—The nitric acid solution of the alloy is concentrated, and the tin separated as oxide, and then the copper precipitated with sulphuretted hydrogen. The filtrate containing iron, zinc, and nickel is freed from sulphuretted hydrogen and the iron precipitated as basic acetate. An excess of precipitant should be avoided, owing to the necessity of removing the whole of the acetic acid before the zinc and nickel can be precipitated as carbonates; for a similar reason ammonium succinate cannot be used to precipitate the iron. After filtering off the iron precipitate, the small excess of acetic acid is removed by the addition of a little mineral acid, and the zinc and nickel precipitated as carbonates. These are filtered off, washed, and dissolved in succinic acid. The separation of the zinc and nickel can then be effected in an aliquot part of the resulting solution, by adding about 5 grms. of succinic acid, diluting with water and passing sulphuretted hydrogen into the boiling solution. The filtrate from the sulphide of zinc is concentrated and the nickel precipitated with caustic potash; the presence of much succinic acid in no way interferes with the complete precipitation of the nickel as hydrate.—C. A. K.

*Volumetric Determination of Combined Sulphuric Acid.*  
L. W. Andrews. Amer. Chem. J. 11, 567—571.

THE method is of general applicability. To the solution of the sulphate is added an excess of a solution of barium chromate in hydrochloric acid, the solution is neutralised with ammonia or calcium carbonate, and filtered; the filtrate is then acidified with hydrochloric acid, potassium iodide is added, and the free iodine is titrated with decinormal sodium thiosulphate solution.

A suitable solution of the barium chromate is prepared by digesting it with hydrochloric acid containing 36 grms. of acid per litre.

The analysis is carried out as follows: the sulphate to be determined is diluted until it does not contain more than 2 per cent. of  $\text{SO}_4$ , it is made approximately neutral, and is heated to boiling. While hot an excess of the barium chromate solution is gradually added, and the boiling continued for a minute or so. Calcium carbonate is next added in small quantities until no further evolution of carbon dioxide is observed. The whole is boiled, filtered

hot and washed. The filtrate after cooling is treated with a sufficient amount of crystals of potassium iodide, and with 5—7 cc. of fuming hydrochloric acid for each 100 cc. of liquid. Titration is then performed with thiosulphate, starch being used as indicator. In presence of ferric, nickel, or zinc salts ammonia must be used in place of calcium carbonate to neutralise the acid liquid.—T. L. B.

*On Crystalline Oxychloride of Mercury and the Estimation of Mercury.* J. Volhard. *Annalen*, **255**, 252—256.

THE oxychloride  $\text{Hg}_2\text{O}_2\text{Cl}_2$  was previously prepared by Millon and Ronches (Michaelis, *Lehrbuch der anorg. Chemie*, **3**, 1082); and Dietl (Tschermak, *Mineral. Mitth.* **1880** [2], **2**, 177). It may be easily prepared by adding sodium acetate to a cold saturated solution of mercuric chloride. In the course of some days crystals appear on the surface of the liquid, and as they increase sink to the bottom. They may easily be separated from a flocculent precipitate which is simultaneously formed. When the crystals cease to increase a solution of potassium bicarbonate is added, a little at a time, when a further crop is obtained. The crystals are granular, glossy, with rhombic faces; they appear to be very pointed rhombohedra. They rub down to a reddish-brown powder.

They have a sp. gr.  $\frac{17^\circ}{17^\circ} = 8.670$ . The substance is insoluble in water, easily soluble in acids, and decomposed by alkalis. On heating it is decomposed into the chloride, which volatilises, and the oxide which remains behind. The crystalline form was examined by Lueddecke, and the results are given in the paper.

It is known that mercury sulphide dissolves in caustic alkalis in the presence of alkaline sulphides. The author has found that it is completely precipitated from this solution by ammonium salts, and bases a new method of analysis on this.

The solution, which must contain the mercury as a mercuric salt, is nearly neutralised with sodium carbonate and then precipitated by ammonium sulphide, avoiding too great an excess of this latter, which should be freshly prepared. A solution of soda is then added with stirring until the dark liquid begins to brighten, when the solution is heated to boiling and more soda added until the liquid is quite clear. The soda must of course be pure, either potash by alcohol or soda from sodium may be used. The alkaline solution is precipitated by ammonium nitrate and boiled until all the ammonia is expelled. The precipitate is allowed to settle, which it does quickly, as it is much denser than the sulphide precipitated by sulphuretted hydrogen, washed with boiling water, and filtered off either on to a weighed filter or into a filtering tube. If it be feared that sulphur has been precipitated with the sulphide, it must be digested with sodium sulphite. In analyses of mercuric chloride by this method, the author obtained 73.86, 73.80, 73.85 per cent. of mercury respectively; 73.80 per cent. being the theoretical number.

—A. L. S.

*The Incineration of Vegetable Matter.* G. Lechartier. *Compt. Rend.* **109**, 727—731.

THE author finds that in determining the inorganic ash in vegetable matter by simple incineration in air there is a considerable loss of sulphur, but practically no loss of phosphorus. The former loss may be avoided by aspirating the volatile products through strong nitric acid.

The following is the method employed: The platinum crucible containing the organic matter is placed upon a clay plate which is heated in a gas furnace. The crucible is covered with an inverted glass funnel, which is fixed slightly above the rim of the crucible. The temperature is gradually raised, commencing at as low a temperature as possible. When the evolution of volatile organic matter ceases the bottom of the crucible is raised to a red heat for a few moments to complete the decomposition of the organic matter. The carbonised residue is washed with hot water and filtered through a washed filter-paper, which leaves no appreciable ash. The filter-paper and contents are introduced into the crucible, dried and heated to a dull

red heat. Incineration is rapid. The filtrate is then added to the incinerated ash, evaporated and the whole weighed, or the residue is treated with nitric acid previous to analysis. If on dissolving in nitric acid small particles of carbon separate out, these must be separated by filtration and again incinerated, for they may contain phosphorus.

For the estimation of phosphorus it is preferable to mix the matter with a quantity of milk of lime sufficient to moisten the mass throughout, which is then desiccated and incinerated.—J. B. C.

*Note on the Purification of Alcohol for Laboratory Uses.* E. Waller. *J. Amer. Chem. Soc.* **11**, 124—125.

THE alcohol is shaken up with powdered potassium permanganate till it is distinctly coloured. It is then allowed to stand for some hours until the permanganate is decomposed and manganese oxide is deposited. A small quantity of calcium carbonate is added and the alcohol distilled slowly. The distillate is tested until 10 cc. of it when boiled with 1 cc. of strong soda or potash gives no perceptible yellow colour on standing for half an hour. The subsequent distillate is collected for use; it is neutral and yields solutions with caustic alkalis and silver nitrate, which remain perfectly colourless even after boiling and standing for a long time.—E. E. B.

*Flashing Point of Lubricating Oils.* Holde. *Mitt. k. techn. Versuchsanstalt, Berlin*, 1889, 153—156.

THE two methods of testing oils for flashing point, viz., in an open crucible and in the closed apparatus (Pensky-Martens) usually employed at this institute, have already been shown to give results differing from 7° to 41° C. (this *Journal*, 1889, 734). Larger variations (to 150°) having recently been observed, the cause has been more closely investigated. Proof was obtained that the variations are due to the presence of small proportions of very volatile constituents. These may be either accidental constituents or may be added to bring a particular oil up to sample. The closed vessel test is of obvious importance for oils to be used in machines working with compressed air, such as torpedo engines.—C. F. C.

*The Distinction of Exalgin, Phenacetin, and Antifebrin.* Hirschsohn. *Pharm. J.* **20**, 710—711.

THE mixture (1 grm.) is treated with 2 cc. of chloroform, which dissolves the exalgin (methylacetanilide  $\text{C}_6\text{H}_5\text{M}(\text{CH}_3)(\text{CO}.\text{CH}_3)$ ) completely, but leaves the other two undissolved (*Pharm. Zeit. Russl.* Jan. 14, 17). Antifebrin in aqueous solution gives with bromine water a bromine compound, thus differing both from exalgin and phenacetin. Further chloroform solution of exalgin with 10 volumes of petroleum ether forms a clear mixture, whilst a solution of phenacetin or antifebrin is turbid under the same condition. Hirschsohn states that this method allows of the detection of an admixture of 20 per cent. of acetanilide or 10 per cent. of phenacetin with exalgin.

*Analysis of the Seed of Calycanthus Glauca.* H. W. Wiley. *Amer. Chem. J.* **11**, 557—567.

THE seeds of *Calycanthus Glauca* are poisonous, and bring death to a large number of American cattle. Eccles has discovered in the seed an alkaloid which he has named *calycanthine*. The present author examines more closely the occurrence of this alkaloid. The oil, which was removed from the seeds by petroleum spirit after crushing, was extracted with dilute sulphuric acid; the acid liquid, after being shaken with petroleum spirit to remove fat, was made strongly alkaline with ammonia and shaken with ether. The alkaloid thus obtained amounted to only 0.027 per cent. The seeds themselves, however, extracted similarly, gave 3—4 per cent.

Calycanthine crystallises from ether in feathery masses, insoluble in alcohol and in water. The colour reactions are interesting: Sulphuric acid, pale yellow; nitric acid, bright green; sulphuric acid + sucrose, purple, changing

finally to blue; sulphuric acid and potassium bichromate, brick red. The presence of sugar in the seed renders it possible to obtain the furfural reaction in the raw seed by the simple addition of sulphuric acid.—T. L. B.

*Adulterations of French Turpentine Oil. Qualitative and Quantitative Determinations.* A. Aignan. *Compt. Rend.* 109, 944—946.

French turpentine is frequently adulterated by the addition of resinous oils, though only to the extent of about 5 per cent., as a large quantity would render the oil viscous and give it a characteristic smell. Now by the addition of these resinous oils the rotatory power of the oil of turpentine decreases. That of the latter is nearly constant. With 16 different samples the numbers only varied from  $-60^{\circ} 26'$  to  $-63^{\circ} 20'$ . The average of  $[\alpha_D] = -61^{\circ} 30'$ . The white oils which are obtained by distilling colophony and further rectification may be divided into three groups. The purer the oils the greater their rotatory power. The oils possessing the following rotatory power are taken as typical:  $[\alpha_D] = -72^{\circ}$  or  $-32^{\circ}$  or  $-21^{\circ}$ .

These different qualities were mixed with oil of turpentine; the results of the determinations of  $[\alpha_D]$  are subjoined:—

Mixture with oil of first quality—

$$[\alpha_D] = -61^{\circ} 30' + \frac{7^{\circ} 30'}{5} h.$$

Mixture with oil of second quality—

$$[\alpha_D] = -61^{\circ} 30' + \frac{8^{\circ} 30'}{5} h.$$

Mixture with oil of third quality—

$$[\alpha_D] = -61^{\circ} 30' + \frac{9^{\circ} 30'}{5} h.$$

$h$  signifies the percentage of resinous oils contained in the mixture.

In certain cases oil of turpentine is mixed with essence of rosin, that portion of the products obtained in the distillation of colophony or pitch, which has the lowest boiling point. It may be detected by its characteristic and strong odour. The results of the above determinations may be summarised in the formula—

Oil of turpentine and ordinary essence of rosin—

$$[\alpha_D] = -61^{\circ} 30' + \frac{6^{\circ}}{5} e.$$

Oil of turpentine and refined resinous oils—

$$[\alpha_D] = -61^{\circ} 30' + \frac{3^{\circ}}{5} e.$$

$e$  denotes the amount of essence of rosin contained in the mixture.—A. R.

*An Application of Thermo-Chemistry.* A. Colson. *Compt. Rend.* 109, 743—745.

The author points out that thermo-chemistry may yield valuable data in determining methods of analysis of complex organic compounds, as, for example, the polybasic alkaloids. Thus, nicotine forms two salts with one and two molecules of acid. Thermo-chemical determinations show that the heat evolved in the case of the first molecule is double that of the second, and that, according to the results of Berthelot, the alkalinity of the second basic group should be too weak to effect litmus. The author finds this to be the case, and bases upon it a method of titration, using methyl-orange as indicator. He further finds that if the tin be precipitated from a solution of the pure double chloride of tin and nicotine, that titration indicates five-sixths of the total chlorine, four-sixths being derived from the tin, and one-sixth from the nicotine, another proof of the different basicities of the two basic groups in the alkaloid.—J. B. C.

*Estimation of Sulphur in Organic Compounds.* W. M. Burton. *Amer. Chem. J.* 11, 472—474.

The method is a modification of the method proposed by Sauer (*Zeits. Anal. Chem.* 12, 32 and 178), which consists in burning the substance in a current of oxygen, absorbing the sulphur dioxide in bromine water containing hydrochloric acid, and determining the sulphuric acid as barium sulphate.

As however the indicator, tropaeolin OO, is sensitive neither to carbonic acid nor to alkaline sulphites, it is practicable to absorb the sulphur dioxide in an excess of a standard solution of potassium hydrate, and titrate back the excess of alkali by means of a standard acid, using tropaeolin OO as indicator. The titration may be made immediately after the combustion is finished, and the operations of precipitating the barium sulphate, igniting, and weighing are avoided.

The apparatus is represented in the accompanying Figure.

The combustion tube is narrowed, as shown at A, the flask and bulbs C contain the standard alkali solution. D is a three-necked bottle, containing a layer of water, and fitted with a safety tube; at F this bottle is connected with the absorption bulbs, and at E with an aspirator for reducing and regulating the pressure in the combustion tube. After the substance has been completely burned, the tube is swept out by means of a current of air or oxygen, and the apparatus is allowed to cool. The combustion tube, the inlet tube for the oxygen, and the connecting tube  $d$  are rinsed with water to remove traces of  $\text{SO}_2$ , and the rinsings are added to the liquid in the absorption apparatus. A few drops of tropaeolin solution are then added, and the excess of alkali is titrated directly in the absorption apparatus. The standard sulphuric acid solution is made of such a strength that 1 cc. is equivalent to 5 mgrms. of sulphur; the standard alkali is made equivalent. If any of the halogens, phosphorus, or arsenic be contained in the substance under examination, this method, of course, cannot be used.

—T. L. B.

*Ash Determination in Raw Sugars.* G. F. Weichmann. *School of Mines Quarterly*, New York, 11, 15—23.

The old method of determining the ash in sugar consisted in carbonising the sample at a low heat, extracting the soluble salts by boiling water, and igniting the residue, adding this ash to the aqueous extract and evaporating to dryness. In 1864 Scheibler (*Zeits. Rübenzucker, Ind.* 14, 188) published his method of incinerating with sulphuric acid and deducting one-tenth.

Landolt (*Ibid.* 18, 68) holds that the weight of the salts in beet-sugars is about twice the weight of ash found by analysis. Boivin and Loiseau (*J. Fabrics. Sucre*, February 6, 1868) endorse Scheibler's method subject to the condition that the combustion is slowly conducted. Dubrunfaut (*Ibid.* December 18, 1870) considers Scheibler's "Factor 0.9 is nothing but a general average factor, which in many cases may be considerably far from the truth." Violette (*Ann. Chim. Phys.* [4], 29, 514) considers that the sulphuric acid method gives the weight of ash higher than the true weight. Von Lippmann (*Zeits. Rübenzucker Ind.* 31, 399) quotes experiments to prove that Scheibler's sulphate ash, less one-tenth, is exactly equal to the ash estimated as carbonate for beet-root sugars.

The author of this paper has made careful determinations of the ash of various kinds of raw cane and beet sugars both as carbonate (by a special method of analysis which is described in detail) and as sulphate. He finds that the results by the Scheibler method are almost without exception lower than those found by the other process. Direct experiment also proved that this was not due to loss of alkaline sulphates by volatilisation. Finally he finds that if the results by the Scheibler method be taken before the deduction of one-tenth they, in most cases, agree almost exactly with the results of the estimation as carbonate. He therefore endorses the recommendation of Dubrunfaut (*Le Sucre*, 1878, 2) that the sulphate ash as actually obtained be adopted as a working factor.

He says "the possible objection as to the expense of platinum muffles, where several must be used on account of the number of daily determinations, has been overcome in our laboratory by the use of muffles made of Russian sheet iron, which may be had at one-hundredth the cost of the platinum ware, which last on an average between three and four months, and which give absolutely no contamination to the sugar ashes burnt off in them."—A. J. K.

*Analysis of Marine Oils.* R. W. Moore. J. Amer. Chem. Soc. **11**, 155—158.

SOME marine oils examined by the author were found to prove an exception to the general rule, that natural fats and oils contain about 95 per cent. of insoluble acids. These marine oils are known as porpoise jaw and black-fish jaw oils, and are obtained from the soft fat of the head and jaw by cooling the oil which exudes from it and separating the portion which remains fluid. The resulting oil, skimmed and strained, is used for lubricating fine machinery. The samples of oil examined were:—

- 1 and 2. Porpoise jaw oil, skimmed and strained.
3. Porpoise jaw oil, not skimmed and strained.
4. Black-fish jaw oil, skimmed and strained.
5. Black-fish body oil.

The amounts of soluble and insoluble fatty acids were:—

	Soluble Fatty Acids.	Insoluble Fatty Acids.
	Per Cent.	Per Cent.
1 .....	17.18	72.05
2 .....	21.44	68.41
3 .....	.. ..	96.50
4 .....	21.79	66.28
5 .....	2.46	93.67

The acidity of the volatile fatty acids obtained by a modification of Reichert's process should be expressed as valeric acid, but for purposes of comparison with other analyses were calculated as butyric acid.

	Reichert's Figure.	Total Acidity.
	Cc.	Per Cent.
1 .....	47.77	17.18
2 .....	56.00	20.97
3 .....	2.08	1.42
4 .....	65.92	24.31
5 .....	5.60	2.34

In order to obtain satisfactory saponification numbers by Koettstorfer's process a large quantity of alcohol had to be used. Results:—

	Mgrams, KHO per Grm.
1 .....	253.7
2 .....	272.3
3 .....	143.9
4 .....	290.0
5 .....	197.3

The results yielded by Hübl iodine absorption process were:—

	Grms. of Iodine per 100 Grms.
1 .....	49.6
2 .....	30.9
3 .....	76.8
4 .....	32.8
5 .....	99.5

The oils which had received the full purifying treatment, 1, 2, and 4, were thus shown to furnish abnormally high

figures for soluble fatty acids and saponification numbers, and low figures for the insoluble fatty acids and iodine absorption, which indicates that the glycerides of the lower fatty acids have been concentrated in the oil which is finally strained off.

The author intends to examine butter fat by freezing it, straining and analysing the resulting product, and hopes in this way to obtain information regarding the composition of the molecular groupings in butter fat.—E. E. B.

*The Examination of Commercial Glycerin.* J. H. Wainwright. J. Amer. Chem. Soc. **11**, 125—130.

ALL so-called crude glycerin imported into the United States is examined at the United States Laboratory to ascertain whether it is really crude or has been partially or wholly refined, as in the latter case a higher rate of duty has to be paid. Crude glycerin may be freed from impurities by allowing them to subside and then straining or filtering them off, but if glycerin can be proved to have been submitted to further purification than this it is classed as "refined." For practical purposes of classification distillation is regarded as the dividing line between crude and refined glycerin. In order to distinguish between crude and refined glycerin the author attaches great importance to the estimation of the "carbonaceous residue."

Ten grms. of the glycerin are heated in a platinum crucible till it ignites, when the source of heat is removed and the sample allowed to burn away spontaneously. The residue is called "carbonaceous residue." In distilled glycerin this residue is rarely more than 0.5 per cent. and never as much as 1 per cent. (unless some adulterant is present which would be detected by other tests). Crude glycerin, on the other hand, frequently yields as much as 10 per cent. of carbonaceous residue. The ash may be determined by igniting the carbonaceous residue. The author regards as erroneous the statement of Sulman and Berry (this Journal, 1886, 177) that a definite distinction between crude and distilled glycerin is afforded by the amount of ash, and points out that in crude glycerin obtained by saponifying fats with steam the impurities are all organic and would consequently yield no ash. He has frequently met with samples yielding 3 per cent. of carbonaceous residues, but less than 0.05 per cent. of ash.

The silver nitrate and basic lead acetate tests are also considered very important.

*Silver Nitrate Test.*—5 cc. of the sample are diluted with 20 cc. distilled water, mixed with 5 cc. of a 2 per cent. solution of silver nitrate and allowed to stand for one hour. Only a slight precipitate will be formed with distilled glycerin at the end of this time, whereas with crude glycerin the precipitate is large, usually comes down at once and is almost always *flocculent*.

*Lead Test.*—The solution is prepared by boiling 10 grms. of lead acetate and 8 grms. of litharge with 500 cc. of water and filtering. Two volumes of this solution are mixed with one volume of glycerin and one volume of distilled water, and allowed to stand for one hour. Refined glycerin may produce a slight precipitate, but this is never *flocculent*. Crude glycerin produces a more or less abundant *flocculent* precipitate.

It is not safe to rely upon one of these last two tests alone, but if a sample of glycerin will not stand *both* of them it is perfectly safe to call it crude.

The other tests recommended as useful are:—

Addition of an equal volume of distilled water. *Refined* glycerin remains clear. In *crude* glycerin if much oil or fat be present they may be separated from the glycerin in this manner.

Ammonia. — *Refined*, no change; *crude*, precipitate indicates iron and alumina.

Ammonium oxalate. — *Refined*, no change; *crude*, precipitate indicates lime salts.

Barium chloride. — *Refined*, no change; *crude*, indicates sulphates.

Nitrogen peroxide (gas).—*Refined*, no change; *crude*, curdling indicates *fatty impurities*.

Fehling's solution.—*Refined*, no change; *crude*, shows the presence of *glucose*, &c.—E. E. B.

## New Books.

CHEMISCH-TECHNISCHES REFERTORIUM. Uebersichtlich geordnete Mittheilungen der neuesten Erfindungen, Fortschritte und Verbesserungen auf dem Gebiete der Technischen und Industriellen Chemie, mit Hinweis auf Maschinen, Apparate und Literatur. Herausgegeben von Dr. EMIL JACOBSEN. 1889. *Erstes Halbjahr*. Erste Hälfte. Berlin: R. Gaertner's Verlagsbuchhandlung, Hermann Heyfelder. London: H. Grevel and Co., 33, King Street, Covent Garden.

OCTAVO volume in paper cover; the first issue for the first half-year of 1889. It contains 132 pages of Subject-Matter, plentifully illustrated with wood engravings, and in these pages the following Subjects are treated of:—Building Materials, Cements, and Artificial Stone. Colouring Matters, Dyes, and Textile Printing. Fats, Oils, Illuminating and Heating Materials. Fermented Liquors. Tanning, Leather, and the Production of Glue. Textiles. Glass and Earthenware. Wood and Horn. India-rubber. Cements, Gums, &c. Lakes, Varnishes, and Paints. Metals.

ANLEITUNG ZUR CHEMISCH-TECHNISCHE ANALYSE ORGANISCHER STOFFE. Von F. M. HORN. Assistent für Chemische Technologie, derzeit an dem k. k. Technologischen Gewerbe Museum in Wien, früher an der k. k. Technischen Hochschule in Wien. 1890. Vienna: Verlag von Josef Safár. London: H. Grevel and Co., 33, King Street, Covent Garden.

OCTAVO volume, bound in cloth, price 5s. 5d. It contains 244 pages of subject-matter, illustrated by 32 wood engravings. The author has also collected together 35 Tables of the strengths, specific gravities of various solutions, spirits, &c. The following synopsis of contents will give an idea of the class of matter treated of and of the subdivision of the subject:—

*Section I.*—A. Pure Sugar Solution. B. Investigation of refined cane sugar, Cane Sugars, and Syrups. C. Analyses of Sugar Beets. D. Analyses of saturation deposit. E. Starch sugar (Glucose) Analyses. F. Milk sugar Analyses. G. Must Analyses. H. Animal charcoal Analyses.

*Section II.*—A. Investigation of varieties of Grain, of Flour, of amylaceous Cattle Foods, &c. B. Investigation of Potatoes. C. Dextrin. D. Malt and its extracts, worts, &c.

*Section III.*—A. Estimation of Alcohol generally (Spirits of Wine, Brandies, Arack, Rum, Cognac). B. Liqueurs and their Examination. C. Amyl Alcohol. D. Yeasts. E. Wines. F. Analysis of Tartars, &c. G. Beers. H. Glacial Acetic Acid, Vinegars, &c.

*Section IV.*—A. Milk Analysis. B. General Analyses of Fats, Waxes, &c. C. Butter Analysis. D. Analysis of Glycerin. E. Soap Analysis. F. Candles. G. Olein and Oleomargarin. H. Turkey-Red Oils. J. Lubricating Oils. K. Petroleum. L. Analysis of Etheral Oils. M. Balsams, Resins, and Gum Resins.

*Section V.*—A. Paper Analysis. B. Glue and Size Analyses. C. Analysis of Tanning Materials.

The work terminates with an Alphabetical Index.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

#### RUSSIA.

##### The Importation of Patent Medicines.

According to the *Journal de la Chambre de Commerce de Constantinople*, the import into Russia of patent medicines can only be effected conformably to Art. 310 of the Medical Regulations and Art. 151 of the Customs tariff, upon the authorisation of the Medical Council of the Ministry of the Interior, in conjunction with the Ministry of Finance.

The Medical Council only examines patent medicines to which the inventors have attached the detailed description of the various parts of which the medicine is composed.

#### RUSSIA.—FINLAND.

##### Changes in Customs Tariff.

*Note.*—Kilog. = 2·204 lb. avoirdupois.

Mr. J. Michell, Her Majesty's Consul at St. Petersburg, in a report to the Foreign Office, dated the 12th February, says:—

According to information supplied by Mr. Vice-Consul Cooke, of Helsingfors, the Imperial Finnish Senate has ordered the following changes in the Finnish Customs tariff:—

1. The duty on Chilian saltpetre imported into the Grand Duchy during the year 1890, should no instructions to the contrary intervene, to be fixed at 20 penni per 100 kilogrammes.

2. The duty on saccharine to be in future at the rate of 150 marks per kilogramme.

#### SWITZERLAND.

##### Classification of Articles in Customs Tariff.

*Note.*—Quintal = 220·4 lb. avoirdupois. Franc = 9 $\frac{1}{16}$ d.

The following decisions affecting the classification of articles in the Swiss Customs tariff were given by the Swiss Customs authorities in the month of January:—

Water of chloride of zinc.—Category 17. Duty, 1 franc per quintal.

Liquid carbolic acid in receptacles of wrought iron.—Category 18. Duty, 2 francs per quintal. This article was formerly in Category 9a, and paid a duty of 7 francs per quintal.

Fats serving for food not distinguished, cocoa fat (cocoa-nut oil, cocoa butter, cocoa-nut fat, cocoa fat), purified.—Category 188. Duty, 7 francs per quintal.

In Category 259 the words "not purified" are added after "cocoa butter (cocoa-nut fat)."

#### UNITED STATES.

##### Recent Customs Decision.

The following decision affecting the classification of articles in the Customs tariff and the application of the Customs law of the United States has recently been given by the United States Customs authorities:—

So-called "salol" is dutiable as a chemical compound under the provision in the Tariff Act of March 3, 1883 (T. I., 92), for "all chemical compounds . . . not specially enumerated or provided for."

## GOLD COAST.

## Customs Tariff.

The following is a statement of rates of import duty now levied in Gold Coast Colony:—Gunpowder, 6*d.* per lb.; lead in any form,  $\frac{1}{2}$ *d.* per lb.; kerosine and other illuminating oils, soap, and sugar, 10 per cent. *ad valorem*.

The following articles are exempted from duty:—Acids; blacking; blue indigo; candles; charcoal; chemicals; drugs and medicines; filters; glass; india-rubber; scientific instruments; matches; oils (except kerosine as above); ores; paints; pitch and tar; quicksilver; salt; methylated spirits; and tallow.

## VICTORIA.

## New Customs Tariff.

The following is a statement of the rates of import duty now levied under the new Customs tariff of Victoria, dated the 4th November last:—

Classification of Articles.	Rates of Duty.
Drugs, viz.:	£ s. d.
Acid, acetic, containing not more than 30 per cent. acidity .....	Pint or lb. 0 0 3
Do., do., for every extra 10 per cent. or part of 10 per cent. above 30 per cent. ....	" 0 0 1
Do., muriatic .....	Cwt. 0 5 0
Do., nitric .....	" 0 5 0
Do., sulphuric .....	" 0 5 0
Ammonia, carbonate of .....	Pint or lb. 0 0 2
Do., liquid .....	" 0 0 2
Chlorodyne .....	25 ° <i>ad val.</i>
Cocculus Indicus .....	Lb. 0 1 0
Gelatin .....	" 0 0 6
Glycerin, pure .....	" 0 0 3
Do., crude .....	" 0 0 1
Morphia .....	Oz. 0 1 6
Nitrate of silver .....	" 0 0 6
Nux Vomica .....	Lb. 0 0 2
Strychnine .....	Oz. 0 1 0
Earthenware, including packing (except photographic, scientific, and telegraph materials), measuring outside the package as imported .....	Cubic ft. 0 0 8
Explosives (except fine meal powder, not sporting, in bulk and in packages of not less than 25 lb. each), viz.:	
Powder, sporting .....	Lb. 0 0 3
Do., blasting .....	" 0 0 1
Other explosives (except gelatin and gelatin dynamite, the duty on which shall be 1 <i>d.</i> per lb.) .....	" 0 0 4
Glue, liquid, and liquid gum and cements ....	20 ° <i>ad val.</i>
Inks, writing, liquid or powder .....	10 ° <i>ad val.</i>
Oils:	
In bulk (except cocoa-nut, fish of all sorts, mineral refined of which the point of ignition is below 80° F., kerosene, palm lubricating, of which the chief component part is mineral) .....	Gall. 0 0 6
Kerosene .....	" 0 0 6

## Classification of Articles.

## Rates of Duty.

Classification of Articles.	Rates of Duty.
Oils— <i>cont.</i>	£ s. d.
Packed in bottles, jars, or other vessels not exceeding one gallon in size, as under:	
Quarts and over a pint .....	Dozen 0 4 0
Pints and over half a pint .....	" 0 2 0
Half pints and smaller sizes .....	" 0 1 0
Over a quart and not exceeding a gallon .....	" 0 12 0
Paints and colours (except artists' colours):	
Ground in oil, including patent dryers, and putty .....	Ton 2 0 0
Mixed ready for use, from or of any substance .....	" 4 0 0
Paper (except writing and printing in original wrappers and incut edges as it leaves the mill; paperhangings and millboard):	
Cut .....	Lb. 0 0 2
Advertising matter, printed or lithographed, or any printed plates, lithographs, pictures, cards, or matter of a similar description used or capable of being used for advertising purposes ....	" 0 0 4
Cardboards and pasteboards .....	Cwt. 0 4 0
Paper, other .....	" 0 6 0
Do. bags .....	" 0 15 0
Medicines, consisting of two or more ingredients, mixed ready for use, not being in chemical combination; drugs and chemicals packed ready for retail sale or consumption, including medical compounds containing spirits not exceeding the strength of proof by Sykes' hydrometer; and all preparations recommended as beneficial for any portion of the human or animal body, or the cure or the treatment of any disease or affection whatever; and medicine chests or cases, with or without fittings .....	25 ° <i>ad val.</i>

## JAMAICA.

## Customs Tariff.

The following is a statement of some of the rates of import duty now levied under the Customs tariff of Jamaica:—

Classification of Articles.	Rates of Duty now levied.
Gunpowder .....	Lb. 0 1 0
Indigo .....	" 0 0 3
Matches, per gross of 12 doz. boxes, each to contain 100 sticks .....	— 0 5 0
Oil .....	Gall. 0 0 9
Soap .....	100 lb. 0 5 6
Spirits of wine, alcohol, &c. ....	Gall. 0 10 0

The following are admitted free of import duty:—Dye-wood, guano and other manure, resin and rosin, rock salt, soda ash or sub-soda.

An export duty of 1*s.* per ton is levied on logwood and other dyewoods.

## EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

### CEYLON.

#### Industrial Undertakings.

In the course of the year 1889 a new oil works, with plant erected on European model, has commenced working in Colombo. The manufacture of biscuits from fine dried coprah is extending.

The following figures give some idea of the German share of Ceylon trade in 1889:—

—	Soap.	Spices.	Dyes.	Per- fumery.	Medicines.
	Rs.	Rs.	Rs.	Rs.	Rs.
Total imports..	121,563	211,339	78,979	69,014	175,317
German share..	27,795	6,348	3,534	3,033	1,665

### FRANCE.

#### Colouring Wine.

The Chilean Consul-General in London, in a communication regarding the use of the berries of a plant called the maqui for colouring wines, states that the maqui is a small evergreen shrub, common in Chili along the course of torrents and in shady mountainous woods. It is not cultivated, but grows wild, and the berries, which, in Chili, are eaten either fresh or preserved, are now beginning to be exported largely to Europe for the purpose of colouring wines. In the three years ending 1887 the exports were respectively as follows:—26,592 kilos., 136,026 kilos., and 431,392 kilos. To France alone the exports during the same years were, 500 kilos., 115,000 kilos., and 315,774 kilos. The berries are added to the grapes in order to give the wine a good colour.

### GERMANY.

#### Pharmaceutical Factories in Cassel.

Several firms in Cassel are engaged in the manufacture of surgical and pharmaceutical apparatus. They employ altogether about 500 workpeople, of whom 300 are women, and have an aggregate annual turnover of about 100,000*l*. The production of soaps in Cassel remains stationary at from 1,800 to 2,000 tons yearly, but in order to sell this quantity the makers have to content themselves with very low prices indeed. There are only about 50 workmen in this business, and their pay averages from 12*s*. to 15*s*. per week. There is one important firm of manufacturers of polishing pastes and powders who turn out their goods by means of machinery. They employ 30 hands, and pay the men from 1*s*. 10*d*. to 2*s*. 6*d*., and the women from 10*d*. to 1*s*. 2*d*. per day. They have great trouble to sell their goods in Germany owing to the excessive competition, but they find a good market for their surplus in the United States at remunerative prices.

### ITALY.

#### British Trade in Italy.

Some time ago the Italian Chamber of Commerce in London made inquiries from all the leading firms in Italy concerning their commercial relations with the United Kingdom, and the feasibility of the extension of their purchases from this country. The results of their inquiries were embodied in a long report, published in Italian, from which we take the following notes.

#### Fine Chemicals.

Mr. Melchiorre Petralia, pharmacist of Palermo, writes that in his district only the very smallest percentage of fine chemicals is imported from England, because articles of as good, if not better, quality are obtainable from Germany

at a lower price. Few, if any, of the finer pharmaceutical chemicals are made in Italy; but, on the other hand, all chemicals for current use are manufactured in that country.

#### Heavy Chemicals.

In 1888, writes Mr. Leo Negri from Liverpool, 11,604 tons of soda were imported into Italy from England, the value being 58,800*l*. France, Germany, and Austria also participate in this trade to some extent, but not seriously. Nevertheless, the imports of soda from England are diminishing, although the British article is generally preferred above any others, as its quality is better, and the sale conditions not so stringent. Mr. Negri does not think that there is any reason to believe that Italy will ever become independent from foreign countries for her soda supplies. Potashes are not bought in England at all. There are some factories in Tuscany, but they also do not produce much. The bulk of this article comes from Austria-Hungary, where the largest works exist. Britain, however, holds the field in bleaching-powder, hyposulphite of soda, nitric and carbolic acids, bichromate and chlorate of potash, phosphorus, carbonate of ammonia, nitrate of lead, &c.

#### Medicines.

Mr. Carlo Wiedemann, pharmacist to the German Emperor at San Remo, writes that the bulk of the goods purchased by him in England come under the denomination of proprietary medicines, for which he has a large sale among English residents in his district. He does not think it will be at all possible for Italian industry to compete in any way in this branch of trade.

#### Oils.

The export of linseed oil from Liverpool to Italy has been stopped altogether two or three years ago by the enormous duty put on the article by the Italian Government, and the four or five firms who were engaged in this business have given it up. It is thought that the Italian producers will gradually succeed in supplying the wants of the country independently of the foreigners.

### JAPAN.

#### Japanese Sulphur Mines.

The export of sulphur from Hakodate shows a decrease from 7,096 tons, value 16,917*l*., in 1887, to 3,609 tons, value 8,681*l*., in 1888. This is attributable almost entirely to the fact that no vessels could be induced to call at the port to take the sulphur away, the price, delivered in Hakodate (2*l*. 3*s*. 2*d*. per ton), being sufficiently high to prevent its being shipped. The shipments last year went to San Francisco.

What prevents Japan from rivalling Sicily as a sulphur-producing country are the absence of facilities for increasing the output of sulphur, and for shipping it. At present there is only one place where sulphur is worked on any scale, and that is Atosanobori, near Kushiro, on the south-east coast of the island on which Hakodate is situated.

The Atosanobori mine is part of an extinct volcano. The sulphur covers a considerable portion of the slopes of the hill and of the sides of the old crater. Supposing the ore to be only 4 or 5 feet thick on the surface, there must be at this place over 1,000,000 tons of high class ore. Recent borings (by Japanese) give the thickness of ore as 30 feet in some places, but it is probable that the richness of the ore decreases with the depth below the surface. It would be quite safe to count upon at least 5,000,000 tons of good ore. At present the ore yields over 50 per cent. of pure sulphur, a small portion of it being almost pure. The residue from the refining kettles would well repay a second treatment, as it appears to contain a considerable percentage of sulphur, as much as 15 per cent. probably, or about the average yield of the whole of the Sicilian sulphur ore.

The present output from Atosanobori does not exceed 10,000 tons of sulphur per annum (output about 9,000 tons in 1888). The cost of the sulphur, free on board at Kushiro, would be about 30*s*. 10*d*.

*Aniline Dyes.*

In spite of the fact that 1887 had already shown a strong increase in the import of aniline dyes over the preceding year, the figures in 1888 show a still further enormous increase; the imports have been in 1887, 306,884 cattie; and in 1888, 353,351 cattie, of which 249,443 cattie were imported directly from Germany. The most important aniline dyes for the Japanese market are the following:—Violet is still the most extensively used colour, although its sale is falling off, especially as far as concerns the commonest grade. Of blue, only best qualities are saleable, while the demand for magenta is very small compared with what it used to be, and only the best grades are still demanded. Green, in crystals, maintains its position, but powdered green has become almost obsolete. Brown, for silk-dyeing, is also declining in importance; eosin and erythrosin have become almost obsolete. The demand for good reddish tints of phloxin and scarlet is increasing. Corallin is now bought in lumps in England, this grade having superseded the powdered German article. The demand for picro, orange and yellow, is also on the wane; as regards orange only a few well-known brands which have an old reputation are still saleable, because they are the only ones which, mixed with phloxin, produce a certain colour which is much liked by the natives. Cotton red of the best quality finds a growing market. Alizarine dyes are gradually growing in importance, as the Japanese dyers are gradually surmounting the difficulties which they have hitherto experienced in using these dyes.

## NEW SOUTH WALES.

*Hints to Exporters.*

The import trade into Australia of chemicals, drugs, and medicines from Germany, says the German Consul at Sydney, could be easily increased to a considerable extent, but only by a close familiarity with the exact requirements of the local market. Perfumery also, eau de Cologne especially, is an article of very large consumption, and the same applies to toilet soaps. There should be an opening for goods of a superior grade. Natural mineral waters have not taken much footing yet, though some improvement is discernible. In general, it may be said that it depends, to a very large extent, upon the personal qualifications of the local representative whether a certain new article or unknown brand can be successfully introduced. Advertising is also a very large factor here, and British and American firms frequently spend large sums upon the introduction of their specialties by this means. If once an article has been successfully introduced, it is absolutely necessary to keep a sufficient stock always available here.

*Acetic Acid.*

In 1886 the imports of this article into New South Wales were 5,341 gallons, and in 1887 only 3,022 gallons. The German share of this trade was about 2,000 gallons each year, while the English business fell off considerably in 1887. The German acid, being concentrated, is about 30 per cent. dearer than the English.

## PERSIA.

*Gum Arabic.*

It is well known how the recent wars in the Soudan and the isolation of those tracts have affected the supply of gum. The effects of this are now being felt in Persia, where gum is now being extensively collected from the wild almond, "gavan," and other shrubs and trees, and measures are being taken to prevent the wholesale destruction of such woods. The exports during the last two years have been as follows:—

	Shiraz.		Bnshire.		Bunderabbas.	
	Cwt.	Value £	Cwt.	Value £	Cwt.	Value £
1888	485	940	7,917	7,977	6,010	1,836
1889	485	940	4,149	4,149	6,430	3,113

*Drug Trade Statistics.*

The following are the figures of imports and exports:—

*Imports.*

	Shiraz.	Bushire.	Bunderabbas.	Lingah.
	£	£	£	£
Drugs and medicines	1,458	6,359	3,004	1,293
Glass and glassware.	2,120	8,204	..	..
Indigo .....	40,831	25,985	8,676	..
Oil .....	1,701	5,251	535	4,685
Spices .....	10,719	7,176	5,482	6,481

Gum .....	940	7,977	1,836	..
Opium .....	230,886	148,523	127,393	..
Perfumery .....	5,401	9,466	..	..

*Opening of the Karoon.*

The most important event of the year 1888 was the consent of the Persian Government to throw open the River Karoon as far as Ahwaz to vessels of all nationalities; the ulterior object is, of course, to develop the shorter route for traffic between the sea and Central and Northern Persia. The project in itself is feasible and promising, but its success must largely depend on the measures adopted by the Persian Government to improve roads and secure their safety, to remove undue restrictions and taxation, and allow commerce fair play generally. The route was promptly inaugurated by Messrs. Lynch and Co. running their steamer *Blosse Lynch* between Busrah and Ahwaz experimentally. The success of the Karoon route will doubtless cause some redistribution of trade in Persia, but it may safely be predicted that the general prosperity of the country will be increased.

## SERVIA.

*Piracy of Trade Marks on Druggists' Goods.*

Among Servian imports there are a large quantity of the most shameless falsifications of British trade marks, which are openly resorted to, at the expense of the customers, and to the great danger of our reputation. Amongst such goods are:—Atkinson's scents, lozenges labelled "Savory and Moore," and soap stamped "SOAP" on one side, and manufactured by Messrs. Mousson and Co., Frankfurt-on-the-Main.

*Mineral Waters.*

A monopoly for the manufacture of mineral waters has been granted to Mr. Johann Erlicher, of Belgrade. The concession is exempted from the payment of imported duties for articles and machinery required for the business for 15 years, and the produce of the manufactory may be exported free during 10 years. The concessionaire is bound to begin work within 12 months.—*Chemist and Druggist.*

## MISCELLANEOUS TRADE NOTICES.

INTERNATIONAL EXHIBITION OF MINING AND METALLURGY  
IN LONDON.

During the summer of this year an International Exhibition of Mining and Metallurgy will be held at the Crystal Palace, Sydenham. The offices of the honorary secretary of the exhibition are at 18, Finch Lane, E.C. The following is a summary of the branches which will be represented:—

Machinery in motion and at rest; gold mining; silver mining; diamond mining; ironstone and iron ore mining; the manufacture of iron and steel; lead mining and manufacture; tin mining and smelting; copper mining; zinc mining and manufacture; coal mining; the petroleum industry; natural asphalt mining; mining for precious stones; the salt industry; mining for antimony, quicksilver, asbestos, arsenic, manganese, cobalt, platinum, bismuth, ochres, sulphur, uranium, and other minerals; alloys; the nitrate and phosphate interests; assaying, &c.; chemicals and the chemistry of mining and metallurgy; quarrying; clays; cement; electricity; explosives; the transport and shipment of minerals; scientific instruments; collections of mineral specimens; mining and metallurgical literature; mining tools and appliances; ambulance practice; and the condition of working miners.—*Board of Trade Journal*.

## METALS IN RUSSIA.

The Russian *Nouveau Temps* has published a comparison between the latest report of the Russian Mining Commission, edited by M. Koubeline, and that published in 1878 by M. Skalkovsky. The report does not give any figures later than the end of 1887, but the comparison supplies important data for measuring the progress of the Russian metal industry.

So far as the precious metals are concerned, the product of gold has fallen during these 10 years from 2,572 to 2,128 pounds, while that of silver has increased from 699 to 939 pounds, and that of platinum from 126 to 269 pounds. The figures are different for the precious metals chemically refined, namely, 1,898 pounds of gold and 1,043 pounds of silver in 1887. Those for platinum are unknown, the melting of that metal being mainly carried on abroad. Notwithstanding the affinity which exists between silver and lead, and the increase in the produce of silver, less lead was extracted in 1887 than was the case 10 years before—60,428 pounds instead of 85,281.

It is a misfortune for Russia that the amount of gold extracted is less than it used to be. It appears that less and less auriferous soil is discovered in the region of Yakontsk. On the other side, the fact that more gold is found in the quartz mines than formerly (164 pounds instead of 87) is of favourable augury for the future. It is not believed by Russian economists that there will be much progress in the gold industry until the great Siberian railway is finished, as this scheme takes away the labourers from all other work, and makes the price of machinery abnormally high. The only progress of the gold industry at the present moment is found in the province of the Amour.

Foreign competition has for a long time past been injurious to the production of copper, but the raising of the Customs tariff has made an alteration, by which the Caucasus has benefited. In 10 years the melting of copper has risen from 214,865 to 304,607 pounds. On the other hand, zinc has fallen from 283,398 to 221,250 pounds, in consequence of the decline of the home demand. Very little tin is obtained in Russia (629 pounds in 1887), and that only in Finland. Quicksilver, a rare metal, was not worked in Russia until 1886, but in 1887, 3,911 pounds of it were obtained. During the 10 years the extraction of manganese rose from 11,790 in 1878 to 3,553,535 pounds in 1887. In 1886, however, the figure was a million pounds higher; the sudden fall is due to the rivalry of Chili. There was also in 1887 a temporary diminution in the product of coal, but the 10 years show a great increase, from 153,981,727 to 276,778,774 pounds. It is in Poland and in the region of the Donetz that the quantity

of coal extracted has doubled, while it has diminished in the neighbourhood of Moscow and on the Kirghis Steppe. Fifty-eight per cent. of the coal consumed has been by the railways, of which, however, 16 per cent. was of foreign extraction.

Gigantic progress has been made in the working of naphtha. The manifest exhaustion of the American wells of good quality promises for Russian petroleum the ascendancy in the market of the world. During 10 years the product of Russian raw naphtha has risen from 15½ millions to nearly 167 million pounds. The asphalt industry is concentrated at Syzran. Since the abolition of the excise duty on salt, the extraction of that article has been greatly encouraged. The stimulus given to the iron trade by the protectionist system cannot be estimated by any figures given in the new report, for that system was only first applied in 1887.—*Ibid*.

## UNIFORMITY OF INDIAN WEIGHTS.

According to the *Pioneer Mail* for the 5th February, the Government of India have addressed the local governments regarding the practicability of securing a uniform system of weights in all India. That which appears the best solution, according to the Government, is the tolah of 180 grains, which is the exact weight of the rupee; the seer of 80 tolahs; and the maund of 40 seers. All railways have adopted these weights, and the tendency of trade will naturally be to follow this example. The local governments are asked to take the opinions of the principal trading associations before forwarding their replies.—*Ibid*.

## THE MINES OF CANADA.

The following information respecting the mines of Canada is extracted from the Canadian Official Handbook for 1890, the issue of which was notified on p. 202 of the February number of the *Board of Trade Journal*:—

*Mines*.—The exports under this head are chiefly coal, gold, copper, iron phosphate, salt, antimony, mineral oils, and gypsum. Gold mines are worked to a small extent in Ontario, Quebec, and the territories, but largely in Nova Scotia and British Columbia, the production from these two provinces in 1887 having amounted to 1,108,173 dols., and in 1888 to 1,050,670 dols. In British Columbia there are yet immense fields to open up. Silver mines are being worked in Ontario; and that at Silver Islet, Thunder Bay, has been the richest yet discovered in Canada. There are various deposits of minerals of all kinds in British Columbia. Iron ore is found all over the Dominion, and many mines have been successfully worked. Some of the Canadian iron ores are among the most valuable in the world. Copper is mined to a considerable extent both in Quebec and Ontario, and the deposits of the ore are of great extent.

There are very large coal deposits in Nova Scotia, and many mines are profitably worked. The coal is sent up by the river St. Lawrence and by rail into the interior. The coast of British Columbia is very rich in coal of a quality which commands a preference to the markets of San Francisco, notwithstanding the United States coal duty. Tests made by officers of the United States Government showed the British Columbia coal to excel that of California, Washington Territory, or Oregon, by one-fourth in steam-making power.

As regards the North-West territories, coal is known to exist over a vast region on and to the east of the Rocky Mountains. This region stretches from 150 to 200 miles east of the mountains, and north from the frontier for about a thousand miles. In places where the seams have been examined they are found to be of great thickness and of excellent quality. Beds of true bituminous coal have been found. There are also large quantities of lignite, which, for local use, where wood is scarce, will prove to be a useful fuel. It also occurs in considerable quantity along the valley of the Souris River, near the frontier, 150 miles west of Winnipeg. Good seams of anthracite coal are being worked in the Rocky Mountains at Anthracite and Canmore, and all these coals are now carried east and west by the

Canadian Pacific Railway—a fact of the greatest importance to settlers on the vast fertile belt of treeless prairies east of the mountains.

Specially among the minerals which are used for agricultural purposes may be mentioned apatite or phosphate of lime. The increasing demand for this valuable material has led to a great increase in production, both for home use and exportation. In 1887, 23,152 tons were exported, and the shipments in 1889 are estimated at 25,000 tons. The attention of the Canadian farmers is being directed to the valuable properties of this mineral as a fertiliser. The percentage of purity of native Canadian phosphate reaches from 70 to 95 per cent. It produces valuable results when applied to land in its raw state, reduced to a fine powder. But the conditions for manufacturing it into superphosphate are also favourable in Canada. This raw phosphate of lime commands a price from 25-50 dols. (about 5*l.* 2*s.* sterling) per ton in Liverpool, as appears by a recent market quotation. Phosphate of lime is found in large and easily-workable deposits throughout a large extent of country in the Ottawa Valley. The largest deposits have been found on the Quebec side.

Petroleum is known to exist in several parts of the Dominion, but the wells have only been profitably worked in Ontario. The production from them is very large, and appreciably adds to the wealth of the Dominion. Very extensive sources of petroleum have also been found in the North-West and in the Rocky Mountains.

Salt is found in the North-West; but the principal deposits are at Goderich and other places in Ontario, where there are extensive salt works. Salt is also found in New Brunswick.

Building stone of excellent quality is widely distributed in all the provinces, and there are numerous quarries of dolomite, limestone, sandstone, and granite, from which blocks of every size required can be obtained. There is also a great variety of marbles, but only a few quarries have yet been opened.

Gypsum is found in great abundance in New Brunswick, Nova Scotia, and Ontario. It occurs also in Manitoba and the territories. It may be procured at a cheap rate in any of the older provinces as a fertiliser.

Excellent peat is found in large deposits in all the provinces.—*Ibid.*

#### COPPER IN CANADA.

The copper deposits in Eastern Quebec, operated for many years, are those known as the Capelton mines. They are situated about seven miles south of Sherbrooke, the principal city of Quebec east of the St. Lawrence. At the time of the great copper boom, a number of mines were opened in this section. While at many of these places the veins promised well at the time, the gradual decline in the price of copper, and the generally low grade of the ore, rarely yielding more than 4 to 7 per cent., resulted in a gradual suspension of most of these enterprises. At the present time, while prospecting is again being resumed with some vigour, mining is confined almost entirely to two locations at Capelton, viz., the Nichols and the Eustis mines. The continued success of these workings has been due to several causes. One, probably, is the great size of the vein, which is stated to reach, in places, a thickness of 45 to 60 feet, and has been worked to a depth of over 1,500 feet. A chief cause, however, is that these ores are rich in sulphur, the bulk of the raw ore being used, first of all, for the manufacture of sulphuric acid, the residue being subsequently utilised for the extraction of the copper. A certain percentage of silver in the ore is also, doubtless, a very important factor as regards their present successful working, the amount at times ranging as high as 10 to 12 oz. to the ton, and probably even higher, though probably 3 to 4 oz. represents the average. The output of ore from these mines is large, ranging from 30,000 to 40,000 tons per year for each. While the greater part of this product is shipped in the raw state, smelting works, recently repaired by the Eustis Company, now dispose of over 1,000 tons per month, which is reduced to matte on the spot. At the Nichols mine adjoining, a correspondingly large amount is used for the manufacture of acid. A portion of the latter, with the phosphate of the Ottawa Valley, is converted into

superphosphate of lime. This industry, in the not distant future, bids fair to assume very large proportions.—*Iron-monger.*

#### EXPORTS OF CHEMICALS FROM THE TYNE FOR THE LAST THREE YEARS.

	1889.	1888.	1887.
	Tons.	Tons.	Tons.
Alkali and soda ash .....	17,632	27,054	35,112

—*Chemist and Druggist.*

#### DISCOVERY OF BRINE AT MIDDLEWICH.

It is reported that a large quantity of brine has been discovered at the shaft which has been recently sunk on Newton Farm, Middlewich. The brine, it is said, has risen in the shaft to a height of over 70 yards, the strength being 2 lb. 10 oz. of salt to the gallon. The total depth of the shaft is about 100 yards. The first bed of salt is 60 feet thick, and 12 yards below this a second bed has been discovered, yielding at a depth of 56 feet a very fine quality of amber rock-salt. The discovery has caused some excitement in the salt trade.—*Ibid.*

#### A CHANCE SULPHUR PROCESS COMBINATION.

The alkali makers, who are preparing to recover sulphur by the Chance process, met at Liverpool lately for the purpose of devising a scheme for selling the whole of their produce, so far as it is intended to be placed on the open market, through a single medium and at a uniform price. In view of the already very depressed condition of the sulphur market, such a combination alone can prevent the manufacture under the Chance process from becoming absolutely unremunerative, as, apart from that process, there is already a much greater quantity of sulphur offering on the market than can be assimilated. Mr. Chance, the patentee of the new process, presided over the meeting, and after some discussion it was decided to form a limited company expressly for the sale of the product. It is thought that the quantity of Chance sulphur available for the market during the first year will represent a value of between 40,000*l.* and 50,000*l.*, the bulk of which will be manufactured at Widnes and St. Helens. Four-fifths of the producers were represented at the meeting.—*Ibid.*

#### SOAP IN INDIA.

There is an ample demand for the increased use of soap in India, for at present, after allowing for local manufacture, it may be said of the people of India that soap is to them

an unknown luxury, the consumption being at the rate of less than a shilling's worth for every hundred inhabitants a year.

The imports of soap have, it is true, more than doubled during the last six years, and the trade is steadily increasing from year to year. It is not anything like a large trade even now, for the largest quantity yet imported, that of the year ending April 1889, reached only 71,000 cwt., the value of which was 102,289*l.* The bulk of this was from England, the other European States supplying only a little over 3,000 cwt. The soap factories at Bombay, Jeypore, and Meerut are doing well and increasing their out-turn, and the local demand will most probably now go on increasing from year to year.

The soap manufactured by these companies is much liked by the natives, and particularly that variety called "vegetable" soap is in much request. Hindus of the orthodox type would not touch a soap made of tallow or animal fat, as it is against the principles of their religion to do so. Such men and women in general, therefore, did not use soap at all, and contented themselves by cleaning their hands with simple earth, or the soap-nuts of species of *sapindus* and the legumes of *Acacia concinna*. Since the production of the vegetable soap the objection to the introduction of that article in the native Hindu household is overcome, and soap is beginning to replace the primitive clay and vegetable substances used. About 8,000 cwt. of native-made soap is now exported annually.

The imports of soap of all kinds into British India have been as follows in the last six years:—

	Cwt.
1883—84.....	31,447
1884—85.....	38,975
1885—86.....	49,804
1886—87.....	59,016
1887—88.....	61,139
1888—89.....	71,072

The imports since this have, however, been declining. Of 500,000 cwt. of British soap which we exported in 1888, 75,275 cwt. went to India.—*Journal of the Society of Arts.*

#### A LARGE SALT FIELD.

At the annual meeting of the Stockton-on-Tees Chamber of Commerce, the president stated that the Teeside salt field covered an area of 11 square miles, averaging 70 feet in thickness, although in some places it was as thick as 100 feet. Each acre contained about 200,000 tons of salt, and the district contained enough to supply the whole world for 800 years.—*Industries.*

#### EFFECTS OF THE LATE STRIKES.

The effect of the strikes of the English colliers and of the Liverpool dock labourers has been greatly to reduce the supplies to the United States of alkali products, soda ash, caustic soda, bleaching powder, bicarbonate of soda, and allied chemicals used by the makers of glass and paper. The prices of these articles have much increased, and some have even more than doubled in cost. The result is that trade has been much disturbed, and the establishment of home factories for these materials is projected. The increased cost of camphor is attributed, not to the shortness of the crop, but to the enormous consumption in France and Germany for smokeless powder.—*Standard.*

#### A LARGE MANGANATE OF SODA CONTRACT.

At the weekly meeting of the London County Council, held at the Guildhall on March 18, the seal of the Council was, on the recommendation of the Main Drainage Committee, affixed to a contract with Messrs. C. Tennant, Sons, and Co., for the supply of 1,200 tons of manganate of soda at 12*l.* per ton; and a contract with the Widnes Alkali Company for the supply of 800 tons at 12*l.* per ton.—*Chemist and Druggist.*

#### THE OPIUM CROP IN THE TURKISH EMPIRE.

The following statistics give the production of opium in the whole of the Turkish Empire in Asia and Europe during

the last 26 years, together with the highest and the lowest prices of opium (in Turkish and British currency) on the Smyrna market during the seasons in question. The figures show that since 1864 there have been 128,400 baskets of opium produced in the Turkish Empire, the Persian production not being included in the returns. Deducting from this total the stock of opium now believed to be in existence, viz., 4,800 baskets (1,400 baskets in Smyrna, 700 in Constantinople, 1,700 in London, and 1,000 in America, &c.), we have an average annual consumption, during the last 26 years, of about 4,750 baskets of opium.

The comparatively large crops obtained since 1868 are explained by the fact that until that season the cultivation of the poppy was restricted to four or five provinces in Anatolia (Konieh, Karahissar, Sourahan, Bogaditch, and the neighbourhood of Smyrna), but after 1869, when the failure of the crop had caused an immense advance in the price of the drug, the cultivation was extended to other parts of the Empire, over the whole of Northern Anatolia, and in Roumelia. Since that period the peasants became accustomed to the cultivation of the poppy, and the prices thenceforth became dependent only upon the greater or smaller yield of the crop. It is said that the future of the opium industry in Turkey is becoming more uncertain. The extension of the railway system especially operates against the continuation of opium cultivation, because it encourages the growing of cereals, which require less attention, are less easily destroyed by inclement weather, and for which the demand is not so much influenced by speculation:—

Year.	Yield of Crop.	The Smyrna Prices during the Season.			
		Highest.		Lowest.	
	Baskets.	Piast.	s. d.	Piast.	s. d.
1864	3,400	140	16 6	111	13 0
1865	4,350	130	15 2	94	11 0
1866	1,350	160	18 8	122	14 0
1867	3,000	170	19 10	120	14 0
1868	1,600	390	45 6	146	17 0
1869	3,500	295	34 5	180	21 0
1870	4,300	270	31 6	130	15 0
1871	8,500	200	23 4	130	15 0
1872	4,400	220	25 8	170	19 1
1873	3,150	260	30 4	165	19 0
1874	2,430	274	32 0	130	15 0
1875	6,390	145	16 11	122	14 0
1876	3,250	190	21 6	137	15 0
1877	9,450	138	15 8	122	13 10
1878	6,050	145	16 5	120	13 7
1879	4,300	250	28 4	135	15 3
1880	2,100	250	28 4	135	15 3
1881	11,000	135	15 3	103	11 8
1882	4,500	135	15 3	90	10 2
1883	6,970	115	12 10	85	9 6
1884	5,400	115	12 10	90	10 0
1885	7,400	95	10 7	80	8 11
1886	7,600	164	18 0	63	6 11
1887	1,800	189	19 10	71	7 10
1888	7,300	100	11 0	62	6 10
1889	5,000	..	..	..	..

—*Ibid.*

## OPIUM IN BRITISH INDIA.

Under an agreement with the administration of the opium department of the Bombay Presidency, and with the view of effectually stopping the contraband traffic in opium, the rulers of all native States, except Baroda, have consented to entirely prohibit the cultivation of the poppy in their dominions. Baroda has been permitted to grow and manufacture opium, under a State monopoly, for consumption in its own territory, and for export to China. The State has undertaken to assimilate its opium retail system and selling prices to those for the time being in force in adjoining British districts, and to prevent the introduction of Baroda opium into British territory, and into the territories of adjoining native States.—*Ibid.*

## OPENING OF SULPHURIC ACID WORKS.

The long-closed sulphur works at Tauranga, 100 miles south of Auckland, are about to be opened, and utilised in the manufacture of sulphuric acid, by Messrs. Sharland and Co., of Auckland. The works are now being put in order and are expected to be in operation early next month. On a small islet called White Islet, some miles off the coast, there is an inexhaustible supply of crude sulphur in a high degree of purity, but owing to the lessee and part owner of the island refusing to allow it to be worked, this source is not available; but at Matata, some 50 miles south of Tauranga, there is another enormous deposit of sulphur. Other localities, too, not far removed, are rich in this element, and the proprietors of the works will have no difficulty in obtaining supplies.—*Chem. Trade Journal.*

## FRENCH COAL PRODUCTION IN 1889.

Comparative tables relating to the coal production in France have recently been prepared and issued by the French Government. From these tables it appears that the total production of coal in France in 1889 amounted to 24,588,880 tons, as compared with 22,602,894 tons in 1888, an increase of 1,985,986 tons. The largest quantity came from the Department of the Pas de Calais, namely, 8,624,837 tons, while the Nord furnished 4,809,065 tons, as compared with 4,416,185 tons in the preceding year. The Loire comes next with 3,378,138 tons, the Gard with 1,976,511 tons, and the Saône et Loire with 1,491,279 tons. In the Departments of the Pas de Calais and the Nord, the largest quantity of coal extracted came from the mines of the Anzin Companies, the amount being 2,857,613 tons; the Lens et Douvriin Company comes next with 1,667,398 tons, and the Courrières Company with 1,188,635, the increase in the production in 1889 over that of the preceding year being 262,032, 255,747, and 95,435 tons respectively. The increase in the total production of these two departments amounts to 1,057,413 tons, the actual amounts being 13,433,847 tons in 1889, against 12,376,434 tons in 1888.—*J. Soc. Arts*, 1890, 443.

## THE SUGAR PRODUCTIONS OF THE WORLD.

An extremely able and interesting report on the "Progress of the Sugar Trade," by Robert Giffen, Esq., LL.D., Assistant Secretary, Commercial Department, Board of Trade, was presented to Parliament in May of last year, and issued to the public in the month of June following. For an early copy of it this establishment was indebted to the Board of Trade. The whole document deserves the most careful study, but it is unlikely in its complete form to circulate to any large extent in the colonies. It seems desirable, therefore, to extract some passages which contain information in a very condensed form on the production, consumption, and, to some extent, distribution of sugar.

There is some risk, no doubt, that by detaching passages from a document of this kind a different impression may be produced to that which would be derived from the whole. The passages now reproduced deal, however, with statistical matters of fact, which are not affected whatever view is taken of their significance.

Taking the period 1853—87, the production of cane sugar has more than doubled, and British and foreign cane sugars

have preserved about the same proportion. In 1887 British cane sugar formed about one-fifth of the whole production of cane sugar and about one-ninth of the total sugar production of the world. The development of the beet sugar industry is brought out in the most remarkable way. At the beginning of the period it formed only one-eighth of the total sugar production; at the end it amounted to nearly a half.

Taking the West Indies and British Guiana together, it appears that since 1883—85 the production of cane sugar has pretty well held its own; but if the production of the West Indies be taken separately, it "has not maintained itself so well."

Turning now to consumption, it appears that there has been a falling off, during the period 1877—88, in the importation of raw cane sugar into the United Kingdom from British possessions, "particularly the West Indies," of nearly  $2\frac{1}{2}$  million cwt., the greater part in the last five years. Foreign raw cane sugar over the same period ends with a slight decrease. On the other hand, the West Indies have found a market elsewhere, particularly in the United States. The importation of beetroot sugar during the same period has more than doubled. And it is important to notice that during the last five years, while the import of raw beet sugar showed little increase, that "of refined in the same period has been over three million cwt., or as much as the total imports of refined from beet countries five years ago."

The production of cane sugar in British possessions show "that that production does not find an outlet in the market of the United Kingdom, as it formerly did, its place being taken by beet sugar."

The figures with regard to home consumption are very striking. "The 8 million cwt. consumed 30 to 35 years ago, inclusive of duty, were as costly to the consumers of the United Kingdom as the 22 million cwt. annually consumed in the last two or three years."

In the June Bulletin for 1887 the position of the sugar question in the West Indies was briefly touched upon. There is reason to think that to some extent sugar has slightly gone out of cultivation. When this has happened the particular loss is irreparable. The necessity of keeping the land clean and in tillage, and the machinery in working order, is so paramount that there can be no doubt a sugar planter will strain his pecuniary resources to the uttermost before throwing his estate out of cultivation, because once a sugar planter is compelled to suspend operations, even for a short period, the capital invested is lost beyond hope of recovery. The usual sequence of events, when an estate is abandoned in the West Indies, is that the workpeople are scattered and leave the neighbourhood, the land becomes foul, the buildings ruinous, the working oxen are sold, necessarily at the loss incidental to a forced sale, and the machinery, in spite of every precaution to keep it in order, becomes rusty and useless. Hence it will be no matter of surprise to learn that it is impossible to resume operations

on an abandoned sugar estate in the tropics, except at a cost almost equal to that of starting an entirely new undertaking.

If, therefore, the figures supplied by the Board of Trade do not justify a gloomy view of the present position of the cane sugar industry in British colonies, they scarcely justify a very optimistic one. It is obvious that the capital which should be applied to the improvement of manufacturing processes and machinery is, under present circumstances, practically diverted to the mere maintenance of the cultivation. And this in the long run must be a losing game. At present the fact stands that West Indian sugar has to a large extent been driven from the home market to that of the United States. If in time it should lose that, its fate apparently is sealed.

## I.

## TOTAL PRODUCTION OF DIFFERENT KINDS OF SUGAR, 1853—87.

	1853—55.	1886—87.	Increase.
	Tons.	Tons.	Tons.
" British cane sugar.....	261,000	580,000	319,000
Foreign cane sugar.....	972,000	2,174,000	1,202,000
	1,233,000	2,754,000	1,521,000
Beetroot sugar .....	190,000	2,433,000	2,243,000
Total .....	1,423,000	5,187,000	3,764,000

"Out of a total increase of production amounting to  $3\frac{3}{4}$  million tons, no less than  $2\frac{1}{2}$  million tons, or about 60 per cent., is an increase of beet sugar, which has in fact changed its position as a factor in the production altogether, having now reached the point of being nearly equal to cane sugar, whereas at the beginning of the period it supplied only about one-eighth of the total production. Both British cane sugar and foreign cane sugar have more than doubled in the same period, and the increase in the two together amounts to  $1\frac{1}{2}$  million tons, or 40 per cent. of the total increase of  $3\frac{3}{4}$  million tons, and this increase also is obviously a very large one. It hardly compares, however, with the increase in beet sugar, which is, to a large extent, a new development altogether. Of course this table is subject to the observation that the figures in the last two or three years are specially increased by the inclusion of one or two countries formerly omitted, but a correction on this account can easily be made if thought necessary in a comparison extending over so long a period.

"This is the aspect of the progress when the beginning and end of the whole period, 1853—87, are compared. In the interval of five years, between 1880—82 and 1886—87, the figures are:—

## "INCREASE OF PRODUCTION OF DIFFERENT KINDS OF SUGAR, 1880—87.

	1880—82.	1886—87.	Increase.	1886—87 (deducting Countries included since 1884).	Increase.
	Tons.	Tons.	Tons.	Tons.	Tons.
" British cane sugar .....	419,000	580,000	161,000	531,000	112,000
Foreign cane sugar .....	1,190,000	2,174,000	975,000	1,973,000	474,000
	1,918,000	2,754,000	836,000	2,504,000	586,000
Beetroot sugar .....	1,616,000	2,433,000	787,000	2,433,000	787,000
Total.....	3,564,000	5,187,000	1,623,000	4,937,000	1,373,000

"Thus the increase in the most recent period, keeping strictly to the basis before 1884, amounts to 1,373,000 tons, of which three-sevenths may be credited to cane sugar, and four-sevenths to beet sugar. The progress of beet sugar

is thus in amount as great as ever, though the percentage increase is not quite so great as in the early part of the period since 1853. The most remarkable part of the increase of beet was, no doubt, prior to 1882.

"It will be noticed also that after about 1870 the proportion of British cane sugar in the total production was maintained steadily at about 12 per cent. until about two years ago, so that the great growth in the proportion of beet in the total production was obtained in that period at the expense of foreign cane sugar, which, in fact, declined from 54 to 39 per cent., while beet rose from 34 to 49 per cent.; but in the latest two or three years the proportion of British cane sugar in the total has been barely maintained, having fallen to 11 per cent., while foreign cane sugar has recovered a little, and beet has fallen back a little. The proportion of British cane sugar was also much higher in the earlier periods than it has since been, ranging then between 17 and 20 per cent.

"Still, at no period has there been anything but an increase in the growth of British cane sugar, though it has not kept pace with the growth of beet sugar, and in the last year or two with the growth of foreign cane sugar."

## II.

### PRODUCTION IN THE WEST INDIES.

"The average annual exports of the West Indian colonies (including British Guiana), which have always been specially interesting in this question of production, have been as follows:—

1877—79	.....	5,203,000 cwt. = 26,000 tons.
1880—82	.....	5,548,000 " = 277,000 "
1883—85	.....	6,062,000 " = 303,000 "
1886—87	.....	5,920,000 " = 296,000 "

"Since 1883—85 the West Indies have thus held their own, the difference between 303,000 tons in 1883—85 and 296,000

tons in 1886—87 being nominal only; but they have not more than held their own in these most recent years, although there is still an increase since 1880—82.

"It will be seen, moreover, from the summary in the appendix, that the production in the West Indies, exclusive of British Guiana, has not maintained itself so well on the average of years as the production in British Guiana. The production in both cases in 1887 is about the largest on record; but the average of the West Indies, excluding British Guiana, for the two years 1886—87, is brought down by an extremely low export figure in 1886."

## III.

### DISPLACEMENT OF CANE BY BEET SUGAR.

"The great increase of the production of cane sugar, again, has been an increase for consumption in extra-continental countries, principally the United States and the United Kingdom; but a certain surplus of the beet production has also overflowed into those extra-continental countries, principally the United Kingdom. This has been done, however, without diminishing the consumption of cane sugar in those countries taken altogether, although the United Kingdom in recent years has come more and more to rely largely on beet sugar, and the supply from certain cane sugar districts, particularly the West Indies, has of late rapidly diminished, these districts in turn having found a market elsewhere, particularly in the United States, for their increased production. This disposal of the overflow of beet sugar, and partial displacement of cane sugar in its proportionate importance in the market of the United Kingdom, are points of special interest . . . which may be further illustrated."

### ANNUAL IMPORTS OF SUGAR INTO THE UNITED KINGDOM, DISTINGUISHING CANE FROM BEETROOT SUGAR, &c.

	1877—78.	1882—83.	1886—88.	Increase or Decrease in 1882—83 from 1877—78.	Increase or Decrease in 1886—88 from 1882—83.
	Cwt.	Cwt.	Cwt.	Cwt.	Cwt.
Raw cane sugar from British possessions . . . .	3,450,000	5,193,000	3,292,000	— 282,000	— 1,876,000
From foreign countries . . . . .	7,100,000	8,973,000	6,585,000	+ 973,000	— 1,488,000
Total . . . . .	12,550,000	13,241,000	9,877,000	+ 691,000	— 3,364,000
Raw beetroot sugar . . . . .	3,220,000	6,891,000	7,456,000	+ 3,641,000	+ 565,000
Refined cane sugar . . . . .	215,000	125,000	718,000	— 90,000	+ 623,000
Refined beetroot sugar, i.e., refined sugar from beet-growing countries . . . . .	3,182,000	2,900,000	5,993,000	— 232,000	+ 3,093,000
Total . . . . .	19,117,000	23,127,000	24,080,000	+ 4,010,000	+ 953,000

"Thus, beetroot, though it increased largely in the five years ending 1882—83, did not gain at the expense of cane sugar, but since the date mentioned the gain has been largely at the expense of cane sugar, both in amount and proportion, and in the whole 10 years since 1878 there is a loss of cane both in amount and proportion, and a gain of beet. The imports of raw cane sugar from British possessions alone have diminished in the 10 years from nearly 5½ million cwt. to about 3½ million cwt., or a diminution of 2½ million cwt., the greater part in the last five years. At the same time the imports of raw cane sugar from foreign countries, which increased nearly 1 million cwt. in the first five years, show a falling off of about 1½ million cwt. in the subsequent five years, making a small net balance of decrease in the 10 years. Sugar from beet countries, on the other hand, has more than doubled in amount in the 10 years, the increase being from 6,350,000 cwt. raw and refined together in 1877—78, to 13,455,000 cwt. in 1886—88. There is a notable difference, moreover, in the apportionment of this increase in the two quinquennial periods. Between 1878 and 1882 the increase

of the imports from beet countries was of raw sugar, the imports of refined rather diminishing. Since 1882 the increase of the imports has only been to a small extent in raw sugar, and the increase of refined in the same period has been over 3,000,000 cwt., or as much as the total imports of refined from beet countries five years ago.

## IV.

### CHANGE OF MARKET FOR BRITISH CANE SUGAR.

"The prominent fact . . . . . is the changed amount and proportion of the imports of cane sugar from British possessions. Writing in 1884 . . . . . I pointed out that while the amount of the imports from British possessions was maintained at nearly the high figures of 1853 and subsequently, yet the *proportion* of these imports to the total had steadily declined, owing to the large growth of imports from other countries, especially beet countries. In the last five years a still greater change has taken place. The imports from British possessions have greatly diminished,

from nearly 5,000,000 cwt. in 1882, to just over 3,000,000 cwt., and the proportion, which had steadily fallen from 65 per cent. in 1853—55, to 23 per cent. in 1880—82, has since farther fallen to 13·7 per cent. only. These are not the figures of production in British possessions, which have already been dealt with, and which have not diminished, but they show that that production does not find an outlet in the market of the United Kingdom, as it formerly did, its place being there taken by beet sugar."

## V.

## INCREASE OF HOME CONSUMPTION AT DIMINISHED COST.

"The net effect, however, is that for a good many years the great increase in the quantities of sugar consumed in the United Kingdom has been accompanied by an actual decrease in the aggregate sum spent upon it by consumers in the United Kingdom. The 1,100,000 tons and upwards now consumed annually cost only in the last two years about 16,500,000*l.* annually, whereas the 900,000 to 1,000,000 tons consumed seven or eight years ago cost from 20,000,000*l.* to 24,000,000*l.* The comparison is even more striking if we go farther back. The 8,000,000 cwt. consumed 30 to 35 years ago, inclusive of duty, were as costly to the consumers of the United Kingdom as the 22,000,000 cwt. annually consumed in the last two or three years. Of course this is again subject to the above qualification as to final consumption by the people of the United Kingdom, but the reduction of price is also an important matter for the manufacturing industries in which the sugar is used."—*New Bulletin.*

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### APPLICATIONS.

2618. H. J. Haddan.—From S. T. Wellman, United States. An improved method of, or mechanism for, charging furnaces. Complete Specification. February 18.

2632. W. P. Thompson.—From A. Stehlik, Austria. Improvements in centrifugal apparatus for filtering water and other liquids. February 18.

2935. L. Vojacek. Improvements in apparatus for propelling and measuring fluids. February 24.

2961. F. E. Beeton. An improved apparatus for producing a liquid spray. February 25.

3017. H. C. Sergeant. Improvements in compressors. Complete Specification. February 25.

3186. J. Procter. Improvements in mechanical stokers for steam boiler furnaces. February 28.

3192. R. S. Baxter and G. D. Macdougland. Improvements in centrifugal machines. February 28.

3261. H. H. Lake.—From O. H. Jewell, United States. Improvements in apparatus for filtering water. Complete Specification. March 1.

3279. W. H. Skinner. Heating water or other liquids by a novel construction. March 1.

3804. Sir W. Thomson. Improvements in rheostats. March 11.

3834. R. A. Haggard. Improvements in apparatus for heating water and other liquids. March 11.

3907. R. Harvey. Improvements in and relating to evaporating apparatus. March 12.

3915. J. Schwager. Improvements in condensing apparatus for steam and other vapours. March 12.

4024. J. Foster. Improvements in and relating to evaporating and distilling apparatus. March 14.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1889.

5156. J. W. Wailes. Liquid valves for producer and other gases and air. February 26.

5496. M. W. Household. Apparatus for raising or forcing hot or vaporous liquids. March 5.

5497. M. W. Household. Apparatus for raising or forcing hot liquids. March 5.

6102. P. Cornish, jun. Means for drying or desiccating substances or materials. March 19.

6770. H. Finch and J. Mackenzie. Metallic hampers or skips for earboys, &c. March 19.

6989. E. Edwards.—From G. Lunge and L. Rohrmann. Apparatus for treating gases by liquids. March 19.

7087. J. Hill. Presses for compressing semi-fluids into solids. March 12.

8342. G. Olberg. Rotating furnaces. March 5.

10,385. R. Fölsche. An improved centrifugal machine. March 12.

18,529. W. T. Walker. Stills or apparatus for submitting liquids to the action of vapours or gases. March 19.

1890.

1476. A. J. Boulton.—From G. Schweickhardt. Improvements in tuyeres. March 5.

1877. A. Riedler. Apparatus for compressing air or gases. March 12.

## II.—FUEL, GAS, AND LIGHT.

### APPLICATIONS.

2559. H. S. Maxim and G. S. Sedgewick. Improvements relating to the carburetting or enrichment of coal and other gas and to apparatus therefor. February 17.

2611. W. W. Popplewell.—From H. Conried, United States. New or improved artificial fuel. Complete Specification. February 18.

2745. A. Moseley. Preparing chalk or limestone or gypsum to be used as a flux for improving the combustion of coal and coke in domestic and other fires, and for reducing the amount of smoke emanating therefrom. February 20.

2746. A. Moseley. Improvements in the materials and preparation of compressed coal and coke block fuel. February 20.

2927. J. Petrie. Improvements in supplying air to the flues of steam boilers for the purposes of preventing smoke and for consuming the inflammable gases therein. February 24.

2978. C. H. Mowell. Improvements in the composition of artificial or block fuel. February 25.

3081. C. Kingsford. Improvements in apparatus for inserting and withdrawing the charges from gas retorts. February 26.

3160. B. von Steenbergh. Improvements relating to the manufacture of water-gas, and to apparatus therefor. February 27.

3306. H. Ekelund. A furnace for continuous carbonising or coking. Complete Specification. March 1.

3332. B. C. Sykes and G. Blamires. Improvements in separating hydrogen gas and the light carburets of hydrogen, such as methane, from water-gas or producer-gas, or from both of them when mixed together. March 3.

3363. C. Hencken. Improvements in coke ovens. March 3.

3415. J. Armour and H. Armour. Improvements in or connected with retorts for distilling shale or other oil-yielding minerals. March 4.

3684. T. Holgate. Improvements in the method of and apparatus employed in the manufacture of coal gas and of compounds of ammonia. March 8.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

3984. J. O. O'Brien.—From W. Underwood. Manufacture of blocks of fuel from granulated or pulverised coal and other materials. March 5.

4040. E. L. Stacey. An improved firelighter, and machinery for manufacturing same. March 5.

6747. W. Bliss and others. Burning gas tar or other liquid fuel in furnaces. March 5.

6917. J. N. Flesch. Rendering petroleum less explosive, and improving its illuminating power. March 5.

6937. C. J. Langley. Artificial fuel. February 26.

7424. A. M. Chambers and T. Smith. Improvements in coke ovens, and in methods and apparatus for collecting and utilising the products of combustion therefrom. March 12.

7741. G. W. Hart. Process and apparatus for manufacturing hydrocalcium gas. March 19.

7792. J. Broad and G. C. Fowler. Improvements in nightlights, &c. March 19.

7812. G. Rose and others. Method and apparatus for the manufacture of water-gas. March 19.

8263. S. B. Darwin. Improvements in compounds for manufacturing illuminating gas, the prevention of stoppages in ascension pipes, and the deposition of naphtholine. March 19.

10,829. B. von Steenbergh. Manufacture of gas and apparatus therefor. February 26.

19,449. G. Hargreaves and others. Manufacture of gas and apparatus therefor. March 5.

1890.

1698. C. Heyer. Carburetting gases, and purifying hydrocarbons for that purpose. March 5.

## III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

### APPLICATION.

2955. H. Prople. An improved process of and apparatus for the continuous distillation of tars or mineral oils, and their products of distillation. February 24.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

6726. N. McFarlane Henderson. Retorts for the destructive distillation of shale or other oil-yielding minerals. February 26.

7634. J. Armour and H. Armour. Retorts for distilling shale or other oil-yielding minerals. March 12.

## IV.—COLOURING MATTERS AND DYES.

### APPLICATIONS.

3095. H. H. Leigh.—From R. G. Williams, United States. Improvements in the manufacture of colouring matters. February 26.

3098. H. H. Lake.—From Messrs. Wirth and Co., Agents for A. Leonhardt and Co., Germany. Improvements in the manufacture of colouring matters. February 26.

3303. B. Willecox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture of fast dyestuffs for printing and dyeing. March 1.

3397. B. Willecox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture of alpha-naphthol sulpho acids and dioxynaphtholine sulpho acids, and of dyestuffs therefrom. March 4.

3398. B. Willecox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture of mordant dyeing azo colouring matters of the triphenylmethane group. March 4.

3788. M. G. Lindemann. Improvements relating to the treatment of dyewoods and their extracts. March 10.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

4539. E. Eisenmann and A. Arche. Manufacture of picric acid. March 5.

5079. B. Willecox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture of periodides of phenols and salicylic acid. February 26.

6434. O. Imray.—From The Farbwerke vorm. Meister, Lucius, and Brünig. Production of an imide compound of fluoresceine chloride, and of colouring matters therefrom. March 5.

6777. J. E. Bedford. Manufacture of colouring matters. March 19.

6778. J. E. Bedford. Apparatus for the production of colouring matters. March 5.

7067. S. Pitt.—From L. Casella and Co. Manufacture of dyestuffs from oxyethers of alpha-naphthylamine and their sulpho acids. March 5.

7550. C. D. Abel.—From The Actiengesellschaft für Anilinfabrikation. Manufacture of green and violet colouring matters. February 26.

8264. H. H. Lake. — From Leonhardt and Co. Production of blue-black colouring matters. March 19.

12,560. S. Pitt. — From L. Casella and Co. Production of new red colouring matters. March 19.

1890.

2011. W. S. Conrad and H. T. Lilley. An improved copying ink. March 19.

## V.—TEXTILES, COTTON, WOOL, SILK, ETC.

### APPLICATIONS.

2827. A. J. Boulton. Improvements in or relating to the manufacture or treatment of textile or similar fabrics. February 21.

3261. A. A. Haigh. See Class XIX.

3749. H. Blakeley and C. Beving. A method of ornamenting textile fabrics. March 10.

3971. H. A. A. Dombraun. Improvements in cleansing wool, and apparatus therefor. March 13.

### COMPLETE SPECIFICATION ACCEPTED.

1889.

10,010. C. Pusch. Separating the wool from pieces of rabbit skins and other similar skins. March 19.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

### APPLICATIONS.

3009. S. D. Keene. Improved method or process of, and apparatus for, bleaching, dyeing, or otherwise treating fibrous materials. February 25.

3626. W. Norton and F. Hinchliffe. An improved mode of, and apparatus for, dealing with warps and hanks whilst being put through dyeing. March 7.

3651. G. T. Teasdale-Buckell. Improvements in printing in colours on paper or other material, and in the means or apparatus employed therein. March 7.

3703. W. Norton and F. Hinchliffe. An improved mode of, and apparatus for, dealing with hanks whilst being put through dyeing processes. March 8.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

5590. E. Bentz, C. Edmeston, and others. Scouring and bleaching textile fabrics, warps, and yarns formed of cotton or other vegetable fibres, and apparatus therefor. March 5.

8237. T. Parkinson. Methods of drying cotton yarns, &c. in the process of mordanting, and apparatus therefor. February 26.

9432. G. A. Greeven. Impregnating, washing, and dyeing yarn in hanks or skeins, and apparatus therefor. March 12.

## VII.—ACIDS, ALKALIS, AND SALTS.

### APPLICATIONS.

2526. The Borax Co., Lim. A new method of treating borates of lime and boracite with a view to the manufacture of borax and of other borates. Filed 17 February. Date applied for October 2, 1889, being date of application in France.

2633. J. Leith. Improvements in or appertaining to the distillation or treatment of ammonium chloride with Leblanc alkali waste or kindred substances. February 18.

3087. E. G. Lawrence. — From S. Pick, Galicia. Improvements in apparatus for evaporating liquors containing salts, and for separating such salts when rendered insoluble by evaporation of the liquors. February 26.

3220. J. Greenwood. See Class X.

3391. O. E. Pohl. Improvements in the manufacture of salt, and in apparatus and appliances employed therein. March 4.

3460. T. Michel. Improvements in the manufacture or production of carbonate of soda and hydrochloric acid from chloride of sodium. March 4.

3992. G. Horsley and A. C. Wilson. Improvements in the means or apparatus to be employed in the production of solutions containing sulphurous acid or its salts. March 14.

4095. E. Bergmann. Improvements in the manufacture or production of cyanide compounds from ferrocyanide compounds. March 15.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

7716. C. F. Hine and J. H. Noad. Process for producing cuprammonia. February 26.

16,711. E. Augé. Manufacture of soda alum. March 12.

1890.

1300. H. H. Leigh. — From T. de Brochoeki. Manufacture of anhydrous barium oxides. March 19.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

### APPLICATIONS.

2583. J. H. Bailey. Washable, glazed, or enamelled railway signal arms. Complete Specification. February 18.

2626. C. Huelser. — From J. Kemper. Process for producing opalescent glass or enamel from a glass mixture containing silico-fluorides of alkalis or compounds thereof. February 18.

2906. E. V. Caspar. Improvements in glass decoration with metallic linings. February 24.

3121. D. Rylands. Improvements in machinery for the manufacture of glass bottles or other hollow glass ware, and in the process of such manufacture. February 27.

3137. W. Ambler. An improved method and means to be used in the manufacture of glass bottles. February 27.

3138. W. Ambler. An improved method and means to be used in the manufacture of glass bottles. February 27.

3203. C. Leigh. Tinting opal glass. February 28.

3229. E. Leak and H. Aynsley. Improvements in and relating to means used in supporting biscuit and glost ware in kilns and ovens. Complete Specification. February 28.

3286. J. G. Sowerby. An improvement in the manufacture of glass. March 1.

3343. T. Fletcher, R. Crag-Brown, and W. Ure. Improvements in brick and pottery kilns. March 3.

3496. T. G. Turnbull and M. Turnbull. Improvements in or relating to glass manufacture. March 5.

4021. A. J. Boulton. — From P. Sievert, Germany. Improvements in the production of solution of alkaline silicate or water-glass, and in apparatus therefor. Complete Specification. March 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

5138. A. W. Turner and G. Tomkinson. *See* Class X.  
 7659. J. Quaglio. Process and furnace for preparation of crude glass according to Leuffgen's method, by the combined use of water-gas, coal-gas, wood-gas, oil-gas, or natural gases and generator gas. March 5.  
 8049. T. Davidson. Improvements in pressed glass dishes and their manufacture. March 19.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

2896. W. Joy. Improvements in the manufacture of cement, and in apparatus for use in the said manufacture. February 22.  
 2940. H. Benjamin. A new and useful composition of matter, which he calls "ferasphalte," to be used for roadways, sidewalks, roofing, grouting, and other purposes, including submarine works and other constructions of masonry. February 24.  
 3025. G. West. Improvements relating to plastering material or compositions. Complete Specification. February 25.  
 3070. W. Weaver. India-rubber-wood road pavements. February 26.  
 3162. J. C. Merryweather. Improvements in paving materials. February 27.  
 3184. A. Rovedino. An improved wood paving block. A similar wood paving block combined with concrete or other substance for paving. An improved paving brick of similar form and treatment as wood paving block. February 28.  
 3413. W. T. Sier. Preparing stone for enamelling and other purposes. March 4.  
 3433. W. G. Williams and S. Taylor. An irradiaut surface decoration. March 4.  
 3462. Baron A. von Solemacher. New or improved manufacture of bricks and plates or tiles. March 4.  
 4069. W. Conway. An improved brick, applicable for building purposes. March 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

5363. B. Rhodes. Non-corrosive material, suitable as a cement packing or covering to resist acids. March 5.  
 5412. T. K. Ferguson. Combination of ingredients for use as mortar, plaster, &c. February 26.  
 5919. W. S. Lea and H. M. Lynam. Manufacture and composition of refractory or fire-resisting cement or cements. March 5.  
 6874. J. N. Tata and J. Lyon. Manufacture of mosaics for floors, walls, ceilings, &c. March 5.  
 7913. S. Hindley and G. R. McKenzie. Manufacture of cement for joining wood, stone, &c. March 12.  
 20,914. A. Klapperstuck and A. H. Meyer. Fireproof ceilings and walls. March 12.

1890.

1525. I. Button, E. Peters, and J. W. Goodsell. Kilns for burning bricks, earthenware, limestone, cement, &c. March 12.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

2533. C. Thompson. The recovery of metal from sheet iron, scrap, &c. February 17.  
 2544. J. W. Chenhall. Improvements in or relating to blast or smelting furnaces having water jackets. February 17.  
 2772. E. L. Mayer and J. G. Lorrain. Improvements in or connected with the separation and recovery of gold and the treatment of ores or other matters containing gold, or with which gold is combined or associated. February 20.  
 2901. F. J. Jones. An improved method of making tubes, cylinders, and other hollow ware, of copper, its alloys, and aluminium. February 22.  
 2981. M. F. Coomes and A. W. Hyde. Improvements in the manufacture of steel. Complete Specification. February 25.  
 3154. W. A. Thoms. Improvements in the manufacture of alloys. February 27.  
 3220. J. Greenwood. Improvements in the manufacture or production of metallic sodium and of chlorine gas. February 28.  
 3245. W. D. Bohm. Improvements in the separation of gold and silver from ores or materials containing them. February 28.  
 3246. W. D. Bohm. Improvements in and apparatus for the separation of gold and silver from ores or materials containing them. February 28.  
 3275. G. Simonin. Improvements in the reduction of metallic ores. March 1.  
 3369. G. H. Cammell. Improvements in the welding of metals. March 3.  
 3409. F. W. Harbord. Improvements in the utilisation of tin-plate scrap. March 4.  
 3410. A. C. Hyde. Improvements in the process of removing tin from tin plate, and in part applicable to the preparation of pure tin. March 4.  
 3412. A. Hodgkinson, jun. Improvements in the treatment of mines and minerals containing iron, whether calcined, partly calcined, or raw, and whether mixed or unmixed, and the manufacture of the same into blocks or lumps for the better extraction of iron therefrom. March 4.  
 3440. J. L. Sehenius. Process for removing gases and foreign impurities from metals or alloys. Complete Specification. March 4.  
 3483. L. L. Burdon. Seamless compound ingot or wire. Complete Specification. March 4.  
 3532. W. Crookes. Improvements in amalgamating and extracting gold from refractory and other ores. March 5.  
 3782. L. Pszczolka. A method for obtaining uniform products from the Thomas converter, Siemens' open hearth, or other basic furnaces. Complete Specification. March 10.  
 3829. G. A. Jarvis. Improvements in plant or furnaces for the reduction of sodium or other metals. March 11.  
 4030. J. H. Darby. Improvements in the manufacture of steel or iron. March 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

4335. W. E. Everitt. Coating sheets of iron with copper or brass, and apparatus therefor. March 5.  
 5138. A. W. Turner and G. Tomkinson. Annealing furnaces. March 19.  
 7047. W. F. Jackson and W. Galbraith. Manufacture of steel. February 26.  
 8789. M. Crawford. Means for separating particles of different specific gravities, especially the separation of gold, &c. from crushed ores. February 26.  
 9905. H. A. Becker. Conversion of crude iron into malleable iron and steel, and apparatus therefor. March 12.

10,472. J. V. Johnson.—From C. Pieper. Improvements in compound steel armour plates, and in the manufacture thereof. March 12.

19,622. D. Dennes and T. K. Rose. Apparatus for extracting precious metals from their ores. March 5.

1890.

1634. G. D. Burton. Manufacture of forgings. March 5.

1641. F. W. Dähne. Calcining and refining copper ore, regulus, and precipitate, and construction of furnaces therefor. March 5.

1682. R. Heathfield. Apparatus for coating metal sheets with metals or alloys. March 5.

1888. R. C. Totten. Improvements in dies, ingots, and other castings. March 12.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### APPLICATIONS.

2687. A. W. Armstrong. The utilisation of a waste product for the means of producing electricity. February 19.

2819. C. Lütke, jun. An improved electrolytic solution for galvanic batteries. Complete Specification. February 21.

2845. E. T. Mackrill. Improvements in secondary batteries. February 21.

2945. A. M. F. Laurent-Côly and I. A. Timmis. Improvements in and relating to, and in the manufacture of, electric secondary cells. February 24.

3008. W. B. Hollingshead. Improved storage or secondary batteries. Complete Specification. February 25.

3013. C. J. Hartmann. Improvements in storage or secondary batteries. Complete Specification. February 25.

3028. A. C. Reigner. Improvements in dynamo-electric and electro-dynamic machines. February 25.

3152. W. A. Thoms. Improvements in the manufacture of electrical conductors. February 27.

3153. W. A. Thoms. An improved mode of manufacturing electrical conductors. February 27.

3271. C. N. Russell and R. A. Scott. Improvements in dynamo-electric machines. March 1.

3322. F. Keep.—From T. and S. Morrin, Limited, New Zealand. An improved voltaic battery. March 3.

3373. M. Sappey. Improvements connected with the charging of electrical accumulators or secondary batteries. March 3.

3374. G. E. B. Pritchett. Improvements in electric accumulators or secondary batteries. March 3.

3439. S. C. C. Currie. Improvements in secondary or storage batteries. Complete Specification. March 4.

3455. H. H. Lake.—From T. Ewing, United States. Improvements in and relating to electric secondary batteries or accumulators. Complete Specification. March 4.

3572. Sir C. S. Forbes, Bart. Improvements in primary batteries. March 6.

3697. J. Anderson. Improvements in galvanic cells and batteries. March 8.

3717. L. Weigert. An improved electrolytic solution for galvanic batteries. Complete Specification. March 8.

3731. The Mining and General Electric Lamp Co., Lim., and D. G. FitzGerald. Improvements in or connected with the positive elements (negative electrodes in charging) of secondary batteries, which elements are applicable also as cathodes in electrolysis. March 8.

3924. H. H. Lake.—From The Crosby Electric Co., United States. Improvements in electric batteries. Complete Specification. March 12.

3967. J. S. Stevenson. Improvements in or connected with the manufacture of secondary battery elements. March 13.

4087. H. T. Cheswright. Improvements in secondary voltaic batteries. March 15.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

4871. H. A. Seegall. Electrolytic process of obtaining copper, zinc, and tin. February 26.

6745. M. Kiliani. Method and means for electrolysis of substances in a state of fusion. February 26.

7428. C. Pollak. Electric accumulators and plates or electrodes therefor. March 12.

14,148. J. Kümme. Manufacturing pipes, tubes, and other articles of metal by galvanic deposits. March 12.

20,217. F. Marx. Manufacturing metallic electrodes for galvanic batteries. March 12.

1890.

1094. H. H. Lake.—From T. Ewing. Secondary or storage batteries. February 26.

1110. C. A. Hitchcock.—From W. Burnley. Galvanic batteries. February 26.

1495. H. H. Lake.—From G. A. Johnson. Storage batteries or accumulators. March 5.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

### APPLICATIONS.

2864. W. Young. Improvements in purifying or treating paraffin wax, and in apparatus therefor. February 22.

3303. M. Williams. Improvements in the manufacture of soft soap. March 5.

3601. R. C. Scott. Improvements in or appertaining to the manufacture or shaping of soap. March 6.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

11,383. C. Lahnson and C. Feuerlein. Extracting pure neutral grease from wool or the like. March 12.

1890.

1659. P. Plisson. Manufacture of lubricating grease, and apparatus therefor. March 5.

## XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

### APPLICATIONS.

2539. N. B. Dennys. An improvement in preservative and anti-fouling compositions for ships' bottoms, &c. February 17.

2682. J. Sloan and E. W. Bell. Improvements in anti-fouling or preservative paints or compositions. February 19.

2727. J. Horne. Improved manufacture of hand-clean white and coloured crayons and materials for marking and colouring surfaces. February 20.

2808. W. Noad. Improvements in the manufacture of white lead. February 21.

3786. G. Larrony. Improvements in or relating to the manufacture of litharge and red lead. March 10.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

6815. R. W. E. MacIvor and others. Production of white lead or carbonate of lead. February 26.

7156. J. Macfarlane. Obtaining yellow pigments. March 5.

9412. M. Williams and J. Aseough. Manufacture of blue colouring matter for laundry, bleaching, and other purposes. March 5.

9565. H. Noerdlinger. Manufacture of oil varnish. February 26.

16,706. P. Bronner. Manufacture of white lead. March 19.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

## APPLICATION.

3295. P. Houston and C. Beakbaue. Improvements in the manufacture or production of tannage or tanning liquors. March 1.

## COMPLETE SPECIFICATIONS ACCEPTED.

1890.

556. G. Rothel. An improved glue or cement. March 19.

1482. W. P. Thompson.—From F. G. Hermann. Apparatus for removing the hair from skins. March 5.

## XVI.—SUGARS, STARCHES, GUMS, Etc.

## APPLICATIONS.

3030. A. Weisz. Improvements in the manufacture of starch. February 25.

3240. A. A. Brehier and B. G. Talbot. Manufacture of artificial tartaric acids by means of cellulose, saccharine, or amylaceous substances. February 28.

3589. C. Steffen. Improved process for obtaining the entire crystallisable sugar contained in more or less pure saccharine solutions, juices of plants and the like, by employing the same for washing crystalline sugar mass in special manner before the said saccharine solutions are subjected to a novel method of boiling same. Complete Specification. March 6.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

7517. G. Adant. Apparatus for the manufacture of sugar. March 12.

1890.

1282. C. D. Abel.—From Messrs. Pfeifer and Langen. Treatment of sugar crystals or grains for facilitating the purifying thereof. March 5.

2197. W. P. Thompson.—From K. Korenar and F. Zwicker. A new adhesive cement, and process of manufacturing same. March 19.

## XVII.—BREWING, WINES, SPIRITS, Etc.

## APPLICATIONS.

2958. J. Stevenson.—From E. Riglet, France. The production of alcoholic beverages and alcohol without the employment of cereals. February 24.

2990. H. S. G. Stephenson. Improvements in apparatus for generating and supplying carbonic acid gas to vessels containing fermented liquor. February 25.

3579. C. Hof.—From L. Rüksam, Bavaria. Improvements relating to the production of malt. March 6.

3606. E. Carez and La Société Generale de Maltosé. An improved method of saccharification of amylaceous materials. March 6.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

3707. C. R. C. Tielborne, A. Darley, and M. F. Pureell. Method and appliances for the collection and utilisation of the carbonic acid and other products given off during the process of all fermentations. March 12.

3981. G. Reininghaus. Preparation of malt. March 5.

6918. C. R. Bonne. Manufacture of German yeast. February 26.

8313. L. A. Enzinger. Apparatus for sterilising fermented alcoholic liquors. February 26.

8839. C. Huelser.—From J. Kuntze. Apparatus for pneumatic malting. March 19.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

## APPLICATIONS.

*A.—Chemistry of Foods.*

2620. F. Grognet. A new or improved method for preserving meat, fish, and the like. February 18.

2742. J. Y. Johnson.—From C. Risk, West Indies. Improvements in curing cocoa and the like, and in the means and apparatus employed therefor. February 20.

3856. E. Leconte. Improvements in the treatment or regeneration of yeast to be used in the process of bread-making, and in the preparation of paste and dough for pastrycooks and biscuit-bakers. March 11.

3995. G. Dosmond and F. Rozes. An improved process and apparatus for preserving meat and other alimentary substances. March 14.

4102. A. A. Brehier. Improvements in the preservation of meat and other articles of food, such as poultry, game, fish, eggs, cheese, fruits, vegetables, &c. March 15.

*B.—Sanitary Chemistry.*

2563. S. F. Milligan and R. Barklie. Apparatus for destroying deleterious emanations from sewers. February 18.

3062. F. L. H. Daneshell. Improvements in the treatment of sewage or other liquids having matters in suspension, and in means or apparatus employed therein. February 26.

3312. W. E. Adeney and W. K. Parry. Improvements in the purification of sewage and other waste liquors containing organic matters. March 1.

*C.—Disinfectants.*

3134. I. S. McDougall and J. T. McDougall. Improvements in compounds for washing or dipping sheep, cattle and horses for the extermination of insects or parasites. February 27.

3628. F. Bale and C. Sims. Improvements in the manufacture and production of hydroxyl and peroxide of hydrogen or oxide of water, and in the apparatus employed therein. March 7.

## COMPLETE SPECIFICATIONS ACCEPTED.

*A.—Chemistry of Foods.*

1889.

3172. E. Sonstadt. Processes and apparatus for preparation of an extract of coffee, and utilisation of the by-products. March 5.

1890.

1326. A. Schmidt-Mulheim. Method and apparatus for production and preservation of sterilised milk. March 5.

1328. J. T. Appleberg. Apparatus for and method of preserving and purifying milk. March 12.

*B.—Sanitary Chemistry.*

1889.

5753. B. Jagger, H. B. Jagger, and A. Turley. Means for purifying sewage and other waters, and for deodorising and utilising the solids and excreta. March 12.

8088. C. H. Beloe and F. Candy. Purification and filtration of sewage and other foul liquids. March 12.

*C.—Disinfectants.*

1889.

19,309. G. T. Moody and F. W. Streatfield. Producing and liberating aerial or gaseous disinfectants. March 19.

**XIX.—PAPER, PASTEBOARD, Etc.**

*APPLICATIONS.*

2698. W. B. Kemshead. Improvements in the manufacture of paper and like textile fabrics. February 19.

2832. E. Applegarth. Improvements relating to the treatment of straw, esparto grass, and other fibrous materials, and to compounds therefor. February 21.

3264. A. H. Haigh. Improved waterproof paper and textile fabrics. March 1.

3593. S. W. Marchant, jun. Improvements in the manufacture of paper, and in apparatus therefor. March 6.

*COMPLETE SPECIFICATIONS ACCEPTED.*

1889.

17,496. E. A. Blumel. Covering various articles with xylonite or celluloid. March 19.

19,638. R. Hannan. Toilet or sanitary paper. March 12.

1890.

682. O. Imray.—From the Celluloid Manufacturing Co. Collar, cuff, and front, with waterproof body, and coverings having a coating of pyroxyline varnish. March 12.

683. O. Imray.—From the Celluloid Manufacturing Co. Waterproof collar, cuff, and front, composed partly of vegetable parchment. March 12.

1514. F. C. Alkier. Extracting substances dissolved in the waste-water of paper manufacture. March 5.

**XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.**

*COMPLETE SPECIFICATION ACCEPTED.*

1889.

7391. J. F. von Mering. Production of a substance to be called "chloralformamide" or "chloralamide." February 26.

**XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.**

*APPLICATIONS.*

3393. E. W. Foxlee. An improved flexible film as a support for photographic negatives and positives. March 4.

3958. J. W. Clarke. A new or improved process for the reproduction of photographs or other devices or purposes, and in readily reproducing same. March 13.

*COMPLETE SPECIFICATION ACCEPTED.*

1889.

8085. H. W. Jones. Production of developers for photographic use. March 12.

**XXII.—EXPLOSIVES, MATCHES, Etc.**

*APPLICATIONS.*

2547. J. Y. Johnson.—From C. Pieper, Germany. Improvements in the manufacture of gunpowder from nitro-cellulose. February 17.

2769. H. A. Schlund. Improvements in percussion fuses. February 20.

2883. D. D. Eason. Improvements in fuses. February 22.

2960. W. D. Borland. Improvements in nitro-compound powders for ballistic purposes. February 25.

2993. J. Beswick. Improvements in or appertaining to blasting and other operations where gunpowder is not used. February 25.

3176. C. F. Martin. An improvement in matches. February 28.

3475. J. C. Bull. Improvements in percussion fuses. March 4.

3604. F. E. D. Acland. Improvements relating to time and percussion fuses. March 6.

3819. E. C. Mance. Improvements in signal rockets. March 11.

3852. H. H. Lake.—From S. H. Emmens, United States. Improvements in explosives. March 11.

3865. M. E. Steedman. An improved lucifer match. March 12.

*COMPLETE SPECIFICATIONS ACCEPTED.*

1889.

3761. H. C. L. Holden. Electric tubes and fuses for firing ordnance and exploding torpedoes, mines, &c. March 12.

4539. E. Eisenmann and A. Arche. Manufacture of picric acid. March 5.

5208. C. R. E. Bell. Manufacture of matches, and apparatus therefor. March 5.

6185. H. T. Arbuthnot and G. Hookham. Percussion fuses for explosive shells. March 12.

6595. L. Cobbaert. A machine for the continuous manufacture and boxing of matches. March 12.

# THE JOURNAL OF THE Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 4.—VOL. IX.]

APRIL 30, 1890.

[Non-Members 30/- per annum; Members  
21/- per Set of extra or back numbers  
Single Copies (Members only) 2/6.]

## The Society of Chemical Industry.

### Past Presidents:

Sir H. E. Roseoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond	1888—1889.

## COUNCIL FOR YEAR ENDING JULY, 1890.

*President: Sir Lowthian Bell, Bart., F.R.S.*

### Vice-Presidents:

R. Forbes Carpenter.	S. H. Johnson.
<i>Prof. F. Clowes, D.Sc.</i>	Ludwig Mond.
<i>Sir J. Neilson Cuthbertson.</i>	Dr. Hugo Müller, F.R.S.
Prof. James Dewar, F.R.S.	Dr. W. H. Perkin, F.R.S.
Jas. Duncan.	Dr. Edw. Schunck, F.R.S.
<i>Dr. John Evans, F.R.S.</i>	<i>Prof. W. A. Tilden, F.R.S.</i>

### Ordinary Members of Council:

L. Archbutt.	B. E. R. Newlands.
S. B. Boulton.	Jno. Pattinson.
Jno. Broek.	Jno. Spiller.
Jno. Calderwood.	E. C. C. Stanford.
<i>Alexander M. Chance.</i>	J. C. Stevenson, M.P.
<i>A. E. Fletcher.</i>	A. Norman Tate.

With the Chairmen and Secretaries of Sections.

### Honorary Treasurer:

*E. Rider Cook*, East London Soapworks, Bow, E.

### Honorary Foreign Secretary:

*Dr. Ferdinand Hurter.*

*General Secretary: Charles G. Cresswell.*

## NOTICES.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those Members of Council whose names are placed in italics in the annexed list will retire from their respective offices at the forthcoming Annual General Meeting.

Mr. E. Rider Cook has been nominated to the offices of President and Treasurer; and Sir Lowthian Bell, Bart., F.R.S., has been nominated Vice-President under Rule II.

Mr. David Howard, Mr. B. E. R. Newlands, and Mr. J. C. Stevenson, M.P., have been nominated Vice-Presidents under Rule 8; and Mr. R. R. Tatlock and Mr. T. W. Stuart have been nominated Ordinary Members of Council under Rule 17, in the place of Mr. B. E. R. Newlands and Mr. J. C. Stevenson, M.P., nominated Vice-Presidents.

The Foreign Secretary has been nominated for re-election.

Members are hereby invited to nominate fit and proper persons to fill four vacancies among the Ordinary Members of Council under Rule 18. Special nomination forms for this purpose can be obtained from the General Secretary upon application.

*Extract from Rule 18:*—"No such nomination shall be valid unless it be signed by at least ten members of the Society who are not in arrear with their subscriptions, nor unless it be received by the General Secretary, at the Society's office, at least one month before the date of the commencement of the Annual General Meeting, to the election to take place at which it refers. Nor shall any such nomination be valid if the person nominated be ineligible for election under Rules 12 or 15. No member shall sign more than one nomination form."

#### ANNUAL GENERAL MEETING.

Notice is hereby given that the next Annual General Meeting will be held in Nottingham on Wednesday, Thursday, and Friday, the 9th, 10th, and 11th of July next. Detailed arrangements and the programme of proceedings will appear as soon as complete. Tickets of membership will be issued in time for the meeting, and will form, as heretofore, vouchers for visits to works and excursions.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

#### LIST OF MEMBERS ELECTED, 23rd APRIL, 1890.

- Allen, Wm. N., 2, Chesnut Street, Philadelphia, Pa., U.S.A., chemical manufacturer.
- Bentz, Ernest, 147, Bishop Street, Alexandra Park, Manchester, lecturer on dyeing.
- Blakey, A. J., Dudridge Mills, Stroud, Gloucestershire, foreman dyer.
- Craig, Saml. E., 110, Cannon Street, London, E.C., colliery representative.
- Fleck, Hermann, 108, Rittenhouse Street, Germantown, Philadelphia, Pa., U.S.A., chemical student.
- Frost, Howard V. (Ph.D.), Polytechnic Inst., Brooklyn, N.Y., U.S.A., professor of chemistry.
- Hoskins, A. Percy, 19, Ashness Road, New Wandsworth, S.W., analytical chemist.
- Kerr, Saml. T., c/o Alex. Kerr Bros. and Co., Philadelphia, Pa., salt manufacturer.
- Lang, Jas. G., 5, Viewfield Terrace, Hillhead, Glasgow, analytical chemist.
- McCulloch, Norman, 7, Melrose Street, Glasgow, analytical chemist.
- McDougall, Jas. T., Dunolly, Morden Road, Blackheath, S.E., manufacturing chemist.
- McFarlane, W. W., 110, Oxford Street, Philadelphia, Pa., U.S.A., dye works superintendent.
- Marvin, Chas., Grosvenor House, Plumstead Common, Kent, author.
- Mayer, Nelson B., 945, North 8th Street, Philadelphia, Pa., U.S.A., chemical student.
- Morris, Herbert N., Littondale, Manley Road, Manchester, chemical student.
- Porter, Herbert, Pleasley Meadows, near Mansfield, Notts, wool spinning manager.
- Pullman, Arthur, "Stalheim," Godalming, Surrey, leather manufacturer.
- Pullman, Edw. E., Westbrook Mills, Godalming, Surrey, leather manufacturer.
- Pullman, Wm. R., Hermitage, Godalming, Surrey, leather manufacturer.
- Reid, J. Keith, Buckingham, Prov. of Quebec, Canada, mining agent.
- Rogers, Harry, 5, Stoke Newington Common, London, N., secretary to Patent Stone Co.
- Smith, Henry H., Royal Laboratory, Woolwich Arsenal, S.E., analytical chemist.
- Strawson, Geo. Fred., Newbury, Berks, chemical manufacturer.
- Studer, Simon J., Phoenix Chemical Works, Bradford, Manchester, chemist.
- Welsh, Thos. L., 51, St. Vincent Crescent, Glasgow, chemical student.
- Wetter, Jasper, 433, Strand, London, W.C., patent agent.
- Wood, Ebenezer, Stephenson Street, Canning Town, E., manufacturing chemist.
- Wyatt, Francis (Ph.D.), 24, Park Place, New York, U.S.A., consulting chemist.

#### CHANGES OF ADDRESS.

- Bahington, P., l/o Rotherham; Astyra Mining Co., Dardanelles, via Constantinople.
- Bayley, Thos., l/o Clonskeagh; 3, Herbert Avenue, Merrion, co. Dublin.

Bell, J. Ralston, 1/o Doneaster; 27, Lansdowne Creseent, Glasgow.

Branson, F. W., Journals to 24, Mount Preston, Leeds.

Burrows, Edw., Journals to Belle Vue Road, Low Fell, Gateshead-on-Tyne.

Collins, C. Spenceer, 1/o Manchester; 16, Albert Place, Leith Walk, Edinburgh.

Collins, H. S., 1/o Thames Street; e/o Langton and Co., 38, Wilson Street, Finsbury, E.C.

Donald, W. J. A., Journals to Castle Park, Irvine, N.B.

Elborne, Wm., 1/o Manchester; 4, Willis Road, Petersfield, Cambridge.

Fraser, W. J., Journals to 98, Commereial Road East, London, E.

Grundtvig, C. H. W., Journals to e/o Lake Copais Co., Thebes, Greecee.

Jenkins, Thos., 1/o Wales; Laboratorio, Minas de Rio Tinto, Spain.

Kent, W. H., 1/o Wokingham Road; The Lodge, Bulmershe Road, Reading.

Lake, G., jun., 1/o Manchester; 6, Turn Lee Road, Glossop, Derbyshire.

Laws, J. P., Journals to 32, Holborn Viaduct, London, E.C.

Leigh, Cecil, 1/o Seaham; Adderley Park Rolling Mills, Birmingham.

Luck, E., 1/o 70; 122, Stamford Street, London, S.E.

Luck, H. C., 1/o 70; 122, Stamford Street, London, S.E.

Marshall, Dr. T. R., 1/o Edinburgh; Mason College, Birmingham.

Mitting, E. K., 1/o North Water Street; 423, Superior Street, Chicago, Ill., U.S.A.

Pitt, Theo., 1/o 16; 12, Coleman Street, E.C.

Reid, W. G., 1/o Galashiels; 3, Findhorn Place, Edinburgh.

Renaut, F. W., 1/o Fulham; 19, Great George Street, Westminster, S.W.; and Journals to 29, Craster Road, Elm Park, Brixton, S.W.

Robinson, H. H., 1/o Canton; Imperial College, Hankow, China.

Smith, H. H., Journals to Wilton House, Vicarage Park, Plumstead, S.E.

Tervet, R., 1/o Glasgow; 41, Morpeth Road, South Hackney, E.

Tothill, M. A. L., 1/o Riebeck Square; e/o Castle Chemical Co., Cape Town, South Africa.

Wills, G. S. V., 1/o Tulse Hill; Southwood, Croham Road, South Croydon.

Wilson, C. J., 1/o Gordon Square; 19, Little Queen Street, Westminster, S.W.

## London Section.

*Hon. Local Sec. and Treasurer: Thos. Tyrer, Battersea, S.W.*

The names in Italics are those of members of Committee who retire at the end of the current Session.

The following have been elected to fill the vacancies and will take office in July next:—*Chairman: T. Tyrer; Secretary: T. W. B. Mumford; Committee: J. Dewar, A. G. Green, C. W. Heaton, D. Howard, W. S. Squire, T. E. Thorpe.*

### SESSION 1889-90.

1890.

May 5th:—Mr. M. L. Grillin. "Moisture in Paper Pulp" and other communications.

June 2nd:—Dr. W. S. Squire. "The Artificial Production of Cold theoretically and practically considered."

July:—Annual General Meeting in Nottingham.

Mr. Wm. Webster's paper on "The Electrical Treatment of Sewage" is postponed.

*Meeting held Monday, March 31st, 1890.*

MR. DAVID HOWARD IN THE CHAIR.

### NOTE ON A MACHINE FOR A METHODICAL SEPARATION OF SOLIDS AND LIQUIDS.

BY W. S. SQUIRE, PH.D.

SOME time ago I had occasion to design a machine for the separation of solid from liquid matters in such a way that the solid matter should be completely washed out and exhausted of its soluble constituents, while, on the other hand, this should be accomplished with the least possible dilution of the liquid. As this machine worked very well in practice, I thought a description of it might interest the members of the London Section of this Society. It is, however, a machine which is not of universal applicability. It will not, for example, deal with freshly-precipitated sulphate of barium, or anything of that kind, but is intended rather for dealing with vegetable matters, such as beetroot, brewers' grains, and substances of that description.

This machine consists of a series of cylinders, usually four in number, constructed of perforated metal, or of wire gauze, or of cloth stretched on suitable frames. These cylinders revolve horizontally, but slightly inclined over troughs placed underneath them to receive the liquid which passes through, while the solid matter is discharged at the lower end of the cylinders into vessels placed so as to receive it. Each of these vessels is provided with an agitator to mix up the solid matter with any liquid that may be added to it, and is also provided with a pump in order to pump away the mixture so made.

The mixture of solid and liquid matter to be treated is admitted in a stream into the upper end of cylinder No. 1. The liquid passes through into the trough below, while the solid matter is expelled at the lower end of the cylinder into the vessel placed to receive it. It is here mixed with the liquor flowing from the trough placed under cylinder No. 3, and the mixture is pumped into cylinder No. 2. The liquid which passes through into the trough below is either added to that coming from cylinder No. 1 or it is

## Death.

J. B. Hutcheson, of Glasgow University, at Dunoon, N.B. April 15th.

used to dilute the original mixture before it is admitted to cylinder No. 1, or it may be used for treating fresh solid matter, the soluble constituents of which it is desired to extract. The solid matter expelled from the lower end of cylinder No. 2 is in like manner mixed with the liquid coming from the trough under cylinder No. 4, and is then pumped into cylinder No. 3. The solid matter expelled from this cylinder is mixed with water or other menstruum and pumped into cylinder No. 4, from which it is finally expelled, washed out and exhausted. In this way the solid

matter travels successively from cylinder to cylinder, encountering on its course liquid always more and more dilute whilst the liquid travels in the opposite direction, encountering on its course matter more and more charged with soluble matter. If the exhaustion is not complete a larger number of cylinders may be used.

Fig. 1 is a side elevation of the apparatus. Fig. 2 is a plan in which two of the four cylinders are shown in view and two in section. Fig. 3 is an elevation of the upper ends of the four cylinders, and Fig. 4 is an elevation of the lower ends

Fig. 1.

Fig. 2.

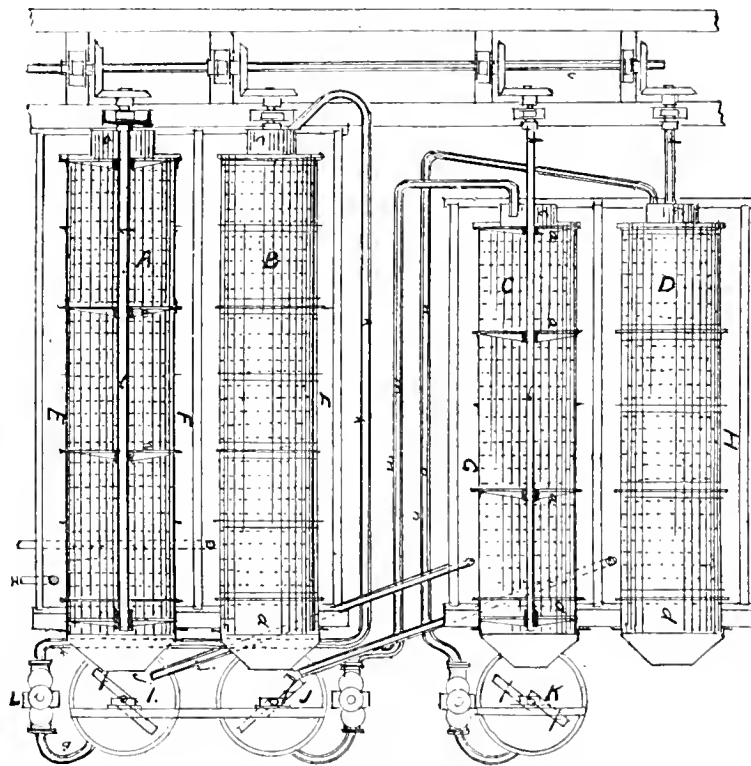

Fig. 3.

of the four cylinders where the solid matter is discharged. A B C D are the four perforated cylinders, E F G H are the four troughs into which the liquid falls through the perforations of the cylinders. (In this case there are only two troughs, but each is divided into two by a division in the

centre so as practically to form four troughs.) I J K are the vessels into which the solid matter is discharged from the mouths of the revolving cylinders, and L M N are the pumps by means of which the mixture of solid and liquid matters are pumped into the successive cylinders.

Fig. 4.

The perforated cylinders may be made in one piece, but I prefer to build them up of short perforated drums bolted to flat spoked wheels *aa* (Fig. 2) keyed on to the driving shafts *bb*. The upper ends of the cylinders are closed by means of a plate with an orifice in the centre furnished with a short drum (*c*) not perforated, which serves for the introduction of the mixture of solid and liquid matters by means of pipes entering these drums by the side of the driving shafts. The other end of the cylinders consists of a drum of metal *d* of the same diameter as the cylinder, but not perforated, furnished with spokes, and keyed on to the driving shaft. Through these drums the solid matters are discharged. These drums run on small wheels, *ee* (Figs 1 and 4), which support the lower end of the cylinder.

The vessels I J K into which the solid matter is discharged are furnished with agitators *f f* which stir up and mix the discharged solid matter with any liquid which may run into these vessels. The pumps L M N are lift and force pumps connected by the pipes *g g* with the receiving vessels, and are intended to pump the mixture of solid and liquid matters into the cylinders. Both pumps and agitators are driven by means of an overhead shaft *h* furnished with eccentrics and bevil wheels for that purpose. The cylinders are driven by means of a main shaft *i* by means of mitre wheels keyed on to the main shaft and the driving shafts of the cylinders.

The course of the operation is as follows :—The mixture of solid and liquid matters is introduced into the cylinder A through the small drum *c*. As the cylinder revolves the liquid runs through the perforations of the cylinder into the trough E placed below it, and is drawn off by the pipe *r*. The solid matter in consequence of the inclined position of the cylinder gradually makes its way to the lower end, where it is discharged. As the solid matter has been thoroughly rolled over and puddled in its course from the upper to the lower end of the cylinder, it is deprived of most of the liquid matter. It is discharged into the vessel I, where it meets the liquid matter flowing from the trough G placed below the cylinder C through the pipe *j*, and the mixture so formed is pumped by the pump L through the pipe *k* into the cylinder B. The liquid which runs through into the trough F may be mixed with the liquid which falls into the first trough E, or it may be used for treating a fresh quantity of solid matter before it is introduced into the cylinder A. The solid matter which is discharged into the vessel J is mixed with the liquid from the trough H under the cylinder D through the pipe *l*, and the resulting mixture is then pumped by means of the pump M through the pipe *m* into the cylinder C. The liquid which passes through this cylinder falls into the trough G and flows through the pipe *j* to the vessel I. The solid matter is discharged into the vessel K, where it is mixed with water or other menstruum

used to exhaust and wash out the solid matter. This mixture is then pumped by the pump N through the pipe *n* into the cylinder D. The liquid which runs through the cylinder D falls into the trough H and flows through the pipe *l* to the vessel J. The solid matter is discharged from this last cylinder D, washed out, and exhausted of its soluble matter.

It will be noticed that the solid matter travels progressively from A to B, from B to C, and from C to D, while the liquid travels in the opposite direction, from D to C, from C to B, and if used as the solvent of the soluble matters of any fresh solid matters from B to A. The process is, therefore, thoroughly methodical and continuous, and while on the one hand a very concentrated solution of the soluble matters is obtained, on the other hand the solid matter is obtained thoroughly exhausted of its soluble constituents.

Although I prefer to use cylinders for the purpose indicated, the inclined revolving perforated chambers may be of hexagonal, octagonal, or polygonal section.

When the apparatus is at work the separated liquor is discharged in a constant stream, while the exhausted solid matter falls continuously from the mouth of the last cylinder.

#### DISCUSSION.

The CHAIRMAN said that chemical engineering was a subject of primary interest to this Society, and, recognising the importance of the subject, the Society was always glad to welcome the suggestions of its engineering members. In the subject of the paper before them, they had one of those valuable suggestions which would be found applicable to a large number of bodies, and whose importance was enhanced by its suggestiveness of even further applications than those referred to by the inventor. There was one point of general practical interest which occurred to him :—How to get the maximum of exhaustive effect with a minimum of wash-water or solvent. The problem presented itself differently in different industries, whether in exhausting black ash or in making the tincture of a valuable drug. The apparatus described by Dr. Squire seemed to him to be a happy solution of at least one form of the problem.

## WOOL-FAT AND PROCESSES OF OBTAINING IT, WITH SPECIAL RELATION TO WOOL-WASHING.

BY H. W. LANGBECK.

WOOL-FAT mixed with water, in relation to medicine, has first been mentioned by Dioscorides, a Greek physician and author, living in the first century A.D. Such mixture of wool-fat and water was then called "Oesypus" (Οἶσυπος), and it retained this name for many centuries. Plinius also gives a description of Oesypus and how it is to be prepared. The Greek text and its translation into English is as follows:—

Κεφ. πδ'.—Περὶ Οἶσυπου.

Οἶσυπος δὲ λέγεται τὸ ἐκ τῶν οἰσυπρῶν ἐρίων λίπος· ὃ κατασκευάζεται οὕτως· λαβὼν ἕρια μαλακὰ οἰσυπρὰ ἐκπλυνον μὴ ἐστρουθισμένα θερμῷ ὕδατι, ἅμα ἐκθλίβων πᾶσαν τὴν ῥυπαρίαν, ἣν βαλὼν εἰς κρατῆρα πλατύστομον καὶ ἐπιχέας ὕδωρ ἀνάχει ἀρυτήρι ταράσσω βαγδαίως, ἕως ἂν ἀφρίσῃ· ἡ ξύλλω ἀνατάρασσε εὐτόνως, μέχρις ἂν ὁ πολὺς ἀφρὸς καὶ ῥυπαρὸς συλλεγῇ. ἔτα κατάρβαινε θαλάσῃ, καὶ ὅτε καταστῇ, τὸ ἐπινυχόμενον λίπος, ἀναλάμβανε εἰς ἕτερον κεραμεῦον ἀγγεῖον, ἐπιχέας τε ὕδωρ εἰς τὸν κρατῆρα, πάλιν τάρασσε καὶ κατάρβαινε τῇ θαλάσῃ τὸν ἀφρὸν, καὶ ἀναλάμβανε· καὶ τὸ αὐτὸ ποιεῖ, ἄχρις ἂν μηκέτι ἀφρὸς ἐφίστηται, δαπανηθέντος τοῦ λίπους. Τὸν μόντον ἀνηρημένον οἶσυπον τῇ χειρὶ μαλάσας, παραχρῆμα ἀναφοῦ, εἴ τινα ἔχει ἀκαθαρσίαν, στραγγίζον τὸ πρῶτον ὕδωρ καὶ ἄλλο ἐπιχέων καὶ κινῶν τῇ χειρὶ, ἄχρις ἂν προσαγόμενος τῇ γλώττῃ μὴ δάκνῃ, ποσὼς δὲ στύφῃ, λιπαρὸς καὶ καθαρὸς καὶ λευκὸς φανῇ· οὕτω δὲ ἀποτίθεο εἰς ἀγγεῖον κεραμεῖον· ἐν ἡλίῳ δὲ θερμῷ γινέσθω πάντα· ἔνιοι δὲ διηθήσαντες τὸ λίπος πλύνουσιν ἐν ὕδατι ψυχρῷ, ταῖς χερσὶν ἀνατρίβοντες, ὡς τὴν κηρωτὴν αἱ γυναῖκες· γίνεται δὲ ὁ τοιοῦτος λευκότερος· οἱ δὲ πλύναντες τὰ ἕρια καὶ ἐκθλίψαντες τὸν ῥύπον, ἔψουσιν μεθ' ὕδατος ἐν λέβητι πυρὶ κούφῳ, καὶ τὸ ἐπιστάμενον λίπος ἀφαιρούντες πλύνουσιν ὕδατι, ὥσπερ εἴρηται· καὶ διυλίσαντες εἰς λοπάδιον κεραμεῖον, ἔχον ὕδωρ θερμὸν, λυφὲ τέ ῥάκει περιτωμάσαντες, τίθεασιν ἐν ἡλίῳ, μέχρις ἂν αὐτάρκως παχὺς καὶ λευκὸς γίνηται· ἔνιοι δὲ διὰ δύο ἡμερῶν ἀποχέοντες τὸ πρῶτον ὕδωρ, ἄλλο ἐπιχέουσιν· ἔστι δὲ βελτίον ὁ ἀστρούθιστος καὶ λεῖος, ὅζων ἐρίων οἰσυπρῶν, ἀνατριβόμενός τε μεθ' ὕδατος ψυχροῦ ἐν μνάκι, καὶ λευκαίνόμενος, καὶ οὐδὲν ἔχων ἐν ἑαυτῷ σκληρὸν ἢ συνεστηκὸς, ὥσπερ ὁ δολιζόμενος κηρωτῇ ἢ στέατι. Δύναμιν δ' ἔχει θερμαντικὴν, πληρωτικὴν ἐλλκῶν, μαλακτικὴν, μάλιστα τῶν περὶ δακτύλιον καὶ ὑστέραν σὺν μελιωτῇ καὶ βουτύρῳ.

“CHAP. 84.—CONCERNING WOOL-FAT.

“Wool-fat is called the grease out of the filth of new shorn wool. You will prepare it in this manner: Having taken sweet newly shorn wool, not treated with soap wort, wash it in hot water, at the same time squeezing out all the filth; having put this into a wide-mouthed vessel pour water over it, and agitating it violently until froth is formed, pour it out again of the vessel; or agitate it vigorously with a stick until much scum and filth collects; thereupon sprinkle sea water over it, and when the fat swimming on the top has set put it into another earthenware vessel; pour more water into the tub, stir it up again, sprinkle the froth with sea water and take it out again, and do so until after the fat has been exhausted, no more froth gathers. Smooth the collected wool-fat with the hand, and if there is any filth remove it forthwith, squeezing out the first water and pouring on fresh and agitating it with the hand until applied to the tongue, it does not bite but has an astringent taste and looks brilliant and pure and white. In this condition store it away in an earthenware vessel. But all must be made in hot sunshine. Some treat the fat by washing it in cold water, rubbing it with the hands as women (do with) wax, thus it is rendered whiter. Others, after washing the wool and squeezing out the grease, boil it together with water in a cauldron over a slow fire, and having gathered the fat which swims on the top they wash it with water, as has been said, and straining it into an earthenware

dish containing hot water, and covering it with a linen cloth they place it into the sun until it becomes sufficiently thick and white. Some pour off the first water after a lapse of two days, and pour on fresh. Better is that which has not been treated with soap wort and is smooth, smelling of the oily wool, washed with cold water in a shallow dish, and having been bleached and containing in itself no hard or solid (particles), as for instance that which is adulterated with wax or tallow. It possesses a power to close up wounds, to soften especially with melilot and butter.”

Nicolas Culpeper, gentleman student in physick and astrology, in his *Pharmacopœia Londinensis*, published 1653, gives also a recipe for making Oesypus:—

“*The Manner of Preparing Oesypus.*—Take of wool uncleaned which was taken off from the neck, ribs, and shoulder pits of the sheep, put it into warm water oftentimes, and wash it diligently till all the fatness be come off from it into the water; afterwards press it out and lay it by, then pour that fat and filthy water out of one vessel into another, holding the vessel on high, pouring and repouring till it be frothy, then again take away the fat that swims at the top, do so so often till no more froth appear nor fat swims at top; then take the fat with the froth and wash it up and down with your hand in clear water so often and so long till the filth be washed from it, which may be known by the water remaining clear, and the fat being tasted do not bite your tongue, then keep it in a thick and clean pot in a cold place.”

There is another recipe for making the above preparation, published 1680, where it is described as free from dirt, not biting the tongue, and of white appearance.

In later *Pharmacopœias* or *Dispensatories* “Oesypus” is not mentioned; it seems it has been abandoned together with many other antique remedies, such as burnt swallows, fox lungs, man's cranium, &c.

In the year 1868, Hartmann analysed the fat obtained from wool by means of solvents and found it to consist chiefly of the ethers of fatty acids and the ethers of cholesterine with fatty acids.

Two years later, A. Schulze proved also the presence of isocholesterine ethers with fatty acids (*vide Berichte der deutschen Chemischen Gesellschaft*).

Later on Drs. Braun and Liebreich, working on raw wool-fat, so-called recovered fat, consisting, besides of the above-named substances, also of the fatty acids of the soap which is used in washing wool, took out a patent (18·2) for the purification of wool-fat, which, mixed with water, they termed “lanoline.” They described their lanoline as a combination of pure wool-fat with water.

The appearance of this preparation showed that it was far from pure, the colour of their anhydrous wool-fat was greenish-brown, and when mixed with water, dirty yellow, containing still free fatty acids, and if kept for some time, even in a closed vessel, assumed a brown colour on the surface, besides retaining the characteristic disagreeable smell of sheep. It is prepared thus:—

“Fresh lye, from wool-washing works, passes through a centrifugal apparatus in which the dirt and water are separated from each other, the raw lanoline is kneaded with cold flowing water until the water which flows away is as clear as the inflowing water.”

This process seems to be copied from the recipes of Dioscorides, Plinius and Culpeper.

“The raw lanoline is then heated with water whereby it is separated into water and fat, and the latter skimmed off. It can then be again operated on in a centrifugal apparatus, or dissolved in ether, ethylic or methylic spirits or other solvents.”

This does not seem correct, as the cholesterine ethers of the fatty acids which constitute the pure anhydrous wool-fat are insoluble in ethylic or methylic spirits.

“The solvents can afterwards be recovered. The fat so cleansed is kneaded with water, with which it combines to make a perfectly white neutral inodorous unguent. Instead of the lye, raw wool-fat emulsified with alkalis, soap, or a mixture of both is subjected to the above process.”

In December 1885 the *Fabrie Chemischer Producte* in Berlin (Messrs. Jaffe and Darmstädter) patented another

process: "In the emulsified wool-fat fat and water are separated by allowing the liquid to stand for some time, as then separation will take place spontaneously, and the upper layer consisting of the fat can then be treated as stated in the former patent, 1882. The separation also takes place and more quickly if a strong and copious jet of water is allowed to flow into the emulsion liquid. The separation may be also easily effected if, instead of soluble alkaline soaps, those of insoluble alkaline earth or heavy metals are used in emulsifying the wool-fat, but in this case the separation of wool-fat and insoluble soap is more difficult."

Other vegetable ingredients are mentioned, which tend to emulsify the wool-fat, such as pancreatine, and drugs containing saponine.

On the 8th of January 1886 the same firm applied for another patent, in which they propose to either dissolve the emulsified wool-fat in suitable solvents, such as benzene, benzol, xylol, toluol, isobutylalcohol, amylalcohol, sulphide of carbon, &c., which dissolve the fat and the existing soaps, and leave the impurities undissolved. Or to treat the raw wool-fat with such solvents as will dissolve the fat only, and leave the soaps undissolved, for instance ether and acetone. Working on raw wool-fat the fatty acids contained in the latter are saponified by alkalis, alkaline earth, or the oxides of the heavy metals, and then treated with either of the above-named solvents.

Both methods are impracticable, as the emulsified wool-fat forms, when stirred or shaken with any of these solvents, a jelly, which it is almost impossible to separate.

A patent was taken out by myself and my assistant, Mr. Ritsert, on May 7th, 1886, by which we treat the raw wool-fat with boiling alcohol, containing about 10 per cent. of ether, by which means we dissolve the free fatty acids, the free cholesterine and isocholesterine, and the volatile ethers of the free fatty acids present in the raw wool-fat. The remaining cholesterine ethers are then treated with steam in order to drive off remnants of the solvent. Or, we dissolve the raw wool-fat in ether and separate the cholesterine ethers by the addition of alcohol. Thus purified, they are mixed with about 20 per cent. of water and called by us cholesterolol.

Instead of working on raw wool-fat we may use the lyes of wool-washing works.

Wool-fat thus purified leaves much to be desired, as the presence of cholesterine ethers of higher melting point, wax-like, render it tough, and make it unfit for pharmaceutical or cosmetrical purposes.

I obtained a second patent in September of the same year, by which I use either the lyes of the wool-washing works or raw wool-fat, commercially known as recovered fat. In working with the latter, I first separate the free fatty acids by means of solvents, such as alcohol, mixed either with ether, chloroform, carbon bisulphide, acetone, benzoline, or naphtha, or by distilling the fatty acids off, preferably by superheated steam, at a temperature of 400°–450° F.

The fatty residue, after separation of the acids, is then filtered through animal charcoal, especially that known as prussiate waste, and this may be done in either of two ways: either by maintaining the fatty matter in a fluid condition by heat applied to it and to the filter, or by first dissolving the fatty matter, preferably in benzoline, carbon bisulphide, or acetone, and filtering the solution. The solvent is then recovered by distillation, and steam or warm air is blown through the fatty matter until all traces of the solvent have disappeared, when such has been used. The so purified wool-fat is anhydrous, of a yellow colour, and free from smell; if required, as basis for ointments, pomatums, &c., 20–30 per cent. of either water or a solution of peroxide of hydrogen are incorporated with it, thus producing a pure white material.

Dr. A. von Rad, of Bavaria, applied for a German patent in March 1887. In his process he precipitates the lyes of wool-washing works with slaked lime and deodorises the precipitate by means of chlorinated lime or manganate or permanganate of potash or soda. The precipitate is then dried and the wool-fat dissolved out successively by alcohol, benzene, carbon bisulphide, benzol, and a mixture of ether and chloroform, and in order to give to this fat a proper

consistency, he mixes it with neutral ethyl or methyl ethers of oleic acid and calls it "Lanesine."

Later on Dr. von Rad obtained a second patent for a process by which he heats raw wool-fat with alcohol and sulphuric acid, thereby changing the free fatty acids into the corresponding ethers.

Messrs. Singer and Judell extract the fat from wool by means of carbon bisulphide, a method tried years ago, but abandoned owing to the difficulty of rendering the wool odourless, or when driving off the solvent by heat spoiling the wool. Messrs. Singer and Judell seem to have avoided this difficulty by using a very elaborate apparatus (this Journal, 1889, 24).

In order to prepare wool for the spindles, the dirt, fat, salts, soap, &c., naturally contained in wool, must be separated from it. This is generally done by washing and scouring the wool with soap lyes, which are then called liquor, and are of a dirty, greyish, milky appearance of the smell of ordinary soapsuds when fresh, of a putrid, ammoniacal smell after standing some time, and consist chiefly of potash salts, naturally found in the fleece of sheep, of wool-fat, dirt, and soap.

Formerly this liquor was wasted: in later years it was saturated by means of acids, especially sulphuric acid, thereby recovering part of the fat. By this treatment the soap that has been used in scouring is decomposed, and its fatty acids, together with the wool-fat and dirt, form a so-called magma, from which after dehydrating the fats are obtained by hot pressure; these are then remelted, allowed to settle, and filled into casks. Till about two years ago the value of such recovered fat was 7*l.* per ton; now 11*l.*, 12*l.*, and even 13*l.* are obtained, because large quantities are used in the United States for softening leather. I am told that in the course of 12–18 months the thus greased leather deteriorates on account of the large amount of the free fatty acids present in the fat. Coarse wool contains about 7–10 per cent. of fat, whilst fine wool, such as imported from the Cape, Australia, and New Zealand, contains 30–40 and even 50 per cent.; but the liquor yields by the acid treatment only about half the quantity it contains.

By my present invention I recover all the fat as well as the potash salts, dirt, and soap used in washing wool.

The wool is twice soaked in warm water of a temperature not exceeding 110° F., and pressed or dried by centrifugal action. The water thus obtained contains the potash salts naturally present in wool, together with a small quantity of potash soap, formed by the action of potash on the cholesterine ethers and volatile acids, and also part of the dirt adhering to the wool; it is allowed to settle and then concentrated in a suitable vacuum apparatus, preferably a quadruplex Yaryan, then finally evaporated and dried, thereby obtaining the potash salts in an alkaline but impure condition; or the water is saturated with hydrochloric, sulphuric, or phosphoric acid, in order to more speedily form a sediment, and concentrated as before, thereby obtaining the potash salts as chlorides, sulphates, or phosphates. The sediment is either dried by heat, filter press, or centrifugal apparatus, or the potash salts are dried together with the dirt and used as manure. If it be desired to obtain the potash salts in a purer state, they have to be calcined, lixiviated, and recrystallised.

After concentrating the water and acidifying it the emulsion is broken up and the small quantities of fat, together with the dirt, are removed and worked up together with the concentrated liquor of the subsequent washing with soap lye.

After the first treatment with water, the wool is washed and scoured with soap lye, consisting generally of an emulsion of olive oil and potash lye, diluted with water, by which means all the fat, together with the remaining dirt, is removed and forms with the lye an emulsion; the wool is then rinsed in water, pressed, and dried. The emulsion, together with the rinsings, are as far as possible concentrated in a Yaryan apparatus and treated repeatedly with a mixture of alcohol and water, for economy's sake methylated or otherwise denaturated spirit. I take, for instance, equal parts of spirit and water, but it may be varied to three parts of spirit and two parts of water, or two parts of spirit and three parts of water.

By this treatment the emulsion is broken up and the soap dissolved in the diluted spirit, leaving behind the wool-fat and dirt; the soap and spirit are separated and recovered by distillation.

The wool-fat is then extracted from the dirt either by hot pressure or by means of solvents, such as carbon bisulphide or benzine, for instance, and the solvent recovered by distillation.

The wool-fat is then practically free from soap and dirt, and, being also free from fatty acids, forms a valuable lubricant or leather grease, or it can be further purified by my patented process described before. The recovered soap is by itself unsuitable for washing purposes, because it contains a large amount of a soap which does not give a good lather with water, besides also a small quantity of cholesterine ethers of a higher melting point, probably stearate of cholesterine, which can be separated by treatment with strong spirit.

It is advisable to filter the soap solution when cold through flannel bags; the filtered liquid consists chiefly of oleine soap and is recovered by distilling off the solvent, whilst the remnant on the filters can be made use of, after decomposition with acids, for the manufacture of candles, for instance. This remnant soap is very sparingly soluble in water, but dissolves easily in hot spirit, from which solvent it separates whilst cooling, similar to stearine soap.

I continue studying the nature of the fatty acids, of which this soap is composed, and shall later on report about it.

Sometimes it may be desired not to recover the potash salts and dirt separately; in that case the water in which the wool was soaked is to be concentrated and dried without allowing it to settle; or it may not be required to recover the soap separately. In that case the preliminary soaking of the wool can be dispensed with, and the wool-washing water is, after concentration, over-saturated with an acid, such as sulphuric acid for instance, and heated, by which means the soap is decomposed and the so liberated fatty acids of the soap, together with the wool-fat and dirt separated from the water, and recovered either by hot pressure or solvents as above stated.

Instead of concentrating the wool-washing water or liquor, common salt in sufficient quantity may be added; in this way the wool-fat, soap, and dirt, are also separated from the water, which process is quickened by heating, preferably by steam. The amount of salt required is about 12—15 per cent. of the liquor and can be used again, when recovered by concentration.

The liquor, having a specific gravity of 1.019, contains per gallon about 800 grains of fatty matter; a tank of 10 cubic feet dimension, in which the liquor is generally stored, would contain about 6,232 gallons and yield 712 lb. of fatty matter, whilst by the old way of recovering the fat, only about 300—320 lb. are obtained. For concentrating 6,232 gallons of liquor in a quadruplex Yaryan about half a ton of coals is required.

#### DISCUSSION.

The CHAIRMAN said that the thanks of the meeting were due to Mr. Langbeek for a paper so exceedingly interesting from various points of view. It was very interesting to have recalled to one's mind the ancient processes of the Greek pharmacists—who were by no means so backward as some people imagined. It was interesting, too, to be reminded that in that quaint book "*Culpeper's Pharmacopœia*," there were descriptions of processes which were still not entirely obsolete or absurd. He must confess that he was unaware of this before hearing the paper, although he thought he knew the book well, with its recipes for the manufacture of oil of puppy dogs, oil of worms, &c.; for the preservation of mummies for human consumption, and other curious things. But here, among the Greeks, and in the Middle Ages, was the knowledge of a process which had been entirely lost in modern times, until the last few years. If, 10 years ago, one had consulted a text-book on the subject of wool, the utmost information one would have got would have been that it was a pity to waste the "suint" by washing it away in a stream; that it was a valuable manure on account of the potash it contained,

&c. It was therefore very interesting to hear that this most valuable medicament had been not invented, but recovered from the oblivion into which it had fallen. It was curious to find that this lanolin, as it was now called, had, by reason of its origin, a remarkable power for penetrating the skin. If, therefore, a medicament was mixed with it and rubbed on the skin, it would be absorbed much faster than if mixed with soft paraffin or vaselin, the lanolin itself being absorbed as well as the medicament. This "dirt of wool," which a few years ago was regarded as a necessary evil, due to the scarcity of water or the conveniences for washing wool in the countries from which it was generally exported, had now come to be regarded as the source of a most useful product. Mr. Langbeek's paper, therefore, was of practical as well as scientific and historical interest. It dealt with a subject on which the information obtainable hitherto was very imperfect, and was in fact the first complete résumé of the subject he had ever seen. On this account therefore it was specially welcome.

Dr. C. R. ALDER WRIGHT had listened with great interest to the paper, the more especially because some 15 or 16 years ago he had been engaged in an endeavour to utilise the fat extracted from wool. The process, however, died in its infancy, and so brought his experiments to an end. The method he referred to was that invented by Toepler, and consisted in treating the wool with fusel oil, methodically lixiviating it, so that a concentrated solution of wool-fat in fusel oil was obtained. There were various reasons why the process was not successful. The works in which it was started were situated near Rochdale, and the perfume of the fusel oil dominated the locality and raised the ire of the residents, who, having got the idea that it was a powerful intoxicant, took measures to suppress the use of the process. But the arguments they employed on the question of injury to health were somewhat startling. It was stated that typhoid fever was caused by the exhalations of the fusel oil, and letters were written to the local papers stating that the foul odours caused all the people for several miles round to feel "drunken sick, as if on the fuddle." The results of this opposition, and the practical difficulty of obtaining fusel oil in quantity, and workmen with the requisite skill for dealing with a new manufacture, led to the suppression of the industry at an early stage. But one of the practical results was that the fusel oil solution of the fatty matters, soaps, cholesterin, isocholesterin, ethers, &c., was obtained in considerable quantities, several tons at a time. There was no great difficulty in working out a variety of products from this raw material, but whether it could be done on a commercial and paying scale had not been determined. One thing made evident was that solid fatty acids more or less mixed with unsaponifiable matters could be extracted in considerable quantity. The presence of these latter substances materially detracted from the value of the product, just as in the somewhat similar case of the "Yorkshire grease" obtained from the soapsuds of wool-scouring works by treatment with sulphuric acid, whereby a mass of fatty acids resulted mixed with unsaponifiable matters derived from the wool. One use for such material was more ingenious than desirable, namely, the adulteration of tallow used for the manufacture of soap and stearine. It was within his own knowledge that difficulties had occurred in a large stearine manufactory from the fact of their making contracts to purchase tripe tallow and such like fatty matters which were subsequently found to contain not far short of 20 per cent. of matters of an unsaponifiable character, and identified as being derived from wool-fat. He therefore felt some hesitation in accepting the statement put forward that material suitable for candles could be extracted from these substances. But as regarded the separation of the more fluid constituents, and their various uses, he thought the members owed a debt of gratitude to the author for bringing the subject before them in so neat a form, and for recalling to their recollection the ancient history of the process, as well as of various old medicaments and other bodies of curious origin. It was probably within the present century that *album Græcum* was an ingredient of the *Pharmacopœia*, substantially consisting of phosphate of lime that had passed through the body of the dog.

Personally he preferred Parrish's food, but that was a matter of taste. As to whether the exudation of the sheep's skin was materially preferable to *album Græcum*, from the sentimental point of view, must be left to personal opinion. But there could be no doubt of the correctness of the Chairman's remarks as to the value of lanolin for introducing medicaments into the system by means of external application.

Mr. HERBERT PORTER wished to ask the author a question with respect to a point which, from his practical experience of wool-washing, appeared to him to constitute a difficulty. He was quite alive to the value of the recovery of lanolin as a means of cheapening the production of wool for spinning. But there was one difficulty common to all such processes, namely, the delay in changing the wool over from the water in which it was rinsed, in order to get the fat from it, into the soap-bath. In the case of the better classes of wool, it was well known that if they got chilled before the dirt was quite removed from them, they never regained their proper colour. If, therefore, the wool had to be put into a centrifugal machine to wash out the fat, and then lifted from that into the soap-bath, unless the mechanical details were perfect there was great danger of the harm which he had indicated occurring, as he had known it to do in more than one experiment.

Mr. WATSON SMITH desired to testify to the correctness of some of Dr. Wright's remarks with respect to what might be called the illicit use of wool-grease. He had certain evidence which proved that there was a considerable excess of supply over demand in the case of wool-grease. Any information, therefore, relating to the production of this body in a useful form would be hailed with gratitude by those manufacturers who were now suffering from its illicit use in the tallow trade. Soap manufacturers had informed him that they at times received, through Hull from the Continent, parcels of tallows and fats from which they could not, by any of the recognised methods of soap manufacture, make hard soap. He had endeavoured to render professional assistance in the matter, but, after numerous practical trials, and after exhausting all the information he could give, it was found that the soap still continued to come out soft. When the manufacturers were prevailed upon to use only first-class materials, no more complaints were heard of.

Mr. H. W. LANGEBECK, in reply, said that he had had no practical experience of candle making, but he had found that the part of the by-products which would prevent soap from giving a good lather were, when decomposed by acids, of a high melting point. Different kinds of wool-grease had different melting points. In the case of ordinary wool-fat imported from France and Germany, the melting point was  $115^{\circ}$  to  $120^{\circ}$ , while that of fat from Leeds was often as low as  $90^{\circ}$ . With respect to the danger of the wool being deteriorated by several washings, he would point out that the first soaking in water was only to remove a part of the dirt and the potash salts. The larger quantity of the fat remained in the wool, and acted as a protector; and it was only by the after-treatment by the soap emulsion that this fat was removed. He had with him for inspection some wool treated by the process, and some of the wash-water in a more highly concentrated condition than it would be drawn from the Yarn. Ten gallons of liquor were concentrated by the Yarn to one gallon. He had also some of the potash salts in a purified state, and some of the ordinary recovered fat, which he had got from France. The wool-fat obtained in the North of England was generally much softer. He would also show a sample of the soap used for washing the wool, its dark colour being accounted for by the fact that it had been dissolved out by diluted spirits, which, containing acetone, form with alkalis a resinous matter of dark colour. He had some of the wool-fat free from soap, and suitable as a lubricant or a leather-grease; and also the same body more highly purified and anhydrous, viz., of light yellow colour. He was quite aware that the fat made from the by-products of wool-washing was unsuitable for giving a hard soap. It would therefore be advisable, as he had already said, to separate those soaps which were insoluble

in cold diluted spirit by filtering from those soluble in that medium, and use them, not by themselves, but in addition to soap. In that way a hard soap would be obtained. In conclusion, he might mention that the soap remaining on the filter was not soluble in water, but was soluble in hot spirits of wine.

Mr. WATSON SMITH exhibited at the close of the meeting an interesting Collection of 72 Alkaloids and Glucosides by Merck, of Darmstadt.

Meeting held Monday, 21st April, 1890.

MR. DAVID HOWARD IN THE CHAIR.

### THE OIL-FIELDS OF INDIA: NOTES ON THE PETROLEUM DEPOSITS OF BIRMA, ASSAM, THE PUNJAB, AND BALUCHISTAN.

BY ROBERTON REDWOOD, F.R.S.E.

DURING the past six months I have from time to time taken steps to put into the form of a paper the available information I have for many years collected in respect to the oil-fields of India, with the results I have obtained in the examination of typical samples of crude petroleum from that country; and as Professor Dewar and I found it impossible to carry out our intention of describing this evening our process of converting heavy oils into hydrocarbons of less density, I thought it best to complete this paper and present it as a substitute, especially as the two subjects are to some extent correlative.

Petroleum occurs in India in Upper and Lower Burma (including the Arakan islands), in Assam, in the Punjab, and in Baluchistan.

#### 1. (a.) ARAKAN.

Just south of Akyab lie the Baranga islands, and still further south the islands of Ramri and Cheduba (see Fig. II.). In Ramri petroleum occurs at Minbyin, on the western side, at Leedaung and Leikmaw, on the south-western and western coasts, respectively, and at Kyauk Phyu. It is also found in Cheduba, in the Barangas (principally in the eastern of the three islands), and elsewhere in smaller quantities. The positions of the wells are shown in the outline map (Fig. II.).

An excellent account of these islands was given in 1878 by Mr. F. R. Mallet, F.G.S., Geological Survey of India.\* The digging of oil wells in Ramri and Cheduba appears to have been an industry for a long time past. About the end of December or beginning of January, when the rice crop has been harvested, some of the villagers employ their spare time in digging wells as a means of adding to their income. The oil season lasts from that time till the rains, when the wells, which are usually sunk in, or close to, the bed of some nalka, get filled with water, and are often choked up entirely by debris washed into them. Mr. Mallet states that the wells are of two classes—those which appear to be in communication with a natural reservoir, from which the oil, generally accompanied by large quantities of gas, rises with considerable rapidity, and those sunk in rock more or less soaked with petroleum, from which the oil slowly percolates into the well. To the former class the wells at Leedaung are said to belong. One of these is about 25 ft. deep and 4 ft. square. It is lined with wood throughout. At the bottom is water covered with a stratum of oil, through which a rather large quantity of gas bubbles up, chiefly from one corner of the well. The oil is drawn morning and evening. Another well of the same kind,

\* Records of the Geological Survey of India, Vol. XI., Part 2.

about 200 yards north-west of the above, is about 40 ft. deep, with water and oil at the bottom which seem to boil gently from the issue of gas. The oil is of a pale yellow colour. Mr. Mallet was informed that these wells had been in existence since the time of the Burmese domination, and that the yield of oil had not diminished. The yield, however, was only a few gallons a day, a quantity that a large reservoir, tapped only by a small duct leading to the bottom of the well, might supply for a very long period.

As regards the future of Ramri as an oil-producing territory, Mr. Mallet makes the following remarks:—"The not unfrequent fiery eruptions from one or other of the mud volcanoes occurring in a line near Tsi Chang (near Kyauk Phyu) leaves but little room for doubt that there is a fissure beneath them in which large quantities of gas are generally stored up, and it is at least highly probable that a considerable quantity of oil is associated with the gas. A lucky boring might strike a spouting reservoir of great capacity, but of course such an undertaking would be of a speculative kind. There are no data to determine at what depth the oil is stored, nor what the inclination of the fissure may be, whether vertical or at a greater or less angle. A boring therefore sunk actually along the line of vents might miss it altogether. A few holes, however, sunk in a line at right angles to the line of vents could hardly fail to strike it if sunk sufficiently deep. The experiment would certainly be an interesting one, whether rewarded with success or not."

Mr. Mallet considers that the wells in the southern part of the Eastern Baranga are of the same class as those at Leedaung already alluded to. They are sunk in grey shale which splits with a rather smooth fracture having a slightly unctuous feel. The bedding is very nearly vertical. Particulars are given respecting the drilling of two wells in this locality. When the bore of the first well had been carried to a depth of 66 ft. from the surface of the ground, "the workmen were surprised and terrified by a sudden outburst of gas and oil, accompanied by loud subterranean sounds, as of distant thunder." The drilling had been commenced at the bottom of an excavated shaft some 30 ft. in depth, and the workmen "had only time to make their escape up the ladders of the well before the oil and gas poured in in quantities that would otherwise have made their position a very perilous one." This well is said to have yielded 1,000 gallons a day for seven days, and afterwards 120 gallons a day, but a great deal of the oil escaped from the well through fissures. In the second well oil was struck at 68 ft., and the yield was 150 gallons a day. The gas escaped with violence, "making a great noise."

Of the second class of wells those near Minbyin, in Ramri, are regarded as the most important. Here, in an alluvial plain in or near to the beds of the nullas, are several scores of wells 4 ft. in diameter, and from 5 or 6 to 10 or 12 ft. in depth, sunk in groups of a dozen or twenty in a tough grey clunch, generally covered with a foot or two of surface soil. In some wells the clunch towards the lower part is entirely soaked with petroleum, but more frequently the oil soaks the rock in patches. The wells are worked from about the beginning of December till the commencement of the wet season, when, being in the beds of nullas, they get filled with rubbish. The aggregate production is only 6,000 bottles, or about 1,000 gallons.

Mr. Mallet is of opinion that the oil-bearing rocks near Minbyin are probably at or near the axis of an anticlinal bend, a position which, as he says, has in other oil regions been found a most favourable one for well sinking. The present wells, he points out, have merely "grubbed at the surface."

Some of the more recent dug wells on this island are lined with bamboo wickerwork.

In Cheduba, according to Captain Halstead, oil is collected by turning up the soil, where oleiferous, to a depth of 2 ft., and surrounding it with a bank of earth, so as to form during the rains a shallow pond, about 20 yards square; gas and oil rise through the water, and the oil is skimmed off and collected. It is worthy of note that this was the method of collection adopted by the Indians in what are now the Pennsylvanian oil-fields.

In reference to the Arakan deposits, Mr. Medlicott,\* commenting upon the fact that so far the business of oil-winning on a large scale in these localities has not been a success, says:—"There are no doubt very large supplies of high class petroleum to be got from this region, but it must be won by suitable methods."

Allusion has already been made to the colour of the crude oil obtained in the Arakan district. Much of it has the appearance of brandy or sherry, and it can be burned in lamps in its crude state. The Baranga oil was exhibited at the Akyab exhibition in 1875, and attracted much attention. Specimens of the oil from the Eastern and Western Barangas were submitted to me for analysis in 1878.

The Eastern Baranga oil was dark brown in colour, and had a pleasant odour. Its specific gravity was .835, and I obtained from it 66 per cent. of excellent kerosene of sp. gr. .810, besides from 2 to 3 per cent. of more volatile products. Owing to the small quantity at my disposal I was not able to ascertain with any approach to precision the percentage of the solid hydrocarbons present, but I formed the opinion that about 3 or 4 per cent. of paraffin, together with lubricating oils, might be obtained from it.

The Western Baranga oil was of similar colour and odour, but of higher specific gravity, viz., .888, and it yielded only 7 per cent. of kerosene of sp. gr. .815. The residue, however, yielded an excellent lubricating oil.

About the same time I examined samples of oil from the mud volcanoes near Kyauk Phyu, and from the wells (10 to 20 ft. deep) at Minbyin. The former was an oil of pale colour, and of sp. gr. .818. It yielded 56 per cent. of kerosene of remarkably high quality, but almost the whole of the material was available for use as burning oil. The Minbyin oil had a specific gravity of .866, and yielded only 15 per cent. of kerosene of sp. gr. .810.

Portions of these samples and specimens of rock from the Barangas, saturated with petroleum, are on the table.

The following interesting comparison of the crude oil obtained in the Arakan district with that produced in Upper Burma ("Rangoon oil") will be found in Mr. Mallet's detailed description of the salses or mud volcanoes of Ramri and Cheduba.† "In this connexion the difference between the petroleum of the Irrawadi valley and of Ramri may be noticed. The mud volcanoes of the former region have been described by Dr. Oldham as very sluggish, and as never exhibiting the fiery paroxysms to which those in Ramri are subject. At the same time the oil is dark coloured, is as thick as treacle, or even solid at 60° F., being indeed often spoken of as 'Rangoon tar,' and contains paraffin to the extent of sometimes more than 10 per cent. The Ramri oils are associated with much gas, and are themselves sometimes as transparent and light coloured as brandy. They have a lower specific gravity than the above, and at 60° are perfectly mobile. Without venturing to assert that the above differences are due to a difference in the temperature at which the oils have been produced, it may be noticed that at Baku, on the Caspian, where there are mud volcanoes subject to fiery eruptions, similar to those of Ramri, the oil is in part of the same pale transparent kind, and is accompanied by immense quantities of gas."

In illustration of these remarks I have placed on the table samples of "Rangoon oil," and of the light oil obtained at Surakhany in the Baku district.

#### (b.) UPPER BURMA.

On p. 261 of the Journal of the Embassy to the Court of Ava, by Major Symes, published in London in 1795, will be found the following account of the wells from which the so-called Rangoon oil was obtained:—

"After passing various lands and villages, we got to Yenangyoung, or Earth-oil Creek, about two hours past

\* Note on the occurrence of petroleum in India, by H. B. Medlicott, Geological Survey of India. Records Geological Survey of India, Vol. XIX, Part 4, 1886.

† The Mud Volcanoes of Ramri and Cheduba, by F. K. Mallet, F.G.S., Geological Survey of India. Records, Vol. XI, Part 2, 1878.

noon. We were informed that the celebrated wells of petroleum which supply the whole Empire and many parts of India with that useful product were five\* miles to the east of this place. The month of the creek was crowded with large boats waiting to receive a lading of oil, and immense pyramids of earthen jars were raised in and around the village, disposed in the same manner as shot and shell are piled in an arsenal. This is inhabited only by potters, who carry on an extensive manufactory and find full employment. The smell of the oil is extremely offensive. We saw several thousand jars filled with it ranged along the bank; some of these were continually breaking, and the contents, mingling with the sand, formed a very filthy consistence."

Additional historical references will be found in the Journal of an Embassy to the Court of Ava, by John Crawford, published in London in 1826, and in the Narrative of the Mission to the Court of Ava in 1855, by Colonel Yule.

I have in my possession a work published in Calcutta in 1826, containing "An account of the petroleum wells in the Burma Dominions: extracted from the Journal of a voyage from Rangoon up the River Erai-Waddy to Amaralpoorah, the capital of the Burma Empire, by Captain Hiram Cox, Resident at Rangoon."

In this journal, dated January 1797, Captain Cox describes with great minuteness the petroleum industry of Burma as it then existed, and states that to him "the smell of the oil was fragrant and grateful." Captain Cox brings his narrative to a close with the following paragraph: "To conclude, this oil is a genuine petroleum, possessing all the properties of coal tar, being in fact the selfsame thing; the only difference is that nature elaborates in the bowels of the earth that for the Burmas for which European nations are obliged to the ingenuity of Lord Dundonald."

The oil district of Yenangyoung (Creek of Oil, or, literally, Creek of Stinking Water) has recently (June 1889) been officially reported upon in elaborate detail by Dr. Fritz Noetling, Palaeontologist, Geological Survey of India,† who points out that the district comprises two oil-fields situated about  $1\frac{1}{2}$  miles to the east of that place, near the villages of Twingauung (Hill of Wells) and Beme. It lies on the eastern side of the river Irrawady, and is distant about 300 miles from Rangoon or about 80 miles from the terminus of the railway at Allaunyo (see Figs. I. and III.). The country forms a tolerably level and flat plateau, rising to 260 feet above the low level of the Irrawady at Yenangyoung.‡ Through the mechanical action of water upon strata of unequal durability, mainly consisting of ferruginous conglomerate and soft sandstone, the surface has become intersected by numerous long, deep, and narrow irregular ravines. The strata unquestionably belong to the tertiary formation, and Dr. Noetling inclines to the belief that they are of no later age than Miocene. They consist chiefly of laminated and clayey sands, sometimes a little indurated so as to form soft sandstones. Some of the beds are highly calcareous, concretionary masses of sandy limestone abounding. Nodular concretions of a very hard quartzitic limestone are also found. The sandstone varies in colour from white or very pale yellow up to dark red and blue. The clays and sand-clays have a bluish-gray tint. Valuable information is furnished by the following section based by Dr. Noetling upon the records of strata perforated in the drilling of Messrs. Finlay, Fleming, and Co.'s first well at Kodaung (between the two native oil-fields, see Fig. IV.).

\* The distance is rather less than  $2\frac{1}{2}$  miles.

† Report on the Oil Fields of Twingauung and Beme, with a map and a plate of geological sections. Rangoon, June 1889.

‡ The Reconnaissance Map (scale, 1 in. to 4 miles), Survey of India, 1888, shows a line of hills running in a N.W. and S.E. direction, parallel to the course of the river, and extending from about 2 miles N.W. of Yenangyoung to about 14 miles S.E. of that place, but Dr. Noetling states that the map is incorrect, no such range of hills existing.

Thickness of the Single Beds in Feet,*	In Descending Order.	Total Depth from the Top.
3-4	Decomposed rock forming the soil .....	3-4
12-14	Soft yellow sandstone.....	16-18
11	Soft red sandstone, probably a thin stratum of soft bluish clay is imbedded	29
79	Soft sandstone of bluish-grey colour, thinly laminated, numerous beds of clay, sandy clay and sandstone alternating; occasionally thin beds of hard sandstone. The strata are feebly soaked with oil up to 50 ft. from the top .....	108
2	Hard grey sandstone.....	110
49	Bluish-grey sandstone of the same quality as before mentioned.....	159
9	Hard grey sandstone.....	159
41	Bluish-grey sandstone, the same quality as before mentioned, but probably at its base the clayey beds grow thicker.	200
20	Stiff blue clay (clunch) .....	220
40	Fine soft sand of greenish colour, frequently alternating with thin beds of dark bluish clunch, a thicker bed of which has been found at an uncertain depth, the sandstone soaked with oil ..	260
4	Hard grey sandstone.....	264
6	Soft sandstone of greenish colour soaked with oil.....	270
1	Hard grey sandstone .....	271
23	Rather hard sandstone of greenish colour alternating with beds of shale.....	294
6	Hard grey (?) sandstone .....	300
65	Soft sandstone of light greenish colour, in beds, unequally charged with oil ...	365
49	Conglomeratic (?) sandstone, or conglomerate of light greenish colour, soaked with oil .....	405

I am particularly fortunate in being able to place before you samples of the strata in question, which Mr. Kirkman Finlay has courteously procured from Burma, for the practical illustration of this paper. These samples were taken at the following depths during the progress of the drilling of the sixth well (A. No. 4).

#### Samples of Strata.

6.	190	"	244	" "
7.	244	"	272	" "
8.	272	"	280	" "
9.	280	"	330	" "

†

Dr. Noetling classifies the strata, in descending order, into four groups, of which the following are condensed particulars:—

(a.) The upper group, consisting chiefly of sandstones of brown and yellow colour, followed by similar beds of dark red and yellowish-white colour.

(b.) The second group, consisting of bluish-grey sandstones and clays alternating. The lower part of this group is fairly soaked with oil, which actually oozes out of the strata at numerous places in the ravines, but it is not to be considered as the oil-bearing formation proper.

\* In the original report there are evidently some misprints in the recorded measurements.

† A very interesting specimen, distinctly showing the oil *in situ*.

(c.) The third group, consisting of stiff blue clunch. This formation, which is usually found at a depth of 200 ft. when the well is on the top of the hill, or 100 ft. when in the ravine, immediately overlies the true oil-bearing strata.

(d.) The fourth group, consisting of the oil-bearing sandstone. These strata, the thickness of which is by Dr. Noetling considered to be as much as 200 ft., are composed of more or less soft, coarse, or fine micaceous sandstones of bluish-grey colour, changed into a more or less yellowish-green, according to the amount of oil present, interstratified with hard sandstone and blue clunch.

It is worthy of note that the clay beds thin out, and the beds of sandstone grow thicker as the depth increases, and that below a depth of 366 ft. conglomeratic sandstones are found.

Following these statements, there are in Dr. Noetling's report a number of painstaking deductions as to the occurrence and origin of the oil, but as Dr. Noetling himself frankly admits that "no opinion can be formed as to the depth at which the richest beds are to be found," that "none but the vaguest speculations could be formed," and that "bores of greater depth are certain to give further and more exact information," I venture to think that these deductions may be misleading.

The superficial area of the Twingauing oil-field, which lies between the villages of Twingauing and Enausu, is about 90 acres. The total number of the wells of all kinds, new and old, is 375, and of these 166 (44·3 per cent.) are utterly unproductive. The remaining 209 (55·7 per cent.) may be called productive, but these are divided by Dr. Noetling into "productive wells,"\* of which there are 120 (32 per cent. of the whole), and "scarcely-productive wells,"† which number 89 (23·7 per cent. of the whole).

One of the wells is 310 ft. deep (the greatest depth reached by a Burmese dug well), and another 305 ft.; the majority of the finished producing wells do not, however, exceed 250 ft. deep, the difficulties of digging beyond this depth both on account of the presence of petroleum vapour and because of "caving" being very great. It follows, therefore, that these wells drain but a small depth of the oil-bearing sandstone.

The production of the wells varies considerably. The 89 "scarcely-productive" wells probably do not yield more than 10 viss per diem each, on the average. On the other hand, the average daily yield of the "productive" wells may be considered to be not less than 80 to 90 viss, and is probably more than that amount. Some of the wells, however, appear to yield from 100 to 300 viss per day, and one is stated to produce 500 viss. It is obviously very difficult to obtain accurate information as to the production, and the data collected by Dr. Noetling appear scarcely to warrant all the conclusions which he draws from them. It is, however, evident that, as might have been expected, the deeper wells are the more productive.

The wells are shafts 4 to 4½ ft. square. Over the mouth of the well a cross-beam on uprights is erected, and in the centre of this is a drum and axle fashioned out of a single piece of wood and running in naturally grown fork-shaped supports. Over the drum passes a leather rope used to lower and raise the workmen or the earthenware pot (yenanoie) in which the oil is collected. If possible, the well is so situated that the men or women who are drawing up either the pot filled with oil or the digger, walk down an inclined plane along the slope of the hill. The instrument used in digging is about 4½ ft. in length, and consists of a wooden handle deeply notched 6 in. below the top, and provided with an iron shoe. In working, the digger grasps this tool with both hands a little above the shoe, and leaning the notch against his shoulder forces the instrument into the ground, and thus loosens small pieces of the rock, which are brought to the surface in a basket. The shaft is roughly lined throughout with timber. The workman is lowered in a rope sling, and as no artificial light can be used in the well owing to the presence of inflammable gas

or vapour, his eyes are bandaged before his descent, so that time may not be lost in his becoming accustomed to the comparative darkness in which he has to work when the well has reached a considerable depth. The presence of petroleum vapour renders breathing difficult, and Dr. Noetling found that the maximum time during which a young and strong man was able to remain at work was 290 seconds.

As an illustration of the difficulties under which the work is conducted, I may mention that an adventurous European with whom I am acquainted informed me that he caused himself to be lowered into one of the deep native wells, and was so quickly overcome by the gas that he became insensible before he reached the bottom, and did not regain consciousness until some time after he had been drawn up.

I am surprised that some arrangement for ventilating the wells, such as is compulsory in Galicia, is not adopted. Even in the Japanese oil-fields, as I have pointed out on another occasion,\* it is customary to employ a primitive form of blowing apparatus to supply air to the men employed in digging the wells.

As a rule four men are employed in the digging of a well. The oil is drawn up in the special earthenware pot already alluded to, suspended by a cord fastened round the neck, and is poured into another earthenware vessel of the same shape, holding from 10 to 16 viss. Twelve of these are packed in each country cart for conveyance to the riverside.

The whole area of the Beme oil-field is about 35 acres, and the total number of wells does not exceed 151. Of these not more than 72 (47·6 per cent.) are productive. Fifty of the productive wells yield more than 20 viss per day, and 22 less than 20 viss per day, the daily average amounting to 60 to 70 viss. The depth of the Beme wells is not as great as that of the Twingauing wells, and, according to Dr. Noetling, their yield is smaller, not a single well producing more than 165 viss per day, while those giving more than 100 viss are scarce.† The wells are, however, of greater age.

The wages paid for digging range from 1 rupee 5 annas to Rs. 10 per attauing,‡ according to the depth reached. The total cost of sinking a well in the Burmese fashion is from Rs. 1,000 to Rs. 1,500, and the time occupied in the operation is from 8 to 12 months. Each twinza has a right to the ground immediately surrounding his well for a distance of 14 enbits.

Messrs. Finlay, Fleming, and Co. inform me that they estimate the present total production of the Yenangyoung fields at 200,000 to 250,000 gallons per month.

The general configuration of the Yenangyoung oil-fields is shown in the sketch-map, Fig. IV., which is reduced from the map accompanying Dr. Noetling's report. The ground, as will be seen, is very broken, being intersected with choungs or ravines, some of which are from 200 to 250 ft. wide and from 100 to 150 ft. deep. This renders the transport of machinery laborious and expensive. The only wells which have as yet been drilled are those of Messrs. Finlay, Fleming, and Co.; these are located at Kodoung, which, as will be seen, lies about midway between the Twingauing and Beme fields. Drilling was commenced here in 1887, and in all nine wells have been put down, the first two by Canadian drillers, and the remainder by Pennsylvanian drillers, of whom a competent staff, provided with all the modern appliances, have now been at work about 15 months. The first two wells were not successful, one having been abandoned in an incomplete state, and the other yielding but a very small quantity of oil. Of the seven drilled by the present staff, one is a "dry hole," and another yields only a plentiful supply of water containing so much saline matter, largely consisting of magnesium sulphate, that it cannot be used for the steam

\* Yielding from 20 viss upwards per diem. 1 viss = 3·67 lb. avoird.

† Yielding less than 20 viss per diem.

\* Cantor Lectures on Petroleum and its Products. Society of Arts.

† These figures are of more recent date than the records of production included in the tabular statement relating to the Beme wells, to which I shall presently have to direct attention, and the differences between the two estimates are probably due to an actual diminution in the yield of the wells.

‡ One Tawng or attauing = 18 in.

boilers.\* Of the remaining five wells, the depth of which ranges from 225 to 412 ft., it will be sufficient for me to say that the production varies from 3 to 15 barrels per well per 24 hours. Even putting the first two wells out of account, these, it may be said, are not very encouraging results to have achieved during the 15 months that the present staff have been actively at work. It must, however, be borne in mind that in every new oil district there is much to learn, and it often happens that considerable time is occupied in determining what is the method of working best suited to the requirements of the case. Apart, however, from the difficulties attending all pioneer enterprises, there are, no doubt, special obstacles to rapid progress. Until recently, the country round the wells was overrun by dacoits, and at one time the Burma Oil Company had to suspend operations, having had several of its men killed and wounded. Even now the work is carried on under the protection of a squad of armed native troops, who guard the wells day and night. One great cause of delay and expense is the tendency to "caving," which seems very marked. Another trouble has been the scarcity of water, the necessary supplies, not only for drinking, but also for the steam boilers, having to be carried from the river, a distance of nearly 2½ miles. Messrs. Finlay, Fleming, and Co. are, however, just completing a pipe line for pumping water up from the river and oil down to it. As regards the future of the fields, Messrs. Finlay, Fleming, and Co. appear to entertain no doubt whatever of the existence of considerable quantities of petroleum, but their experience is that the yield per well is comparatively small and the cost of drilling very great. In this connexion it should, however, be noticed that the wells yet drilled are of little depth, and that only

what may be regarded as the first oil-sand has been tapped. No one can say what may be found at greater depths, but it is at least possible that far more productive oil-bearing strata may be met with.

Messrs. Finlay, Fleming, and Co. are now making arrangements to drill deeper, in the hope of striking a second oil-sand, and very great interest and importance will attach to the results obtained. I may add, that no flowing well has yet been obtained in this district.

I have already stated how the oil from the native wells reaches the riverside. There it is poured from the earthenware vessels either into the native boats or into the flats\* belonging to Messrs. Finlay, Fleming, and Co., in which it is conveyed to Rangoon by the steamers of the Irrawaddy Flotilla Company. One of the flats is shown in the view of the riverside at Yenangyoung; and, through the kindness of Mr. Kirkman Finlay, I am able to place before you a model of one of the native boats in which a small proportion of the crude oil is carried up river in bulk, for use in lamps of primitive character. The oil is worth about 1½d. per gallon wholesale, delivered at the riverside, but is to some extent retailed to the natives at a very much higher price.

On the subject of the physical and chemical characters of the oil, Dr. Noetling mentions that he had no opportunity of making the necessary examination, and he adds that he considered this "of little importance, as a sufficient supply of samples is easily to be got at any time, and can be examined everywhere." Under these circumstances, I am specially glad that I am able to submit for your inspection a representative series of samples of the crude oil which Messrs. Finlay, Fleming, and Co. kindly forwarded to me a few months ago. These include crude oil from:—

Locality.	Specific Gravity.	Setting Point.	Flashing Point (Abel Test).	Viscosity by Redwood's Viscometer, § Rape Oil at 60° F. = 100.

§ Viscosimetry or viscometry. This Journal, 1887, 121 and 148.

It will be noticed that the whole of these oils are opaque in bulk, and of dark greenish colour by reflected light. They possess but little odour, and what there is cannot be considered offensive. Owing to the presence of an unusually large proportion of solid hydrocarbons, many of the samples, as will be seen, are solid at common temperatures.

There is a remarkable absence of uniformity in the character of the oil obtained from the native wells, even where the wells are contiguous and of the same depth. This is very clearly shown in the tabular statement relating to the wells in the Beme field on the following page.

These results are very instructive. They distinctly indicate that there are at least two descriptions of oil, viz., one which has a high specific gravity and viscosity, but containing practically no solid hydrocarbons, and another of much lower specific gravity, but containing a very large proportion of paraffin.

Thus wells 26, 27, 28, 31, and 33, the depth of which ranges from 100 to 160 cubits, yield oils ranging in specific gravity from .915 to .925 which contain little or no paraffin; while, for example, wells 54 to 61 inclusive, the depth of which is from 110 to 115 cubits, yield oils of sp. gr.

.870 to .875 which are very rich in paraffin. Wells 62, 64, and 76 yield oils of .950 to .956 containing no paraffin, but these wells are so shallow that they probably yield only surface oil, though it may be pointed out that well 49, which is of about the same depth, gives an oil of sp. gr. .905 which is very rich in paraffin. To a large extent, no doubt, the lower density of the oils containing paraffin in large quantity is due to the fact that the specific gravity of the solid hydrocarbons is not as great as that of the oils in which they are dissolved, for it has been shown by Beilby† that paraffin in solution in a mineral oil has practically the same specific gravity as when in the molten condition.

I may mention in this connexion that I have found the coefficient of expansion of Burma crude oil containing much paraffin to be considerably lower than those of ordinary American and Russian petroleum.

The heavier oils, containing but little paraffin, are to some extent separately collected and employed in the manufacture of lubricating oil of high viscosity.

The occurrence of oils in this field containing no paraffin is an interesting and important fact which has not, to my knowledge, hitherto been recorded, the Yenangyoung petroleum being always described as extremely rich in paraffin.

\* Since this was written, telegraphic information has been received, and kindly communicated to me by Mr. Finlay, to the effect that this well has been deepened to 675 ft., and now yields a fair quantity of oil, though much difficulty is experienced in excluding the water.

\* These carry about 100,000 gallons in bulk.

† Jour. Chem. Soc., XLIII., 388.

I have exposed the heavy crude oil from this district to a temperature of 0° F. without causing solidification or even the slightest separation of solid hydrocarbons. In this respect the oil in question resembles much of the petroleum obtained in the Baku oil-field.

The great variation in the quality of oils obtained from neighbouring wells of the same depth appears to indicate that considerable uncertainty must, for the present at any rate, necessarily prevail as to the description of oil obtainable from a drilled well in this locality.

It is worthy of note that the oil obtained from Messrs. Finlay, Fleming, and Co.'s drilled wells is not of lower specific gravity than that yielded by some of the dug wells of the natives. This is not in accordance with experience in other petroleum-producing countries, and in this connexion it may be noticed that the No. 4 drilled well gives at somewhat greater depth slightly denser oil than the No. 2 drilled well. It may, however, be found that still deeper wells will give lighter oil than any yet obtained in this locality, presuming, of course, that oil-bearing strata are found at considerably greater depths, of which, at present, there is no direct evidence.

I have subjected a portion of the sample from No. 2 well to fractional distillation, and I find that under atmospheric pressure it begins to distil at 260° F., but less than 30 per cent. distils within the range of the mercurial thermometer. The specific gravity of the first tenth by volume is ·779. The total distillate amounts to 95 per cent., and the last half of this solidifies at 50° F. Twenty-seven and a half per cent. by volume (equal to about 26 per cent. by weight) of kerosene of sp. gr. ·823 and flashing point 73° F. is obtainable, and about 1·4 per cent. of the more volatile hydrocarbons has to be eliminated in order to get an oil of this flashing point. The kerosene is easily refined and is of good quality. The heavy oil contains paraffin amounting to from 10 to 12 per cent. of the crude oil, and the carbonaceous residue, when the distillation is conducted to dryness, amounts to 2·15 per cent., the loss (incondensable gases, &c.) being equal to 2·75 per cent.

By the adoption of the process devised by Professor Dewar and myself (which we hoped to have been able to describe this evening), it has been found practicable very

largely to increase the yield of burning oil (kerosene) of low specific gravity. We have, in fact, succeeded in obtaining from 70 to 80 per cent. of this product (a sample of which is on the table) from Messrs. Finlay, Fleming, and Co.'s crude oil, but we shall be in a better position to discuss this point when we have completed further experiments on a large scale.

The native Rangoon oil industry is well known to be one of great antiquity, but until within the last 35 years the oil was used in the crude state. In 1854 Mr. Warren de la Rue obtained a patent\* for improvements in treating products from petroleum, the crude oil with which he experimented being imported from Rangoon. For some time afterwards the refining of this material was carried on by Price's Patent Candle Company, and by Messrs. Charles Price and Co. In 1857 Messrs. De la Rue and Müller published an "Account of the Chemical Examination of Burmese Naphtha or Rangoon Tar,"† and on the 26th March in the following year, the Rev. John Barlow, vice-president and secretary of the Royal Institution, described at a meeting of that institution the "mineral candles" and other products manufactured at Belmont and Sherwood.‡

Messrs. De la Rue and Müller state that the raw material which they examined has, at common temperatures, "the consistence of goose-fat; it is lighter than water, has usually a greenish-brown colour, and possesses a slight odour, peculiar, but not disagreeable. For the purpose of the investigation several tons of the oil was carefully collected at the source and transmitted to Europe in well-secured vessels, and even this large supply was not found sufficiently ample for the complete examination of several constituents such as organic bases, "the presence of which in minute proportion was established beyond a doubt."

The raw material was distilled in a current of steam (first of a temperature of 212° F., and subsequently superheated), and thus furnished 96 per cent. of volatile products, fluid and solid. Steam at 212° F. volatilised 11 per cent. of oil perfectly free from solid hydrocarbons; between 230° and 293° F. 10 per cent. of a further distillate almost free from solid hydrocarbons was obtained. On raising the temperature of the steam to the fusing point of lead, an additional 20 per cent. distilled over, and this retained its fluidity at 32° F., although it contained an appreciable quantity of solid matter. At this stage of the process the products of distillation began to solidify on cooling, and about 31 per cent. of a crystalline material was obtained sufficiently consistent to be submitted to pressure. After that the consistency of the products of distillation began to diminish, and at a considerably higher temperature 21 per cent. of a mixture of solids and liquids distilled, the latter predominating, especially towards the latter part of the operation. In the last stage of the process the distillate completely changed its character, becoming very dark in colour, of a pitch-like consistence, and exhibiting scarcely an indication of the presence of crystalline matter. When this product, which amounted to about 3 per cent., had passed over, there remained in the still a coke-like mass, which contained a small quantity of earthy impurities. By exposing the distillates obtained beyond the temperature of 293° F. to a freezing mixture, nearly all the crystalline matter solidified and became removable by means of filtration and pressure. It was thus ascertained that the raw material operated upon contained from 10 to 11 per cent. of solid constituents (paraffin).

The solid product was purified by being subjected to the action of boiling concentrated sulphuric acid and then washed, first with an alkaline solution, then with water. On redistillation it was obtained quite white.

In order to purify the liquid products they were twice redistilled in a current of steam. They were then subjected to fractional distillation, but it was found impossible thus to separate the various hydrocarbons, notwithstanding the

large quantity of material operated upon, and recourse was had to the action of sulphuric and nitric acids. The proportion removable by these acids was found to be in most cases relatively small, but it increased with the boiling point of the fluid, varying from less than one-tenth to nearly one-third. In this manner the nitro-compounds of various members of the benzene series were isolated.

The novelty of the substances described was stated by Mr. Barlow to consist in the material from which they were obtained, the process of manufacture, and their chemical constitution. The raw material was described as the semi-fluid naphtha drawn up from wells sunk in the neighbourhood of the river Irrawady, in the Burmese Empire, and it was stated that this material was used by the natives as lamp-fuel, as a preservative of timber against insects, and as a medicine. The crude oil was imported in hermetically-closed metallic tanks. The physical resemblance of the products to those previously obtained by Reichenbach, Christison, Gregory, Reece, Young, Wiesman (of Bonn), and others from peat, coal, &c. was referred to, but it was pointed out that the latter were obtained by the decomposition of the raw material, while De la Rue's process from first to last was one of "simple separation without chemical change."

In the process of manufacture as carried out by Mr. George Wilson at the Belmont and Sherwood works, the crude oil was first distilled with steam at 212° F., about one-fourth being thus separated. By a second or even a third distillation the distillate was fractionated into products ranging in specific gravity from .627 to .860, and in boiling point from 80° F. to upwards of 400° F. These products were all colourless and free from solid hydrocarbons. The vapour of the most volatile was found to be highly anæsthetic. The more volatile distillates were commercially employed for detergent purposes under the name of Sherwoodole, and the less volatile as lamp oil. A small percentage of products of the benzene series was obtained.

The residue of the distillation with steam at 212° F. (amounting to three-fourths of the whole) was fused, treated with sulphuric acid, washed, and distilled with superheated steam. The boiling points of the oils thus obtained ranged from 300° to 600° F. The distillate from 430° F. and upwards contained the solid paraffin, for which the commercial name of Belmontine was proposed. The oils from which the paraffin was separated were found to possess valuable lubricating properties.

In 1865—66 Messrs. C. M. Warren and F. H. Storer,\* in the United States, obtained from Rangoon petroleum the olefines  $C_{10}H_{20}$  to  $C_{13}H_{26}$ ; also probably  $C_5H_{12}$ , and the paraffins  $C_7H_{16}$  to  $C_9H_{20}$ . They also found naphthalene, and their experiments indicated the probable presence of xylene and cumene. In this investigation only the more volatile portions of the crude oil were dealt with, and the results obtained appear to indicate a preponderance of olefines over paraffins.

The developments now in progress in the oil-fields of Upper Burma may therefore be regarded as the revival of an old industry under the altered conditions of improved methods of obtaining the crude oil, and the adoption of the principle of manufacturing the commercial products at the port of shipment, a principle which prevails in competitive petroleum industries. This revival dates from 1870, when the Rangoon Oil Company, Limited, erected a refinery at Rangoon. The oil wells being, however, situated in the King of Burma's territory, great difficulty was experienced in obtaining supplies of the raw material at prices which admitted of carrying on a profitable industry, and in 1876 the company was wound up. Shortly after the annexation of Upper Burma in 1886, the work having been carried on under great difficulties in the interval of 10 years by Messrs. Finlay, Fleming, and Co., the Burma Oil Company, Limited, was formed, and at once proceeded with the extension of the refinery on the bank of the river at Dumdledaw, close to Rangoon.

\* "Improvements in treating products arising from the distillation of a certain tar or naphtha, to render the same suitable for dissolving or removing fatty or resinous substances."

† Phil. Mag. (4) XIII., 512; Proc. Roy. Soc. VIII., 221.

‡ Proc. Roy. Inst. II., 506.

\* Mem. Am. Acad. IX.

This factory is capable of refining about 500,000 gallons per month, but at present the total yield of the oil-fields is less than half that quantity. The crude oil is found to yield on the average about 27 per cent. of fair standard kerosene, but the company manufacture principally a burning oil of higher specific gravity for use by natives as well as Eurasians, and of such oil a much larger percentage is obtained. The sample of this product on the table has a specific gravity of .840 and a flashing point of 121° F. (Abel test). Much of the crude petroleum from the Yenangyoung field contains, as already stated, from 10 to 12 per cent. of solid hydrocarbons, but it is important to note that, in consequence of the unfavourable conditions under which the work is necessarily

conducted, Messrs. Finlay, Fleming, and Co. do not practically obtain from the average raw material more than 4½ per cent. of paraffin, samples of which in the crude and refined states are before you. The "melting point" (English test) of the former is 125½° F., and of the latter is no less than 132° F. The company has a candle-making department, but finds it impossible to compete against the Dutch stearin candles, which are sold at an extremely low price, and the paraffin is accordingly exported to London. The other products include "naphtha" of sp. gr. .813 and flashing point 67° F. (Abel test) as well as intermediate and lubricating oils. I find that samples of the latter which are on the table furnish the following results on examination:—

	Specific Gravity at 60° F.	Flashing Point.		Viscosity.* Rape Oil at 60° F. = 100.		Cold Test.
		Closed.	Open.	At 70° F.	At 140° F.	
Lubricating oil (3) .....	.920	° F. 238	° F. 266	34.23	9.24	Ceases to flow at 30° F.
Lubricating oil (4) .....	.930	330	354	73.76	12.47	Ceases to flow at 30° F.
Lubricating oil (5) .....	.931	330	360	121.02	15.71	Ceases to flow at 42° F.
"Valvoline" (6) .....	.949	400	422	25.95 (at 200° F. .02)		Ceases to flow at 45° F.

\* By Redwood's Viscometer.

The colour of the first sample (3) by Lovibond's tintometer, in a 2-in. cell, series 500, is 130; and of the second sample (4) is 224. The specific gravity of these oils is in each case very high in relation to the viscosity, and the viscosity is affected to somewhat more than the average extent by alterations in temperature.

More than once during the past few years I have had occasion to report upon the commercial products obtained by the Burma Oil Company, and I am in a position to state that the difficulties which at first attended the manufacture have to a large extent been overcome. The extreme heat of the climate, however, is a great drawback, and necessarily renders costly the operations connected with the separation and purification of the paraffin.

The only other locality (see Fig. III.) in Upper Burma where petroleum has been actually collected in notable quantity is Pagan-Kyet, about 10 miles above Pagan, or about 50 above Yenangyoung, on the opposite or west bank of the river Irrawady. Here there are 14 wells which about a year ago were officially stated to yield about 8,000 viss of oil per month. For some time past Messrs. Finlay, Fleming, and Co. have refined the produce of these wells together with the Yenangyoung oil at Rangoon, but the yield of the Pagan wells has been steadily diminishing and is now very small. The firm in question have, however, obtained a concession and are about to commence drilling in the Pagan oil-field. I find that the oil from this locality, a sample of which is on the table, has a specific gravity of .837, a setting point of 60° F., and a viscosity of 5.91 at 90° F. (rape oil at 60° F. = 100). It is therefore of considerably less density than the Yenangyoung oil, and it yields a larger percentage of kerosene, but a very much smaller percentage of paraffin.

At Minbu, about 18 miles below Yenangyoung on the opposite or west bank of the river, petroleum also occurs, but the deposits have never been commercially worked, though here, as near Pagan, Messrs. Finlay, Fleming, and Co. have arranged to drill. The oil occurs at Minbu, just as it does in the island of Ramri, in the immediate neighbourhood of mud volcanoes. The general character of the locality is clearly shown in the series of four photographs for which I am indebted to Mr. Finlay. The oil springs are in a valley running north and south, bounded on the east side by a range of hills behind Minbu cantonment, and on the west by low hills and broken ground covered with cactus and scrub as at Yenangyoung. Photograph No. 1 shows a sort of tank made by the natives at the upper end of this valley. In

this tank gas and oil are constantly bubbling up, and around it are innumerable small springs where gas is freely emitted and may be lighted with a match. Photograph No. 2 represents an active mud volcano about half a mile from the oil springs already referred to. The conical hill has been formed by the ejected mud, and at intervals of a few seconds there is a distinctly audible outburst of gas accompanied by a little water and mud. The gas can be ignited at the apex of the cone. The mud consists of a very fine bluish coloured clay mixed with a little gravel. Photographs Nos. 3 and 4 represent other similar volcanoes situated at a distance of 200 yards and 100 yards respectively from the one already described. It is said that a Burman commenced digging a well in this spot many years ago, but had to desist "as it was too hot for him."

Among the other specimens before you are samples of the mud from these volcanoes containing petroleum, and of the oil from the neighbourhood partially freed from sand.

Petroleum is found in various parts of the Yaw country (west of Pagan), where it is collected to some extent in pits 3 or 4 ft. deep. This oil is said to resemble Arakan oil, but I have not seen a sample of it. Petroleum is also reported to have been observed in the Chindwin Valley, which lies due north of Pagan.\*

Other localities in which there are promising indications are at Padaukpen, west of Thayetmyo (where a small quantity of oil slightly lighter than the Pagan oil is obtained), and at Yenatong, west of Myanong. These are both in Pegu, and cannot therefore be included in the Upper Burma deposits.

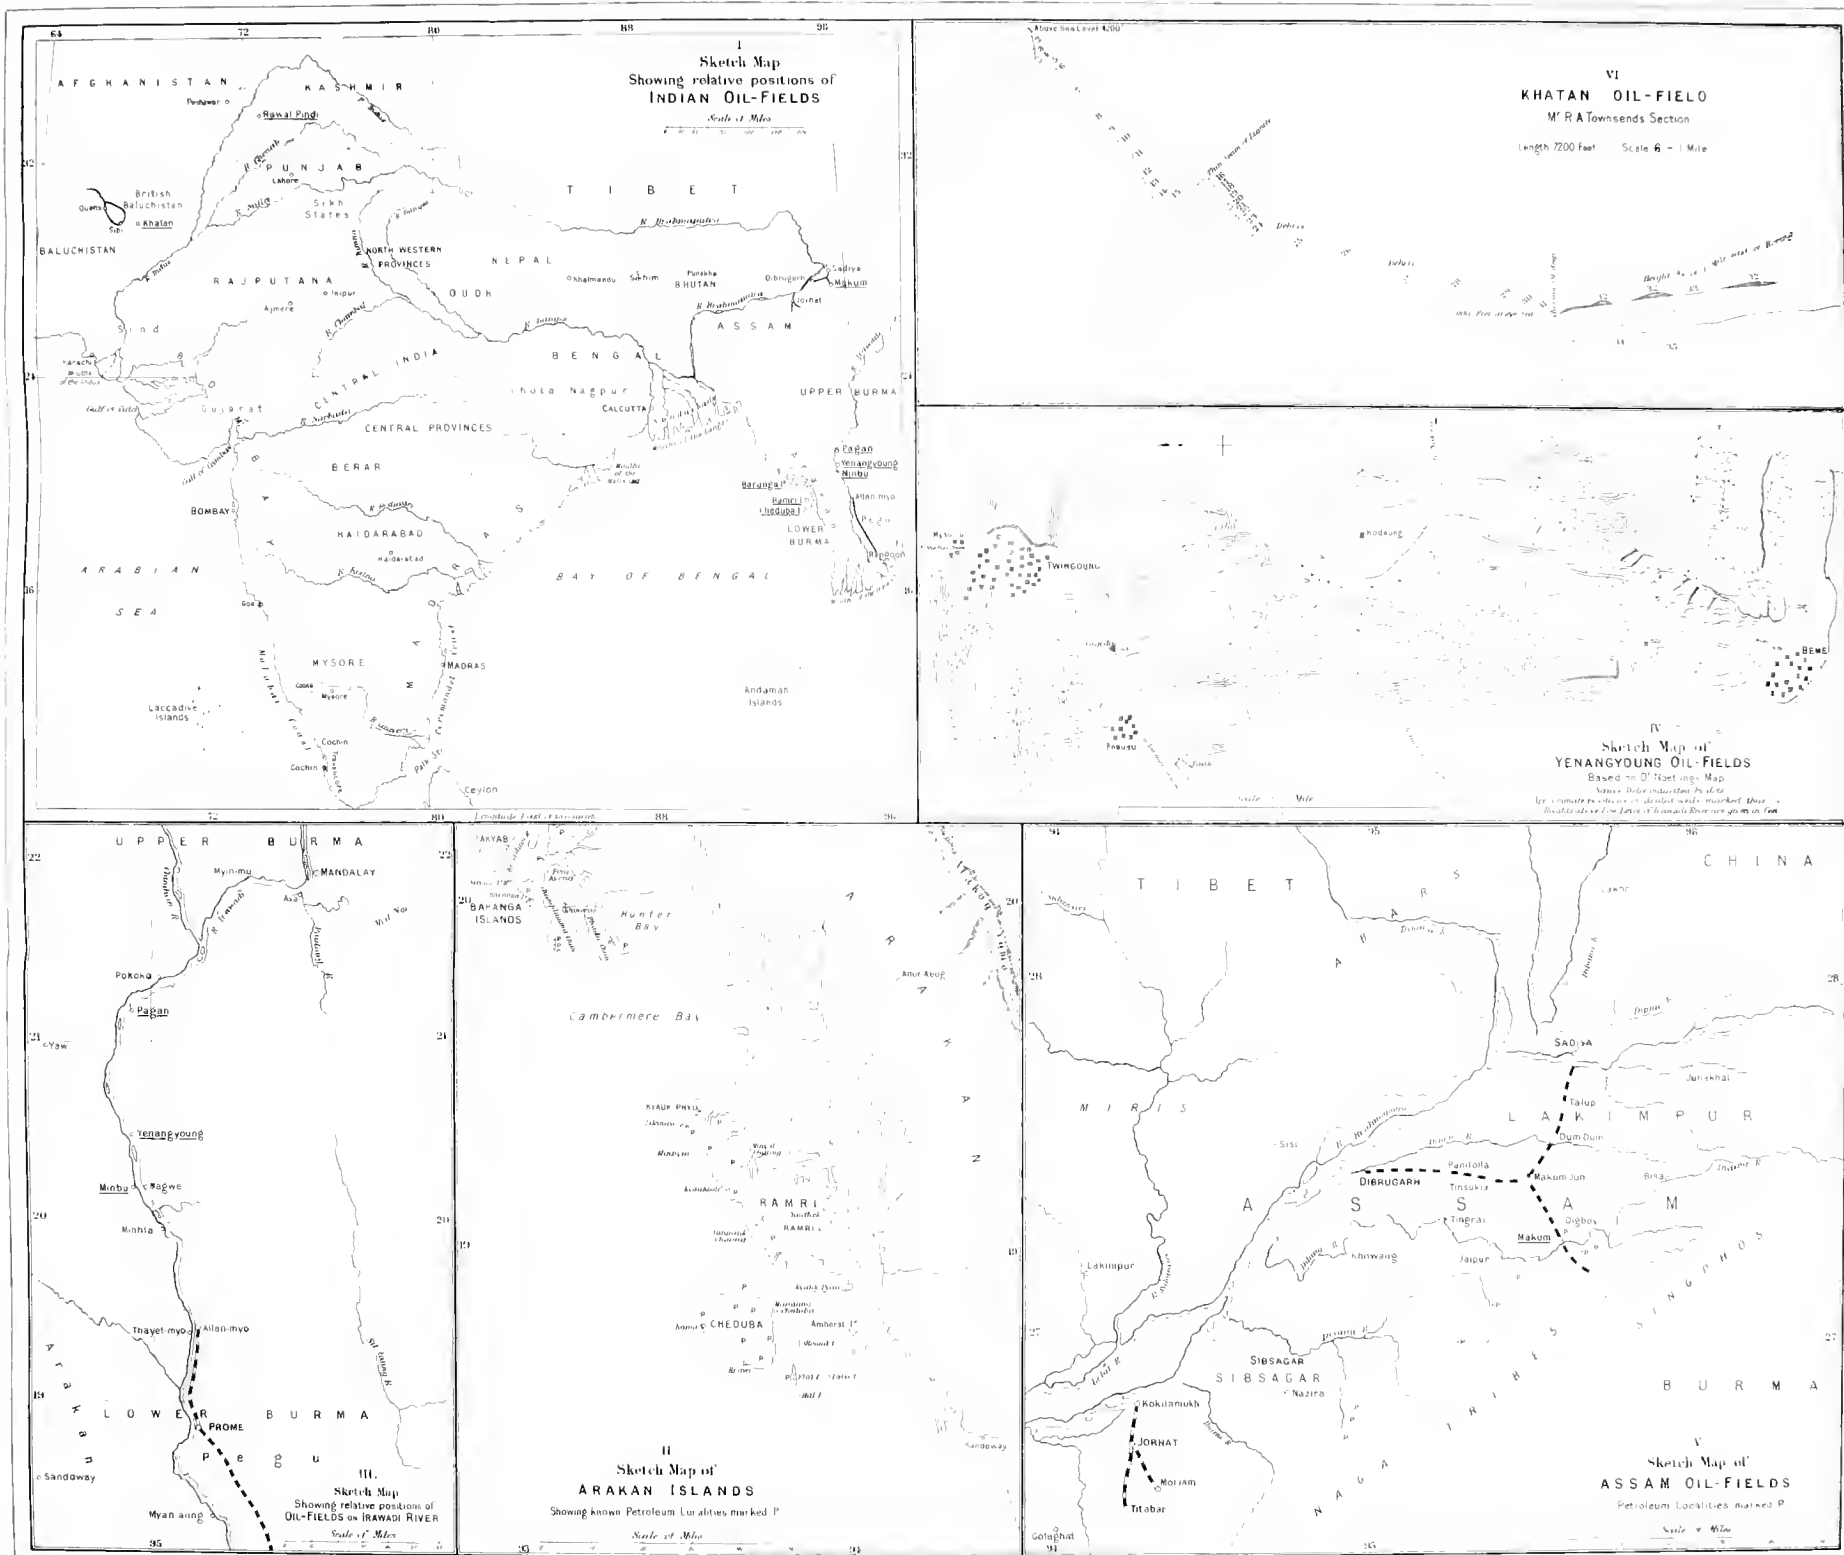

I cannot conclude my remarks on the oil-fields of Upper Burma without a cordial expression of thanks to Mr. Kirkman Finlay, of the Burma Oil Company, Limited, who, in the course of a lengthened residence in that country, has acquired an intimate practical knowledge of the subject, and has kindly furnished me with much valuable information and a large number of highly instructive illustrative specimens.

I should also like to take this opportunity of saying that our knowledge of the various petroleum deposits in India has been very effectively popularised by the pen of Mr. Charles Marvin, and I have no doubt that the intelligent

\* It was reported in Yenangyoung, on the 26th February last, that Dr. Noetling had found springs of oil resembling those of Minbu at a place called Indin, some 50 miles inland from the Chindwin river (see Fig. III.).

interest which is now taken in the subject is very largely due to the information which that graphic writer has made public.

## 2. ASSAM.

As long ago as 1825, Lieut. Wilcox, in an expedition up the Dihing River, observed a seam of coal in the bed of the Buri Dihing at Súpikong, in Upper Assam, near which petroleum rises to the surface.\*

In 1828, Mr. C. A. Bruce observed petroleum springs in more than one locality, and in 1837 Major White discovered several springs of petroleum close to the camp on the Námúp River, which had hitherto been unknown to Europeans, and apparently almost unused by the neighbouring Singphos.†

In 1837—38 Captain S. Hannay noticed petroleum rising from some of the coal outcrops, and in 1845 he described his search in the neighbourhood of Jaipur for petroleum. He also visited the Námchik River, and of this locality he writes:—"At Namtchuk Pathár, near the mouth of the river, the petroleum exudes from the banks, and a bed of very fine eaking coal runs across the bed of the Namtchuk. The hills here are also intersected by ravines, and in one spot an extensive basin or hollow is formed at some height, which contains muddy pools in a constant state of activity, throwing out, with more or less force, white mud mixed with petroleum. This is indeed a strange-looking place, and I am told by the Singphos that at times there is an internal noise as of distant thunder, when it bursts forth suddenly with a loud report, and then for a time subsides."‡

In 1865, a brief account of the petroleum springs in connexion with the coal-fields in Upper Assam was given by Mr. H. B. Medlicott.§ The most abundant springs visited were those near Makum, where Mr. Medlicott recommended that trial borings should be made, the copious discharge of gas and non-discharge of water being regarded as favourable indications.

In November of the following year, Mr. Goodenough, a member of the firm of McKillop, Stewart, and Co., having been granted certain rights over a large tract of land on both sides of Buri Dihing, extending from Jaipur to the effluence of the Noa Dihing, commenced boring at Nahor Pung. In addition to several holes drilled by hand, one of which was 102 ft. in depth, a well was carried down to a depth of 195 ft. by the use of a Mather and Platt's steam-boring machine, but according to the account published by Mr. T. H. Hughes in 1874|| (dated Raiganj, 1st December 1873), no good results were obtained in this locality, though a few signs of gas were noticed. While these borings were in progress, others were begun at Makum.¶

Oil was struck in one hole on the 26th March 1867, at 118 ft., and it immediately rose 74 ft. in the bore, being 44 ft. below the surface. About 300 gallons were drawn, after which it was found not to flow continuously, a circumstance which it was hoped would be remedied by sinking deeper. Eight holes were put down in the Makum district, and they were nearly all successful in tapping oil, though the yield varied in each. In January 1868, 100 to 125 gallons a day were collected from No. 4, while No. 5 yielded from 550 to 650 gallons. The action of No. 5 bore was intermittent. Pure water was spouted for three or four hours, then almost pure oil for 15 to 30 minutes, after which all action ceased for an hour, or sometimes longer, and then activity set in again. The discharge from No. 5 bore was at times so copious that there was not storage accommodation for the oil, and the flow was accordingly diminished by fixing a valve on the well pipe. The pressure exerted by the oil during the flow was 30 lb. to the inch.

The following interesting table gives the times of occurrence and duration of the flows or "blows" from No. 5 bore, with the quantity of oil discharged:—

Date.	Com- menced to run.	Day and Hours running.	Gallons per Day of 24 Hours.	Remarks.
1868.				
Jan. 8	9 a.m.	6 15	530	Stopped gradually.
" 16	11 a.m.	0 12	1,500	1,500 galls. in 12 hours, very strong blow.
" 17	11 a.m.	0 14	2,100	2,100 galls. in 14 hours, very strong blow.
" 20	Midnight	0 9	500	500 galls. in 9 hours.
" 21	10 a.m.	0 20	450	450 galls. in 20 hours.
" 23	11 a.m.	1 13	300	300 galls. per day, ran slowly.
" 27	9.30 a.m.	0 23½	300	do. do.
" 29	9.30 a.m.	6 15	250	Running very slowly.
Feb. 5	9 a.m.	0 19	500	500 galls. in 19 hours.
" 7	9 a.m.	2 0	700	
" 13	2 p.m.	0 19	1,400	1,400 galls. in 19 hours.
" 16	9 a.m.	1 6	1,600	1,600 galls. in 30 hours.
" 17	11 a.m.	1 5	900	In 20 hours,
March 2	9.30 a.m.	1 6	1,700	In 30 hours.
" 7	9 a.m.	2 0	3,000	3,000 galls. in 18 hours.
" 11	9 a.m.	1 11	3,500	In 35 hours; very strong, burst pipes.
" 31	10 a.m.	31 22	500 per day	Valve very little open, to reduce the flow as much as possible.
May 14	6 p.m.	60 0	450 per day	
July 14	11.30 a.m.	3 22½	100	
" 19	9 a.m.	4 21	550	
" 27	1 p.m.	0 15	600	In 15 hours.
" 28	10.30 a.m.	3 1	700	A strong blow.
Aug. 8	9 a.m.	0 3	500	In 3 hours, very strong flow.
" 11	2 p.m.	3 10	1,500	
" 22	9.30 a.m.	0 8	400	In 8 hours.

Here the man who kept the account fell ill, and the one who relieved him never kept any.

Notwithstanding these highly promising results, the great difficulties of transport appear to have brought about the failure of the undertaking; but in recording this Mr. Hughes remarks that "the prospect of an abundance of mineral oil in Assam has been proved, and if this splendid province should ever be opened up, fortunes will yet be made in this branch of mining."

In his description of the coal-fields of the Naga Hills, published in 1876,\* Mr. Mallet enumerated the places where oil has been observed in this district, and the approximate positions of these springs or surface indications are shown in the sketch map of the Assam oil-field (Fig. V.). In all cases the oil rises either on or close to the outcrop of the coal-bearing group, and usually near the outcrop of one or more seams of coal; indeed, Mr. Mallet records one instance in which he saw the oil oozing out of the coal itself, though he points out that this may have been accidental, the coal being merely the last rock through which the oil passed on its way to the surface. Thick soft

sandstone is the rock principally met with in boring, but blue clay also occurs. The strata, which are much disturbed, belong to the tertiary epoch.

The most likely sites for productive wells appear to lie within the area of the immense concessions granted to the Assam Railways and Trading Company, and it is well known that this company has for some time past been drilling at Digboi (see Fig. V.).

Mr. J. B. White, a director of the company, has just returned to this country from a visit to Assam, and has very courteously given me full information as to the drilling operations. Digboi is situated six or eight miles to the west of Makum, and drilling was commenced here last autumn, the spot having been selected on account of the good surface indications. At a depth of 176 ft. oil and gas were met with in soft sandstone (subsequently found to be immediately overlying shale), and it was anticipated that the well might yield as much as 80 barrels per day. The production however rapidly diminished, and it became evident that the oil occurred in a small "pocket" which was soon emptied. Drilling was accordingly recommenced, and the well is now in process of being deepened. The indications are regarded by the driller as exceedingly promising, but drilling is here, as elsewhere in India, difficult, and there is considerable tendency to "caving." The oil from this well is, in Mr. White's opinion, less viscous than that obtained at Makum, and contains more paraffin, a large amount of solid hydrocarbons separating from it at 38° F., which was the minimum temperature during his stay. I hope shortly to give the results of an examination of this oil. Mr. White, who was concerned in the work carried out by Mr. Goodenough, informs me that the official accounts from which I have quoted under-stated the yield of the wells. From one bore there was a continuous flow for 18 months after the project was abandoned. He adds that surface indications of oil occur over an area some 60 miles square, and in places the soil is so saturated with petroleum that it is sold for use in protecting timber from the attacks of the white ant.

Mr. R. A. Townsend has recently made an official report\* upon the Assam oil-field which is in the main confirmatory of the foregoing statements. Mr. Townsend's visit of inspection was made in the wet season, and therefore in some respects under conditions unfavourable to accurate observations; but he appears to have satisfied himself that the prospects of success in boring for oil in Assam are extremely good, and he points out that to a large extent the difficulty of transport has been removed.

On more than one occasion within the past 12 years I have examined samples of Assam crude petroleum. The oil, as will be seen from a sample on the table, is dark brown in colour, of rather high viscosity (the viscosity of a sample of sp. gr. .940 was 14.2 at 90° F., rape oil at 60° = 100), and has a slight and not unpleasant odour. Its specific gravity appears usually to range from .933 to .940, and its flashing point is sometimes as high as 212° F. (Abel test). It begins to distil freely at 280° F., but considerably less than 20 per cent. volatilises within the range of the mercurial thermometer. The oil contains none of the kerosene hydrocarbons, but it yields by the ordinary process of distillation 89 per cent. by weight of lubricating oil distillates. The proportion of solid hydrocarbons is not large. The carbonaceous residue varies, according to my experiments, from between 3 and 4 per cent. to over 8 per cent.

In the paper by Mr. Hughes already referred to, particulars are given of the examination of a sample of the Assam crude oil. The material had a specific gravity of .971, and commenced to boil at 460° F.; it was therefore of greater density than the samples I have distilled, but it appears to have yielded more paraffin. As, however, a series of the distillates obtained, ranging in specific gravity from .873 to .918, are characterised as suitable for lamp oil, "although of rather higher specific gravity than that obtained from American petroleum," I do not consider the results worthy of much consideration.

### 3. PUNJAB.

Accounts of the Punjab oil-springs were published by Mr. A. Fleming in 1848\* and in 1853;† by Mr. MacLagan in 1862‡ and by Mr. A. Fenner in 1866.§

A few years later Mr. Lyman was deputed to examine the deposits, and his reports were issued collectively in 1871.¶ From these it appears that in the Rawalpindi district (see Fig. 1.) there are some 16 spots at which indications of petroleum are met with in the tertiary rocks.

Mr. Lyman states that in every case the oil seems to come from a deposit of very small horizontal extent, "sometimes only a few feet, seldom as much as a few hundred yards." Some of the natural springs are described as yielding "as much as three quarts per day," and a boring of 75 ft. deep at Gunda is asserted to have produced about 11 gallons of oil a day for a period of six months. Mr. Lyman gives the density of the oil as 25° B. (=907), but there appears to be some variation in the quality of the oil, for while that obtained at Gunda is said to be burned by the natives "with a simple wick resting on the side of an open dish," the product of the Pannolia springs is described as being more inflammable, and as needing a tube for the wick.

Mr. John D. Noble, of Petrolia, a well-known Canadian petroleum producer and refiner, recently spent some time in this district, and thinks so highly of the prospects of establishing a successful petroleum industry in the Punjab that he has secured a concession of a large extent of territory with a view to drilling for oil.

### 4. BALUCHISTAN.

The oil-field of Khātan is situated in the Mari Hills of Baluchistan, about 40 miles in a direct line to the east of Sibi station on the Quetta branch of the North-Western Railway running from Ruk junction to Quetta. The position of the petroleum wells is shown on the sketch-map of India (Fig. 1.).

The oil occurs in the Eocene formation, and is found exuding in many places, much of the oil which has thus escaped having been converted by exposure into a hard mass.

Borings were first made here on behalf of the Indian Government by Mr. R. A. Townsend, Superintendent of Petroleum Explorations, in the cold season of 1884—85, and it was found that immense quantities of petroleum were obtainable at moderate depths. The wells drilled by Mr. Townsend are five in number, and are situated in a valley surrounded by mountains about 4,000 ft. high. Their diameter is only 4½ in., and their depth does not much exceed 500 ft. The geological features of the locality have been carefully dealt with by Mr. Townsend in an official report,¶ and the section reproduced from that document (see Fig. VI.) clearly indicates the character and disposition of the strata.

The following is an explanation of the section:—

- 1, 2, 3, 4. Nummulitic limestone.
- 5, 7, 9, 11, 13, 15. Light-brown earthy limestone, interstratified with clay and shale and (in 6, 8, 10) gypsum.
- 8 consists of a massive stratum of pure white gypsum.
- 16, 18, 20, 22, 24. Chunchy limestone, interstratified with soft shale.
- 25, 27, 29, 31. Soft olive shale.
- 26, 28, 30. Dark brown flint.
32. Fine-grained hard blue limestone.

"It is in the two deposits of shale 25 and 27 that the first traces of petroleum are discovered, and in several places where vertical faces are exposed to the direct sun's

rays, bituminous drops and threads mark them with a jet blackness."

The following record of one of the borings, of 524 ft. in depth, indicates the order of succession downwards of the strata perforated by the drill:—

	Thickness.	Depth.
	Feet.	Feet.
(1.) Gravel, with boulders and bitumen..	12	12
(2.) Jointed blue limestone .....	20	32
(3.) Hard, marine conglomerate, with abundance of flint .....	195	27
(4.) Alternating bands of soft, bluish shales and hard flinty limestone with iron pyrites.....	30	257
(5.) Rather hard shale with pyrites.....	217	474
(6.) Dark grey limestone without fossils..	2	476
(7.) Soft grey shales.....	48	524

Oil was obtained at 28, at 62, at 92, at 115, at 125, at 133, and at 374 ft. Mr. Townsend states that, "both in drilling and pumping, a considerable quantity of sulphuretted hydrogen gas escapes, but it is not in sufficient quantities to cause a natural flow of oil from the tubes."

Owing to the disturbed character of the strata, drilling is extremely difficult; the conglomerate is fractured in all directions, and through the fissures "the oil finds its way upwards, borne on the top of the warm waters which accompany it; but while these fractures afford a ready means to the miner of 'striking oil,' they sadly interfere with his progress in boring, as the drilling tool in descending must inevitably enter many of these crevices at an acute angle to their planes, and it is almost impossible to prevent the tendency of the tool to follow the vagaries of such crevices, and thus produce a 'crooked hole,' which is fatal to further progress, unless straightened."

Unfortunately the oil obtained is of remarkably high specific gravity and viscosity, as will be seen from the sample on the table. Its density is, I find, practically identical with that of water, and it is in consequence freed with very great difficulty from the water with which it is associated as it comes from the well. Even when the oil is warmed the water does not readily subside. If an attempt be made to distil the oil containing water, the contents of the still froths up and passes over bodily. By prolonged exposure in a capacious vessel to a temperature somewhat above the boiling-point of water, the oil can be sufficiently dehydrated, but a far better system has been suggested, which I hope before long to have the opportunity of describing. The oil is black or extremely dark brown in colour by transmitted light, with comparatively little fluorescence, and it possesses very little odour. Its flashing point is 280° F. (Abel test), and it contains no hydrocarbons available for use as ordinary burning oil. If 50 per cent. be distilled off, the first third of the product will be found to have a specific gravity of about .910, and the remaining two-thirds of about .930, but the viscosity of these distillates is extraordinarily low in relation to the specific gravity. By careful distillation with superheated steam, about one-fourth of the product (one-eighth of the crude oil) may, however, be obtained of sp. gr. .958 and viscosity 168 at 70° F. (rape oil at 60° F. = 100). This oil would be available for use as a lubricant. The residue in the still, when 50 per cent. of the volatile matters have been removed, forms on cooling a moderately hard pitch of jet black colour and lustrous fracture, as the specimens before you indicate. This material might be employed in the manufacture of "patent fuel" and for other purposes. When distilled to dryness the crude petroleum yields rather more than 70 per cent. by volume of a heavy oil containing very little paraffin, and the residue then consists of about 26 per cent. by weight of hard coke. The last portions of the distillate when exposed to a temperature of 32° F. assume the consistence and appearance of vaseline.

Khátan petroleum is by far the most refractory oil to which Professor Dewar and I have applied our new process of distillation, but we have succeeded in obtaining from it about 40 per cent. of kerosene, which has a specific gravity of .810.

It is, however, as a fuel for use in locomotives and otherwise that the petroleum in question is likely to become specially valuable, and from this point of view the importance which attaches to the development of the Khátan oil-field is very great. On a former occasion\* I have referred to the extent to which liquid fuel is employed in Russia, and I anticipate that in those districts of India where solid fuel is very costly, as is the case in Baluchistan, we shall before long see this example followed. The Khátan oil-field lies at an elevation of 1,400 to 1,500 ft. above the railway at Sibi, and it has been proposed to transport the oil to the railway by pipe-line; but as I have already said, the oil is very viscous, and experiments made led to the apprehension that great difficulty would be experienced in pumping it. Mr. Townsend is of opinion that the oil might be pumped so long as its temperature did not fall below 70° to 80° F., but at certain seasons of the year it would be exposed to a temperature far below that. About two years ago I had occasion to investigate the subject, and I found that the viscosity of the oil at 85° F. was no less than 430 times that of ordinary Baku crude petroleum, the viscosity of which is 11.6 at 90° F. (rape oil at 60° F. = 100); I, however, arrived at the conclusion that by the employment of a pipe-line of large diameter, with a sufficient number of pumping stations and powerful pumps, the oil could be transported during at any rate the greater part of the year. The consistence of the oil is not due to the presence of a high percentage of solid hydrocarbons as is the case with much of the Yenangyoung oil, but arises from the large amount of asphaltum present. Hence the fluidity of the oil is not very largely increased by a moderate elevation of temperature.

As an alternative scheme to the pipe-line it has been proposed to connect Khátan with the Sind-Pishin State Railway at Babar-Kuch, and thus provide a means for the transport of the oil, but such a line would be very costly owing to the difficulties of the country through which it would pass.

Mr. Townsend, with whom I had some conversation during his recent visit to this country, evidently appreciates fully the importance of the fuel question, but he regards the comparatively inaccessible position of the field and the trying character of the climate during the hot season (when no European could work there) as serious obstacles to the utilisation of the Khátan petroleum deposits. That petroleum may be obtained there in apparently immense quantities is clearly shown by the yield of the wells. According to the official report of Colonel Conway-Gordon† experiments made by pumping four of the wells (the fifth had not then been drilled) showed that the yield of each well was from 400 to 600 barrels of oil in the 24 hours. "Thus any one of the existing wells is more than competent to deliver the entire supply of 50,000 barrels of oil a year, which is estimated to be the amount required for the Sind-Pishin section of the North-Western Railway."

In this connection I may perhaps be permitted to reproduce the following extract from the "Indian Engineer," which was published last year in the Journal of this Society,‡ under the erroneous heading of "Petroleum works in the Punjab":—"The Khátan petroleum works have, it appears, now passed beyond the experimental stage. An agreement has been definitely entered into to supply the works at the Khojak tunnel with about 3½ million gallons of the oil. The wells, which are 42 miles from the railway, have been connected with Babar-Kuch on the Sind-Pishin line. The saving to the State from the use of the petroleum on the Khojak works alone will, it is estimated, be enough to cover all the cost of the Khátan experiments, and leave a balance of over 5 lakhs of rupees,

† Administration Report on the Railways of India for 1887-88, by L. Conway-Gordon, Lieut.-Col., R.E., Director-General of Railways.

‡ 1889, 314 (Trade Report).

And there is no reason to anticipate that the benefits of the apparently inexhaustible supply should end here. On the contrary, in a country like Beluchistan, where every stick of wood is worth its weight in silver, the demand for the new fuel must be very great; and in addition to other advantages its use may be expected to put a stop to the destruction of the forests, which until recently was going on at an alarming rate. It is now intended to replace the expensive and wasteful system of camel carriage by laying a pipe-line from the wells along the Babar-Kuch road; and should Government decide on sanctioning this, it may be confidently expected that the capabilities of Khātan will emerge once for all from the cold shade of neglect and scepticism in which an exaggerated idea of its remoteness has left it so long."

An oil similar to that obtained at Khātan occurs at Shoran, in Kalat, in the province of Kach Gandawa, in Hind Baluch country. Shoran is about 42 miles from the railway at Belpat, and it is a question which of the two fields it would be best to develop for fuel purposes.

#### GENERAL CONCLUSIONS.

Throughout India, petroleum occurs in the tertiary formation, as in Russia and Galicia. The strata in the oil-producing localities are greatly disturbed, and drilling is everywhere in India more or less difficult.

Apparently petroleum occurs in the greatest abundance in the Khātan oil-field in Baluchistan, but the oil is not of satisfactory quality even regarded as liquid fuel, the locality of production is comparatively inaccessible, and the climate is bad.

Undoubtedly the best oil from the point of view of the kerosene refiner is that which is obtained in the Arakan islands (the eastern Baranga and Ranni). On the other hand, the Yenangyoung oil, or much of it, though not yielding kerosene largely by the ordinary process of manufacture, contains much paraffin, which is a valuable product, and, as has been pointed out, the yield of kerosene from such oil is capable of being largely increased.

As regards geographical position, the Arakan deposits are placed at an advantage over those of Upper Burma, and in like manner the Upper Burma deposits, or most of them, can be developed more advantageously than those of Assam, in consequence of the transport facilities afforded by the Irrawaddy river.

Far too little is known about the oil-fields of India to admit of a confident prediction as to their future, in respect either to area or to potential productiveness, being uttered. Even as regards Upper Burma, we cannot say whether the future centre of most successful development will be Yenangyoung, Pagan, Minbu, or elsewhere, and the actual results of drilling can alone remove the uncertainty at present existing. Moreover, it by no means follows that the precise spots selected by the natives as giving readiest access to the oil through the primitive methods of working available to them will prove to be the most productive ones when the drill is substituted for the spade.

The Indian Government appear disposed to encourage competitive private enterprise, especially in the oil-fields of Upper Burma, and so long as this principle is legitimately applied no exception can be taken to it; but in the interests of the Empire it is to be hoped that the work of petroleum exploration and development will in no case be attempted without a full appreciation of all that it involves. It is in the highest degree important that this work should for some time to come be carried out under skilful, energetic, and above all, experienced management, and that ample means should be provided. On any other basis it is highly probable that much money would be wasted without obtaining satisfactory results, or even conclusive negative evidence; much disappointment and discouragement would ensue, and the development of the oil-fields of India would be considerably retarded.

Hitherto the practice of the Government has been to grant a prospecting licence for a period of 12 months over four square miles of territory. On the expiration of the specified period the licensee is at liberty to select one square mile, over which he has the right to drill for oil, on the basis of

the payment of a royalty of 20 per cent. on the oil raised. It is now, however, reported from Rangoon that the Government has decided to grant no more prospecting licences or concessions, at any rate in the Yenangyoung district, and that as soon as Dr. Noetting has completed the marking out of the oil-bearing lands in this locality into square mile blocks, these will be offered for sale by auction. The necessity for purchase should afford some guarantee for the work of development being efficiently carried out.

I am indebted to the India Office, and especially to Mr. Arthur N. Wollaston, C.I.E., for affording me exceptional facilities in referring to various reports dealing with the subject of this paper.

### AN INSTRUMENT FOR THE MEASUREMENT OF DIFFUSE DAYLIGHT AND THE ACTINOGRAPH.

BY F. HURTER, PH.D.

THE actinometer which I have devised for measuring diffuse daylight depends upon entirely different principles than the instrument Mr. Ballard has just brought to our notice. In most instruments designed for measuring light the eye has to decide when two things are equal, in Mr. Ballard's instrument, when the luminosity of the paint is equal to the light coming through the blue glass, in the ordinary silver paper actinometers the eye decides when two tints are equal.

Once when examining the spectrum of nitric dioxide the thought struck me that the light absorbed by that gas must do some molecular work, and as this was not chemical

decomposition, it could only result in a rise of temperature. I saw the application which could be made of this, and I found that if a differential gas thermometer was filled with nitrogen dioxide, one bulb exposed to diffuse light, the other kept in the dark, the gas exposed to the light expanded. But owing to the difficulty of finding a suitable separating fluid, one which should not absorb the gas, I could not obtain satisfactory results. Equally unsatisfactory I found an instrument filled with bromine vapours. The idea that all coloured substances would in diffuse light assume a slightly higher temperature than white or colourless transparent substances led to the construction of differential thermometers, the bulbs of which contained a red substance in one, and a white one in the other. Very sensitive instruments were obtained with red and white wool, next in sensitiveness was cotton and paper. The red substances absorb most of the rays of the spectrum, except the red ones, whereas the white substances absorb very little of any of the rays, and the absorption of the light causes a slight rise in the temperature of the red substance, which expands the air of the bulb containing this substance. The consequent increase in pressure is read off on the scale behind the syphon gauge, and as experiments in this direction proved, this rise of pressure was proportional to the chemical action of the light on silver salts.

But instruments so made were very unsatisfactory. Beside the temporary alterations in pressure in the bulb containing the red substance there was also a permanent change, which increased with every exposure to the light, and though little perceptible in one day, in the course of a few months became so large as to completely destroy the

instrument by driving the liquid out of the syphon gauge into the bulb containing the white substance.

An investigation of what this was due to revealed the fact that the oxygen of the enclosed air gradually vanished, and it disappeared faster in the white tube than in the red one. What becomes of the oxygen I am unable to say. It was clear I had to abandon organic substances.

But even when I began to use coloured glass the same difficulty still arose. I used either alcoholic solutions or benzine solutions of alkanet as indicator in the syphon gauge, and even after I had abandoned them also I still found the zero points of the instrument unsteady. It varied very little, but in the course of a year the change was quite perceptible.

A good instrument can however be made as follows:—Two test tubes holding from 10 to 15 cc. are chosen; one of them must be made of very thin glass flashed inside with copper ruby glass, the other one must be of similar thin clear white glass. They should both be of the same weight and the same capacity, a slightly larger capacity for the white tube is favourable. These tubes must be well cleaned with nitric acid and caustic potash, carefully rinsed with boiled distilled water, dried and fused on to capillary glass tubes. When this has been done they must be repeatedly exhausted under the air pump to remove all products of combustion which enter during the operation of fusing to the capillary. They are finally made red hot and when cool a single drop of pure distilled water is allowed to enter into each tube, and is shaken into the bulb. The syphon gauge is filled either with a solution of potassium bichromate, or better with a solution of potassium carbonate, to which is

#### HURTER'S ACTINOMETER.

Back View.

Front View.

added sufficient potassium iodide and iodine to give it a deep colour. The bulbs are then sealed on to the syphon gauge, two very fine hair tubes being drawn out first, through which the air can escape and enter, on either side of the liquid in the syphon gauge.

When the instrument is so far completed it is again exhausted repeatedly to remove products of combustion, and the hair tubes are sealed up, the bulbs being at the time immersed in cold water to keep their temperature alike. The instrument has then to be tested to see that it is absolutely air-tight, and that both bulbs behave alike when the temperature is raised.

The position of the liquid in the gauge must not move under the receiver of the air pump, nor when the bulbs are immersed in hot water. A temporary change during the latter operation always occurs, but it must be only temporary.

If the instrument be found good it is mounted in a wooden box with a glass front, and to render it more sensitive the bulbs are placed in front of two concave reflectors, which are best made of silvered sheet copper and very thin. The side of the box opposite the reflectors is closed by a sheet of thick patent plate glass, coated on the outside with transparent gelatin and varnish, which helps to prevent the entrance of heat rays into the box.

A millimetre scale behind the syphon gauge, which is outside the box at the back, completes the instrument. (See illustrations.)

Yellowish-brown glass is almost as good as ruby glass and easier to procure.

An instrument of this description will indicate the brightest diffuse daylight obtainable in this country, as reflected by the northern sky by a variation in the level of the liquid of about 80 millimetres. It is therefore possible to measure the diffuse light to one per cent. of its greatest intensity with ease, and this is more than sufficiently accurate for all photographic processes.

By means of this instrument it is quite possible in steady light to time very accurately the exposure of a photographic plate. But my friend Mr. Driffield soon discovered that a very accurate measurement of the light was not necessary, and the reason for this we decided to ascertain, and he has been my fellow worker in all subsequent investigations.

We made self-recording actinometers by registering the position of the liquid in the syphon gauge photographically

upon gelatino-bromide paper, which was fastened on a revolving drum driven by a clock. We continued to take observations for every day of the year 1885—86, and some of these photographs of the intensity of diffuse daylight are represented by the diagrams.

When there was a steady light throughout the day, which seldom occurred, the curve so clearly indicated that the light was a function of the altitude of the sun, that I had no difficulty in recognising the sinus curve. This curve showed itself really in almost every diagram. It is broken up by passing clouds. The dotted curve in the diagram of March 4th shows the sinus of the altitude of the sun on that day for latitude  $53^{\circ} 8'$ . By measuring at the same time the diffuse light with the actinometer, and the sinus of the altitude of the sun by well-known means, we obtained the connexion between the altitude of the sun and the degrees of our actinometer.

We thus found that the diffuse light at any given hour of any given day is seldom less than 25 per cent. of the maximum light possible at that hour, except when it is foggy or raining, but under those circumstances no one thinks of taking pictures outside.

It is therefore clear that exposures of photographic plates at any particular moment under ordinary conditions vary only in the ratio 1:4. But as other investigations which Mr. Driffield and myself made showed that the latitude of exposure within which a good picture is possible is in many cases comprised in exposures varying from 1:2, it will be seen that accurate measure of the light is quite unnecessary.

We therefore together devised the little instrument called the actinograph, which Mr. Ballard recommended as a calculating machine. The fact is, it is not only a calculating machine, it is in reality a machine for telling at any hour of the year the maximum light possible, and for converting that indication directly into times of exposures of plates of varying speed, with various lenses.

The manipulation of the instrument is exceedingly simple, and it has this great advantage over actinometers, it tells beforehand what the exposure on any day at any hour has to be, according to the condition of the atmosphere, and the eye soon judges that. With this instrument photographic exposures can be ascertained with so great a degree of probability as to be almost equal to certainty.

DIFFUSE LIGHT REGISTERED BY HUYTER'S ACTINOMETER.

March 4th, 1886.

June 12th, 1886.

The instrument has four scales: a light scale on a revolving cylinder, a slide carries the lens scale and the time scale, and on a fixed scale is marked the speed of the plate. The speed of the plate must be ascertained by the operator by a simple experiment.

The lens scale is set to the hour and date at which an exposure is to be made, the speed index is set to indicate the speed of the plate; when that is done five different exposures in seconds can be read off at once, corresponding to five different conditions of the light: Very bright, bright, mean, dull, and very dull.

The sketch shows the instrument.

THE ACTINOGRAPH.

To give an idea of speed, I will add that Wratten's slow plates are about 10 on our scale, and Ilford Ordinary about 15 to 20.

The degree of light and the unit of speed are chosen for the instrument as follows:—The highest possible diffuse light corresponding to the altitude of the sun =  $90^\circ$ , is divided into 100 equal parts, one of which we call an actinograph degree. The unit of speed is the speed of a plate which with one such degree of light will take an ordinary landscape in as many seconds as the square of the ratio of the focal length and aperture indicates. Thus a plate would be speed 1, which with one actinograph degree of light, and a lens of  $F \div 4$  it would take 16 seconds to produce a good landscape negative.

This system of degrees of light and speed of plates I venture to say is the only scientific one which has yet been proposed, and the actinometer I have described I believe to be the only satisfactory instrument for measuring diffuse light yet devised. The photographed records show that it is somewhat slow in following the light. Indeed the variations of light are frequently so sudden that the use of actinometers for photographic purposes will always remain unsatisfactory, because some time must necessarily elapse between the observation of the light and the exposure owing to a calculation having to be made.

The actinograph, on the other hand, avoids all calculation, takes into account variations in light, in lenses, and in plates, and will be a truly scientific substitute for actinometers, so long as the earth does not deviate from her time-honoured journey round the sun.

## NOTE ON A CRYSTALLINE BOILER DEPOSIT.

BY A. F. FRYER,

*Sheridan-Muspratt Scholar, University College, Liverpool.*

A few weeks ago, on the removal of a boiler from a steam tug, which had been working in the River Mersey some 12 years, an interesting deposit was found, especially incrusting the iron stays of the boiler. A sample of this was kindly sent to our laboratories by Mr. T. L. Miller.

It was thought that the sample would be worthy of your interest, on account of the thickness and the convoluted appearance of its upper surface, but especially because the greater part of it is distinctly crystalline.

The substance consists almost entirely of the sulphates of calcium and magnesium, as will be shown by the percentages of my analysis:—

CaO .....	33.3
MgO .....	7.3
Al <sub>2</sub> O <sub>3</sub> .....	1.4
SO <sub>3</sub> .....	51.7
SiO <sub>2</sub> .....	0.6
Moisture .....	2.6
	<hr/> 96.9

There is also a trace of iron and the faintest trace of chloride.

The presence of the water is, I think, interesting. The sulphate of magnesia is undoubtedly present as kieserite, which crystallises with one molecule of water. The percentage of water necessary for my 7.3 per cent. of magnesia would be 3.3 per cent., which you see is a little above the actual amount found.

From an examination of the crystals, they appear to consist of the rhombic anhydrite  $\text{CaSO}_4$ , along with a little kieserite.

The specific gravity I also determined and found to be 3.05 (that of anhydrite is 2.8—3.0).

Hoppe-Seyler and G. Rose have shown that gypsum when strongly heated in a solution of sodium chloride is converted into anhydrite. The conditions under which this deposit has accumulated point to the probability that its crystalline structure may have arisen from this cause. It is curious also that at Stassfurt anhydrite crystals occur in the kieserite, crystallising in rhombic prisms with pinnakoid domes. 8.6 per cent. of the substance is soluble in water, and the calcium sulphate is more soluble than the magnesium sulphate, the proportions being 88.71 per cent. to 11.29 per cent. respectively.

No alumina was found in the soluble portion.

## DISCUSSION.

Dr. Kohn said it would be interesting to hear if any of the members had come across a very marked crystalline boiler incrustation, similar to the one shown.

Mr. W. P. THOMPSON said it was very rarely that they did not find the deposit crystallised when it was largely sulphate of lime. He had repeatedly had to clean out boilers in his younger days, and he had repeatedly seen the stuff crystallised when it had plenty of sulphate of lime. He had seen the crystals with  $\frac{1}{4}$  in. long needles when they were at the end of a nut or stay. They were found in locomotive boilers in the form of radiating nodules.

Dr. HERTER said that as a rule boiler incrustation was always of a crystalline texture, but he had never seen such beautiful specimens as those shown.

MR. R. R. TATLOCK IN THE CHAIR.

## NOTE ON THE FATTY ACIDS OF OLIVE AND OTHER OILS.

BY ROBERT R. TATLOCK, F.R.S.E., F.I.C., F.C.S.

IN estimating the fatty acids in olive-oil soap I have always and very frequently noticed that after the acids were dried till every trace of water had been expelled they continued to lose weight by exposure to the temperature of the water-oven, which is usually about 90° C. (194° F.). That this loss resulted from the volatilisation of some substance, probably of an acid character, which had been in combination with soda, there could be little doubt, and subsequent experiments confirmed this view. In any case the substance dissipated was not water, and as its amount was considerable the question arose as to whether it should be regarded as a portion of the fatty acids, or merely as an inoperative substance incapable, even in combination with soda, of contributing to the detergent properties of the soap, and consequently of little or no value. At first it was thought probable that this volatile body existed only in the oil which had been extracted from the olives by chemical means or solvents (disulphide of carbon), and which is commonly employed for the manufacture of this class of soap, and that it would not be present in the oil expressed by mechanical means. It was soon found by experiment, however, that it existed in these two varieties to an equal extent as nearly as possible. On extending the investigation to other oils I soon found that while the fatty acids of some of these behaved in a similar manner to those of olive oil—giving off a volatile body at or under steam heat—there were other oils whose acids gave an opposite result, as they gained weight, undoubtedly due to oxidation, under similar circumstances, as did olive oil itself, and more particularly when it was deprived of the considerable proportion of free oleic acid almost invariably present in the commercial article. Of course it is quite possible—indeed highly probable—in the case of fatty acids of olive oil and those which behave under heat in a similar manner, that oxidation and consequent increase of weight goes on simultaneously with volatilisation and consequent decrease of weight, but that the latter goes on at a greater rate than the former, thus making it alone apparent. On the other hand it is hardly possible that the fatty acids such as stearic, that show but a slight decrease in weight after many hours' exposure, can contain any appreciable proportion of volatile substance, as if they did it would pass off at any early stage of the heating process, at least to a large extent, and would thus be observed.

The subjoined table shows the weights of 100 parts of fatty acids from various kinds of commercial olive oil, as well as those from castor, rape, cotton-seed, linseed, and stearine, and also of commercial and neutral olive oil, when exposed for various periods to a temperature of 90° C. (194° F.).

The fatty acids were in each case prepared by saponification with alcoholic potash and liberation by normal hydrochloric acid in slight excess. They were then dried until they ceased rapidly to lose weight, and no film of water could be condensed on glass by the cooling of their vapours.

It is unnecessary to interpret the results, as the figures speak so plainly for themselves. It should be noted, however, that the olive oil No. 10 was the one employed to produce the fatty acid No. 4 as well as the neutral oil No. 11, which was obtained by shaking up the oil with weak solution of caustic potash to saponify the free fatty acid, dissolving out the neutral oil by ether and recovering by evaporation.

Of course the volatile substance may be a decomposition-product of the fatty acid from which it is evolved by heat,

and judging from the tardiness with which its evolution begins and progresses, it is more likely to be such than a volatile acid pre-existing in the oil. On account of this consideration I have hitherto in analysis of soaps and oils returned it as a portion of the true fatty acid.

It is obvious from these results that the determination of fatty acids in soaps is, in many instances, a delicate operation, and one requiring as much care, skill, and observation as any other part of the analysis of that material.

#### DISCUSSION.

MR. STANFORD asked what acid was used in precipitation? His reason for asking that was because he had found it extremely difficult to wash some organic substances free from acid, and he thought it was possible some acid might have been left and become a little concentrated. He was also inclined to think there might be a small portion of glycerin left. With regard to the loss of about 8 per cent. that occurred, it seemed to him that the volatile substance might be recovered, and he hoped Mr. Tatlock would try and devise some method for doing so.

DR. MILNE asked Mr. Tatlock if he had not employed sulphuric acid as well as hydrochloric in precipitation?

MR. TATLOCK, in reply, said that the first three or four results were got by the use of sulphuric acid, but in the later experiments hydrochloric acid was considered to be the best. With reference to Mr. Stanford's suggestion about some of the acid being left, he should have said in his paper that the hydrochloric acid was added in very slight excess, so that the volatile substance got amounted to very many times the entire excess of acid employed. As regarded glycerin being left, considering the complete saponification with alcoholic potash, he was of opinion the glycerin must all have been washed away.

to manipulate, which is a serious matter in a works laboratory where many analyses have daily to be made.

It must be admitted that outside of those directly connected with the subject, very few even competent chemists will be found from whom reliable results can be obtained. There is evidence of this in a case which came before my notice some time ago, in which a sample of cobalt material agreed upon by the buyer and seller at 6 per cent. was reported by a competent French chemist to contain 15 per cent. This is certainly an exaggerated instance, but there is doubtless necessity for more light being thrown on this subject, and I think I am justified in putting on record a complete process for the separation and estimation of cobalt and nickel, which, although not quite new, may still be unknown to the majority of the members of this Society.

The process consists of two operations:—

1. Separation and determination of the cobalt by the "phosphate" method.

2. Determination of the nickel by electrolysis.

The "phosphate" method was originally devised by M. Dirvell, and published in 1879, but, as then described, proved very unworkable, and it was not until modified on several important points by Dr. Clark in 1883 that its value as a means of separation was really appreciated. It has now been in daily use for several years, and has given complete satisfaction both as to accuracy and the facility with which the separation can be made.

Before proceeding to its description it may be well to describe briefly the procedure usually adopted leading up to the separation which is applicable to ores and mattes containing metals removable by  $H_2S$  in acid solution, and any iron, alumina, or manganese which may be present. A quantity of the sample is taken according to its approximate contents, but that will be found most suitable which gives about .5 gm. or thereabouts of mixed metals. This is dissolved in  $HCl$  or aqua regia and evaporated to dryness, the residue moistened with  $HCl$ , dissolved in hot water, filtered from silica, &c., and in the filtrate metals of the second group are removed with  $H_2S$ . After oxidation with  $HNO_3$  the filtrate is nearly neutralised with  $Na_2CO_3$ , and the iron and alumina twice precipitated with acetate of soda to ensure perfect separation. The mixed filtrates, thoroughly freed from iron and alumina, are slightly acidified with acetic acid, and the cobalt and nickel thrown down with  $H_2S$  gas, filtered, washed with  $H_2S$  water, dried, calcined, and weighed as a guide to the approximate quantity of the two metals present.

#### THE ESTIMATION OF COBALT AND NICKEL.

BY JAMES HOPE.

THE separation of cobalt from nickel has always been a matter of difficulty to the chemist, especially due perhaps to the extremely analogous properties of these two metals.

Many processes, however, have been devised for this purpose, but the majority have been abandoned as being in various respects faulty. The "nitrite" process, which is that most commonly recommended by text-books, is no doubt found by some to give fairly good results, but in the hands of inexperienced operators very often fails to give any results at all when cobalt is certainly known to be present. The chief objection, however, is that it is long and tedious

The cobalt and nickel being thus obtained as sulphides and free from all other metals, are dissolved in aqua regia in a small covered beaker, any sulphur which may separate being removed by heating with a few drops of bromine, and the solution evaporated to dryness with the addition of a few drops of dilute  $\text{H}_2\text{SO}_4$  to convert the metals into sulphates. The presence of chlorides would interfere with the subsequent electrolysis of the nickel. The residue after dissolving in hot water and diluting to about 50 cc. is then ready for the separation. A quantity of phosphate of ammonia ( $\text{NH}_4\text{H}_2\text{PO}_4$  containing about 61 per cent.  $\text{P}_2\text{O}_5$ ) equal to about four times the weight of metallic cobalt and nickel present, is now weighed off, dissolved in the smallest possible quantity of water and boiled for a minute or two with a few cc. dilute  $\text{H}_2\text{SO}_4$ . This is afterwards added to the solution containing the cobalt and nickel which has been previously heated nearly to boiling.

Dilute ammonia (2 parts '880 to 1 of water) is now cautiously added until the light blue precipitate which at first forms partially dissolves, and finally with constant stirring and addition of the ammonia drop by drop the cobalt comes down as a pink crystalline precipitate of ammonio-cobaltic-phosphate  $\text{CoNH}_4\text{PO}_4$ . The beaker is placed on the top of the water-bath for 5 or 10 minutes with occasional stirring and finally allowed to settle. The clear blue filtrate containing the nickel is decanted off through a small filter, and the precipitate in the beaker dissolved in a few drops dilute  $\text{H}_2\text{SO}_4$ ; a small excess of phosphate of ammonia again added and the cobalt reprecipitated with ammonia exactly as already described. The precipitate is now transferred to the filter, washed well with small quantities of hot water, and dried at  $100^\circ\text{C}$ . After removal of the precipitate the filter is burned in a platinum capsule, the precipitate added and ignited for 15 or 20 minutes over a good Bunsen burner. The ammonio-cobaltic-phosphate is thereby converted into the purple coloured pyrophosphate  $\text{Co}_2\text{P}_2\text{O}_7$ , and as such is weighed, the metallic cobalt being found by multiplying the weight obtained by the factor (0.403).

In many cases the reprecipitation of the cobalt might be dispensed with, but it is absolutely necessary where the nickel is largely in excess of the cobalt. As it only occupies a few minutes it is always safer in every case to make the second precipitation to ensure perfect separation.

The proper quantity of ammonia to be added is also a point which requires careful attention, as an insufficiency would still leave nickel with the cobalt, and too large an excess would likely dissolve a little of the cobalt. Before proceeding therefore to the estimation of the nickel, it is customary to examine the mixed filtrates by gently heating for a few minutes on a sand-bath, and if a slight pink precipitate forms it is immediately filtered off and added to the main precipitate. Cobalt, however, is rarely found with the nickel as, with careful observation, the exact point at which the addition of the ammonia should be stopped is easily discerned. Prolonged heating of the nickel filtrate when free from cobalt might precipitate a small quantity of the nickel as the yellow-coloured phosphate. This may be easily removed by acidifying with  $\text{H}_2\text{SO}_4$  and making again alkaline with ammonia.

The clear blue filtrate now ready for the determination of nickel is contained in a tall form of beaker, and should bulk about 200 cc. About 10 cc. strong ammonia are added, to render distinctly alkaline, and the solution, after heating to about  $70^\circ\text{C}$ ., is immediately ready to be electrolysed. For this purpose a battery of two 1½-pint size Bunsen cells is found to give the requisite strength of current, and is capable of depositing about 0.15 to 0.20 grm. of nickel per hour.

The electrodes employed consist of a sheet of platinum shaped in the form of a cone, to the side of which a piece of thick platinum wire is riveted, and a spiral formed of the same kind of wire terminating in a straight piece, both being of the dimensions usually supplied by Johnson, Matthey, and Co., of London.

The spiral being now inserted in the solution, the cone is also suspended to cover, without touching, the spiral, taking care to have it wholly immersed in the solution. The battery can now be connected, the cone with the zinc or negative

pole and the spiral with the carbon or positive pole, and the beaker covered with two halves of a watch glass. If the battery is in good working order, the nickel will be found firmly deposited on the cone as a bright metallic coating in from two to three hours. The complete deposition of the nickel may easily be ascertained by drawing off a few cc.'s of the solution with a pipette, which should not give the slightest colouration on addition of a drop of colourless ammonium sulphide. As soon as this is the case, the battery is disconnected, the cone removed from the solution, thoroughly washed in distilled water, then in rectified alcohol, dried in a water-bath at  $100^\circ\text{C}$ ., and weighed. The weight of the cone having been previously noted, the increase found gives the weight of metallic nickel.

The whole process of separation and estimation need not occupy more than four hours, and of course several may be carried on side by side. I think it will be recognised that this is a decided advance on the older processes as regards time; and as to its accuracy, I have made many estimations, using solutions of carefully-prepared pure salts of cobalt and nickel mixed in various proportions, of which I give here a few of the results:—

Taken.		Found.		Per Cent. Found.	
Cobalt.	Nickel.	Cobalt.	Nickel.	Cobalt.	Nickel.

A A Blocks of Vulcanite.

Cone.

Spiral.

In conclusion, I have here shown a rough sketch of the apparatus employed, which may be more easily understood by those not specially conversant with electrolytic work.

# DISCUSSION.

Mr. STANFORD asked if the solution of the nickel salt was heated during electrolysis?

Mr. ROUGER said it had been his fortune to have a little to do with cobalt and nickel, and he was glad to hear that Mr. Hope had been so successful with his process—a process which he had something to do in bringing forward. He noticed one or two alterations Mr. Hope had made, which he could quite understand would be advantageous. One of these, especially, was the conversion of the salts into sulphates before the operation was commenced. In his time they were in the habit of working upon them as chlorides after the cobalt had been precipitated. By Mr. Hope's plan the process had been shortened a step.

Dr. MILNE said that some time ago Mr. Hope mentioned to him that he was making some experiments upon a volumetric method of determining cobalt, and he would like to know if he had had any reliable results in that way.

The CHAIRMAN said that if familiarity with the subject entitled a person to speak upon it, he was sure Mr. Hope must be considered as an authority upon the determination of cobalt and nickel. He could not of course give, off-hand, any opinion with regard to the details of the methods, but could only judge by the results. These results, considering the minute quantities operated upon, were satisfactory. He was glad to notice particularly that Mr. Hope had kept in view the necessity of testing the accuracy of the process by operating with a small quantity of cobalt and a large amount of nickel, and *vice versa*. This he regarded as an instance of the extreme accuracy which nowadays was obtained in technical laboratories. It was not so many years ago that professional chemists had to instruct technical chemists, but now he was very glad to be able to recognise that in many cases it was the reverse. The professional chemist could not possibly have a perfect knowledge of all processes used in manufacture, for the field was far too vast to admit of him gaining such a diversified knowledge, and it was to the technical chemist he must look for the extreme accuracy and correct methods for working out special processes. He was glad to say that in any instance where he had applied to works chemists for a description of the special methods employed for the determination of substances in connexion with manufacture, they at once responded to his request.

Mr. HOPE, in reply to Mr. Stanford, said the solution was kept at a temperature of 70° during the electrolysis. With reference to Dr. Milne's remark, when he promised to give a paper before the Society, he intended it to be on a volumetric process for the determination of cobalt, but not having the necessary time to work out the process, he thought it might be interesting to give the paper he had read to-night. He intended, however, to give the other paper on some future occasion.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### PATENTS.

*Improvements in Means or Apparatus for Separating Solid Matters from Liquid.* F. H. Danchel, Maidstone. Eng. Pat. 499, January 10, 1889. 8d.

The apparatus described in this specification is practically a continuous filter from which the solid matter is continuously removed. A cylinder (*a*) is formed from rings of thin

sheet metal held between the end plates *e* and *f* by means of tie bolts *g*<sup>1</sup>. In the interior is a cylinder *c* having formed upon its periphery the screw thread *c*<sup>1</sup>, and this can be rotated by the shaft *c*<sup>2</sup> by means of the gearing shown. The material to be filtered is forced into the cylinder through the pipe *c*<sup>2</sup> under pressure; the liquid escapes through the small interstices between adjacent plates, leaving the solid matter on the internal surface, from which it is scraped by the screw *c*<sup>1</sup> and forced from the machine through the pipes *d*, *d*<sup>1</sup>, which are closed by spring-loaded valves shown at *d*<sup>2</sup>. The operation of the whole is therefore continuous.

—C. C. H.

\* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Luck, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d. ....	1d.
Above 8d., and not exceeding 1s. 6d. ....	1d.
" 1s. 6d., " " " 2s. 4d. ....	1½d.
" 2s. 4d., " " " 3s. 4d. ....	2d.

*Improvements in Filters.* P. de Mol and A. Gerken, Brussels, Belgium. Eng. Pat. 676, January 14, 1889. *Sd.*

The filter consists of an outer casing A provided with a cover O fitted with an inlet pipe. In the interior of A three

separate vessels, I, H, G, are superposed. Each of these has a perforated bottom on which rests a disc or discs of cotton fibre; the bottom of G is covered with broken gas carbon, that of H with wood charcoal, and that of I with sponge. The perforated cover C is also sometimes covered with cotton waste. Filtration takes place through the whole depth of the apparatus, the unfiltered liquid entering at O, and leaving at R filtered.—C. C. H.

*Improved Filtering Apparatus.* E. Dueret, Paris, France. Eng. Pat. 1462, January 26, 1889. *Sd.*

T's is a perforated tube round which is wound the filtering material T', the whole being supported by the cap B o. The unfiltered liquid enters the chamber R, on the shelves of which some of the grosser matter is separated; passing by the pipe T it enters the vessel H, filters through the material T' and passes from the apparatus by the pipe T''. The stand pipe O allows any air which may be in the apparatus to escape. A jacket B M may also sometimes be used so as to raise the temperature of the liquid during filtration. Decolourising material is also sometimes used between the layers of the filtering material.—C. C. H.

(For drawing see top of next column.)

*Improvements in Apparatus for Automatically Softening, Cleansing, and Filtering Water Continuously or in Quantities as required.* J. Wright, London. Eng. Pat. 2695, February 15, 1889. *Sd.*

This invention has for its object the provision of such means as will ensure the operations of cleansing or softening and filtering the water being carried on jointly or separately without the expenditure of any power other than that supplied by the water itself; while the apparatus is so constructed as to cause the supply of water to it to automatically govern the starting and stopping of the operations as required; the quantity of water supplied to be cleansed,

softened, or filtered being capable of minute regulation." For the mode by which this is effected the two sheets of drawings attached to the specification must be consulted. There are three claims.—E. S.

*Improvements in Filters.* W. Mather, Salford. Eng. Pat. 3125, February 21, 1889. *Sd.*

This invention is applicable to that class of filters shown in the accompanying Figure, in which the material arrested in the filtering material is subsequently removed by a current of water passed through it in the opposite direction to that of filtration. A is the body of the filter, B the pipe conveying

the unfiltered water, C pipe conveying filtered water from the filter, E, E cleansing pipe. During the time the filter is in operation the pipe N transmits the pressure of the water to the flexible diaphragm I, and closes the end of wash-out pipe F. As soon, however, as the resistance in the filter increases the increased pressure due to such resistance lifts the weighted valve V, and thus allows the water in pipe K to escape into the suspended tank M, which then falls, closes valves B' and C', and opens valve E. Filtration then ceases, and the washing out of the accumulated impurities commences. To ensure the complete removal of the impurities, the tank M is kept down by a further rapid escape of water from pipe L, for as the pressure in K is diminished the diaphragm I falls and allows the dirty wash-water to be rapidly syphoned out of the filter. A reversal of the action occurs by the breaking of the syphon at G, and as the suspended plug S lightens the tank M by allowing the water to escape the counterpoise on V, reverses the valves and filtration again commences.—C. C. H.

*Improvements in Wooden Vessels for Carrying or Holding Corrosive Substances.* P. W. Turner, Glasgow. Eng. Pat. 5373, March 27, 1889. 4d.

The staves of barrels or other vessels are steeped in a mixture of solid paraffin and india-rubber or gutta-percha. —E. G. C.

*Improvements in the Construction of Filters and other Vessels.* G. Cheavin, Boston, Eng. Pat. 6222, April 11, 1889. 6d.

This invention relates to a method of securing plates or diaphragms forming the partitions and covers of filters and other vessels. The edges of the plate, instead of being of the same thickness all round, are made thickest at the end of one diameter and thinner at the end of the diameter at right angles to the first, the thickness varying between the two extremes. A notch is cut at one of the thinnest places. The seat upon which the plate rests consists of a ring fixed inside the vessel, and above the ring are two lugs diametrically opposite to each other. In putting the plate in place, the thinnest part opposite to the notch is first inserted between the ring and one of the lugs, the notch allowing the plate to pass the other lug and drop into its place, when a partial turn of the plate causes it to be wedged between the lugs and ring. The filtering medium employed is preferably "idiocharites," the top and bottom layers being coarser than the middle, and is placed between two discs of pure asbestos cloth.—E. S.

*Improvements in the Construction and Arrangement of Mechanical Retorts for the Treatment of Animal, Vegetable, and Mineral Matters.* R. Haig, Paisley. Eng. Pat. 6242, April 12, 1889. 6d.

This is a modification of a patent for mechanical retorts previously described by T. Rouet in Eng. Pat. 11,584 of 1886. The retort has a vertical shaft, to which are affixed plain rotary discs, one above the other, with stationary partitions between them. The material to be treated, whether animal, vegetable, or mineral, reaches the upper disc from a feeding apparatus, falls over the outer edge of that disc on to the partition, is there acted on by scrapers which sweep it towards the centre, where it falls through an opening to the next rotary disc, is there driven or swept again over the outer edge to reach the next division, and so on until delivered at the lowest point. On its passage through the retort it is exposed to any desired degree of heat. The improvements covered by the present patent consist in arrangements for: 1. Allowing the materials to reach the upper disc from an opening in the cover of the casing, made as near to the centre of the shaft as practicable. 2. Allowing the volatile products to escape through openings in the bottom of the retort instead of at the sides. There are two sheets of drawings.—B.

*Improvements in Apparatus for the Lateral Action or Induction of Fluids.* A. Morton and W. R. M. Thomson, Glasgow. Eng. Pat. 6932, April 23, 1889. 11d.

This is an improvement in the mechanical arrangement of ejector-condensers. The principal object of the improvements is to obtain greater ease and accuracy in the adjustment of the action of the ejector to various quantities and pressures of steam, to temperature and quantity of condensing water, and to height of lift.

The sketch shows an arrangement of several nozzles fitted to one case. For further details the specification and five sheets of drawings must be consulted.—B.

*Process and Apparatus for Cleaning the Filtering Bodies of Chamberland and other similar Filters.* O. André, Paris, France. Eng. Pat. 7050, April 27, 1889. 1s. 1d.

The filtering apparatus, composed of Chamberland tubes, clog rapidly, and consequently are not so convenient for use as they otherwise would be. In the form of filter described by the patentee means are provided to overcome this defect. The Chamberland tubes are arranged in the interior of a cylinder feeding into concentric pipes. Water is forced into the cylinder, passes through the tubes, and is led away by the collecting pipes. The accumulated impurities on the exterior of the tubes are removed by means of jets of water issuing from small tubes contiguous to the filtering tubes, and these are driven with considerable force against the filters. At the same time a current of water or steam may be forced through them from the interior to the exterior. After being fully cleansed filtration can be again resumed as before described.—C. C. H.

*Improvements in Method and Apparatus for Extracting the Liquid or Soluble Constituents from Disintegrated Vegetable Materials.* J. E. Seales, jun., Brooklyn, U.S.A. Eng. Pat. 19,002, November 26, 1889. 11d.

The apparatus described in this specification is intended for the extraction of the soluble constituents from disintegrated vegetable matters. F is a plunger fitting the tube A;

reciprocation of F is secured by the connecting rod and crank as shown. Opening from A through the contracted die L is an inclined strong vessel B with a tight cover C, and fed with water or other solvent by pipe D. The chopped vegetable matter, which is of course more or less fibrous,

is introduced through the hopper K. Reciprocation of plunger F drives the fibrous matter forward, and, aided by the friction of the sides of tube A, assisted by the resistance of the die L, a solid pellet is formed. Each motion of the plunger drives this against the liquid anvil in B, and whilst

the hydraulic buffer so produced compacts the mass the liquid displaced is driven through the interstices of the pellet and so removes the solid constituents. The liquid escapes through perforations shown in the walls of the tube and in the face of the plunger. Such a form of apparatus, the patentee states, is well adapted for the treatment of sugar canes, &c.—C. C. II.

A is the tower, B the shaft for access, C the removable side, D D struts for wedging the several parts of the side to

*Improvements in the Construction of Filters and Reagent-Feeders for the same.* J. W. Hyatt, Newark, New Jersey, U.S.A. Eng. Pat. 19,862, December 10, 1889. 11d.

THE invention consists chiefly in improved means for filtering fluids through a bed of granular materials by introducing the unfiltered fluid at the bottom of the filter bed. A series of inlet strainers is provided in the bottom of the filter bed, the water being forced through the bed to a series of outlet strainers, which may be located in another portion of the bed at its bottom, or in the upper portion a little below the surface. A special strainer is constructed by holding separate rods side by side, with slight interspaces, and preferably in the form of an annular bundle. Means also are provided for supplying a regulated volume of a coagulating substance to the unfiltered fluid in its passage to the filter. For details of the invention the specification and the seven sheets of drawings which accompany it must be consulted. There are five claims.—E. S.

the framework of the tower for the purpose of making tight joints when at work.

There are two sheets of drawings and four claims.—B.

*An Improved Boiling and Precipitating Tower.* G. A. Hanisch, Beuthen, Upper Silesia. Eng. Pat. 20,719, December 24, 1889. 8d.

THE invention refers to washing and boiling towers as used in many chemical processes, and which generally require a periodic cleaning out. The inventor proposes to construct them in such a manner as to ensure a considerable saving of time and materials in the cleaning process. For this purpose he makes one of the sides of the tower completely removable in parts, having previously built an upright shaft to adjoin the tower on that side, in order to allow access thereto without exposing the materials and gases to the outer atmosphere.

The accompanying diagram represents one of the arrangements in horizontal section.

*Improved Method of and Apparatus for Recovering Chemicals from Solutions, or when mixed with Substances which are Volatilizable or Destructible by Heat, especially adapted for Recovering Soda from Waste Liquors of Pulp Digesters.* M. B. Mason, S. D. Warren, and F. Warren, Boston, U.S.A. Eng. Pat. 20,908, December 31, 1889. 8d.

See under XIX., page 408.

## II.—FUEL, GAS, AND LIGHT.

*Note on a Treatise by Carl Otto on Improvements in Heating by Means of Gas at Constant Volume.* Schreier-Kestner. Bull. Soc. Ind. Mulhouse, 1889, 453—458.

ST. CLAIR DEVILLE, in 1868 (Compt. Rend. 67, 1089), advocated the heating of steam-boilers by fires supplied with compressed air; he considered that the heating surface

might then be lessened. Bessemer, however (Engineer, July 1869, 19), declared against the system of employing compressed air, holding that the compression to be effected would necessitate the employment of a machine which would in itself consume more work than corresponded to the actual gain subsequently effected, and so, on the whole, a loss would result. It is against this statement that Otto protests. In fact, on theoretical grounds, he is led to the conclusion that working under a pressure of 4 kilos. an economy of 23 per cent. is obtained, from which must be subtracted only the expense of compression, which, however, is compensated for by other advantages, such as more complete combustion, reduction in quantity of smoke, possibility of reducing size of apparatus. The author proceeds to point out that from calorimetric study of the combustion of oils it has been ascertained that steam-boilers can actually furnish 85 per cent. of their heat in steam. Otto thus obtains from the fuel more energy than it is by any means capable of giving. Otto arrives at a false result in taking count of the loss resulting from work absorbed by the chimney draught; instead of taking the temperature of the gases at the base of the chimney, he takes it at the fire.

—T. L. B.

#### PATENT.

*Improvements in Apparatus for the Combustion of Fuel.*  
F. Dinz, St. Jean des Vignes, France. Eng. Pat. 4830,  
March 19, 1889. 11d.

SEVERAL modifications are described and illustrated in the specification, but the essential features will be understood from the accompanying Figure. The arrows show the course

of the gases which come in intimate contact with the fuel. The latter is fed continuously into the uppermost central chamber from which it drops through the contracted orifice into the chamber next below it and so on, the ash ultimately falling into the ash box at the bottom of the series.—O. H.

result of the prospecting was that a thick stratum of rock salt was struck, and the salt-mining industry has in consequence been greatly developed.

This satisfactory outcome to his former labours, and the proof it affords of the value of the assistance which the Imperial Association is in a position to render, encourage the author to hope that his present report may be of some use.

As much as 12 years ago it was pointed out by different engineers that the Balakan naphtha differs considerably from that of Pennsylvania; thus, only about 37 per cent. of kerosene is obtainable from the Caucasian naphtha, while the Americans succeed in getting as much as 70 per cent. from theirs.

The main object of owners since the opening of the Baku industry has been to obtain from Apshehon naphtha a product resembling American kerosene as nearly as possible, and so prevent the latter from flooding the Russian markets. The Baku owners have been blamed for this by some authorities, it being thought that they ought to work out a special grade of oil. This objection, however, appears to the author unjust, competition necessitating the production of an oil undistinguishable by the consumer from American kerosene. The object at present aimed at in the Russian refineries is to obtain 37 per cent. (nearly) of kerosene and 55—50 per cent. of naphtha residuum, which is much used along the Volga for fuel. This last is so important as to be no longer a mere by-product, and hence naphtha has become a heating material as well as a lighting material. Up till 1878 this residuum or refuse was procurable for  $\frac{1}{2}$ —1 kop. per pud. Now it fetches 1 kop. per pud. The question is not yet settled as to whether this method of treatment is the most advantageous; for 12 per cent. of oil can be got by simple distillation from the residuum. These oils are heavier than petroleum (kerosene), but will burn in lamps. They are the so-called "solar oils" (heavy naphtha oils). The object of the writer is to introduce them into general consumption as a substitute for kerosene. The advantages of these oils are their exceptional safety, due to high flashing point. The author recommends their separation from the refuse, because he considers that to employ naphtha for lighting purposes is the most suitable use to which it can be put, and as for the employment of naphtha for heating purposes, that has already reached such a pitch of development that there is no danger of its ever being abandoned. This is due to the owners not knowing what use to make of the refuse. The specialist, however, desires to find out the most suitable use for a material.

It is not proposed in the present paper to deal with the products obtained by fractional distillation ("cracking") from heavy naphtha constituents. This process is too slow for commercial requirements. The product here to be considered is obtained by ordinary distillation, and is intermediate between kerosene and lubricating oils. It has been largely obtained in lubricating oil works, but has not hitherto been utilised. The reasons for this are—(a) the difficulty of obtaining a suitable lamp; (b) the difficulties and expense of refining. Its specific gravity is 0.870, and its flashing point from 100°—110° C. This is the so-called solar or intermediate oil.

As regards the lamp question, Kumberg obtained a prize for a suitable lamp in 1883, but his lamp has not been generally adopted. Since then several cheap lamps have been invented, and this has caused the author to re-direct his attention to the application of solar oil for lighting purposes. Last autumn Voïslar introduced a lamp said to burn the oil well, and another has since been invented by Bluman. This difficulty would doubtless be overcome if the oil came into more general use.

This is, however, not the only difficulty, for the trouble of purification renders the solar oil as yet more expensive than kerosene, and though it has the advantage of greater safety, this does not make up for the difference in price. The duty on solar oil is 30 kop., that on kerosene 40 kop.; but this difference is more than swallowed up by cost of refining. Mendeleeff states that the refining of solar oil is very difficult. The author used sulphuric acid (sp. gr. 1.835) and soda-lye (sp. gr. 1.23), employing 4 per cent. sulphuric acid and such an amount of caustic soda as to give 1—1 $\frac{1}{4}$

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*A Recommendation for the General Employment of Heavy Naphtha Oils for Lighting Purposes.* K. Lissenko.  
Bull. Soc. Impér. Poly. Russie, 1890, 24, 1—14.

THIS is a paper read before the Imperial Russian Technical Association. The writer commences by observing that some 15 years ago he presented a report on the subject of the rock-salt deposits situated between Bakkmoït and Slavausk, with the view of inducing the Ministry of Finance to make grants for the purpose of prospecting. The Imperial Association received his proposals with favour, and made a grant of 50,000 roubles for that object. The

per cent. in the oil, found that it could be easily purified. The precipitation must take place hot, and there is a greater loss but no special difficulty. The oil, though burning well in the Makaroff lamp, varied in colour. M. Ropps found the purification satisfactory, and a sample was sent through the Nobel Co. to Mr. Redwood in England. On another occasion the author tried to obtain oil of the same degree of purity, using sulphuric acid of sp. gr. 1.835, but did not succeed, and consequently concluded that he had not got to the bottom of the question. The ordinary criterion for kerosene, *i.e.*, to stir it with sulphuric acid of sp. gr. 1.50, when it should remain colourless or nearly so, does not hold for solar oil.

The oil submitted to the lamp committee by the Baskoff works, though it burned well in some lamps, was badly purified. To get a practical result the heavy oils will have to be refined to a corresponding equality with kerosene. At Baku it is held that the degree of purity obtained depends on the strength of the acid and the temperature employed. It is for this purpose of lowering the temperature to the desired point that such large coolers are used in that town. The author's experiments have confirmed those of other experimenters in Baku.

The result of a number of experiments with acids of different strengths, and also with Nordhansen sulphuric acid, and at various temperatures, went to show that the degree of purity attained depended on—

1. *Strength of Acid.*—Thus, when 4 per cent. of acid, sp. gr. 1.835 or 1.840, and cold treatment, were employed, the result was to give an oil of the standard sup. W. 21 mm. and 35 mm. respectively. Thus the small difference in specific gravity of 0.005 exercises an enormous influence on the result.

2. *Quantity of Acid.*—Oil refined with 3 per cent. and 4 per cent. of strong acid gave sup. W. 35 mm. and 30 mm. More extended experiments will doubtless show that there is a limit beyond which the influence of quantity will not be so apparent.

3. *Temperature.*—When treated with acid hot the resulting oil is heavier.

In Baku it is thought that the colour may be effected by the presence of nitric acid in the sulphuric acid. This is doubtless true, and hence the rule ought to be observed that only sulphuric acid free from oxides of nitrogen should be employed.

From these experiments it is clear that the cost of refining depends on the standard adopted. Ropps' purified oil is sold, it would seem, at 4 rh. 50 kop. per pud wholesale. The author considers that sup. W. 30 mm. ought to be a sufficient degree of purity, for which 4 per cent. of sulphuric acid of sp. gr. 1.84 may be used. The acid supplied at Baku will therefore require careful concentration, and he considers that the Baku acid works ought to give their attention to the manufacture of both fuming and anhydrous acid.

It must be remembered that the refining of the heavy oils requires three times as long as that of kerosene, besides the provision of a greater number of tanks and more elaborate heating apparatus, and consequently the difference of 10 kop. duty will be more than counterbalanced by the extra cost.

As there are so many grounds which make the general introduction of the heavy oils advisable, *e.g.*, their greater safety and the more economical exploitation of naphtha which would result, and as the cost of refining cannot, as far as can be seen at present, be much reduced, the author submits the following proposals:—

- (1.) That the Ministry of Finance be requested to make an alteration in the duty upon the various oils of such a kind that those hitherto rated at from 40—50 kop. should be in future rated at from 20—30 kop.
- (2.) That the latter should be dyed red, and that the employment of the dye should be understood as guaranteeing a sufficient degree of purity.

These proposals, if carried out, the author thinks, would lead to the general employment of the heavy oils for lighting purposes.

## PATENT.

*Improvements in and connected with Retorts for the Destructive Distillation of Shale or other Oil-yielding Minerals.* N. McFarlane Henderson, Linlithgow. Eng. Pat. 6726, April 20, 1889. *Sd.*

The minerals are first treated in a series of upper cast-iron retorts for the purpose of obtaining the crude oil, after which they are passed into a common intermediate chamber and thence into a series of lower fire-brick retorts, where they are acted on at a higher temperature by steam in order to drive off the carbonaceous and nitrogenous constituents remaining in the minerals as completely as is practically possible. The vapours evolved in the lower retorts are passed upwards and may proceed through the same outlet pipes as the oily vapours from the upper retorts, or through separate outlet pipes. On their way up from the lower retorts these highly heated vapours act on the minerals temporarily lodged in the common intermediate chamber, and distil off therefrom any oily vapour remaining or requiring for its evolution a greater heat than that acting in the upper retorts.—D. B.

## IV.—COLOURING MATTERS AND DYES.

*Production of Indigo.* Centralb. f. die Text. Ind. No. 3, 1890.

INDIGO in India is sown towards the end of February, and when the young plant has attained a height of from 6 to 8 in., it remains stationary till a rainy season, when it continues its growth. If this rain begins after the time of the hot winds, about the end of April, a good season may with certainty be counted upon, but if the rain only comes, as is usually the case, at about the middle of June, an average season will be the result, for which the plant will be ripe for cutting during the first week in June. After the plant has been cut to about 6 in. from the ground, it is brought in carts to the factory. There it is laid in the fermenting vats, which, when completely full, are covered over with boards, in order to prevent any of the plants being washed away when the water is run off. Water is then allowed to enter these vats, and the process of fermentation commences, causing the soluble colouring matter to separate out from the plant. The fermentation is caused by a micro-organism, and so long as there is the necessary nourishment for the growth of these bacteria, the production of the colouring matter will continue.

The fermentation lasts about 10 or 12 hours. After this time the nourishment for the bacteria begins to fail, and butyric acid fermentation, and afterwards putrid fermentation, set in, neither of which permit of the further formation of colouring matter. At the moment when the colour-forming fermentation is over, the yellowish-green liquid is run into another set of vats standing underneath the first series, and provided with a mechanical apparatus for heating the liquid, in order to bring it in contact with the atmosphere. The colouring matter, now insoluble in water, sinks to the bottom, forming a thick layer. If the water be now run off, crude indigo paste is obtained, which, by various methods of treatment, is freed from moisture and impurities. The colouring matter is pressed into sheets 1 metre square and 3 in. thick; then cut into cubes about 3 in. large, and lastly subjected, for several months, to an air-drying process, after which it is ready for packing and exporting.

The complaint which is often made as to the small yield of indigo from the plant is founded upon the comparatively short time allowed (10—12 hours) for the fermentation, during which the formation of any colouring matter was possible. The improved process discovered by Schrottky is based upon the lengthened period of fermentation, and the prevention or deferring of the butyric acid and putrid

fermentation. He found that those factories using water saturated with vegetable or animal matters obtained both less and an inferior quality of indigo than those which used pure water or water containing saltpetre. In the course of his experiments, therefore, Schrottky added nitrates to the water in the fermentation vats, in order to afford nourishment to the bacteria for a greater length of time, with the result that he obtained a yield of 12 to 15 per cent. more than he previously obtained. Further experiments were made to ascertain how long putrid fermentation might be postponed, and how long it was possible for the formation of colouring matter to take place. In this case the addition of carbolic acid was very successful, and the period of extraction was thereby so much lengthened that a much larger quantity of the colouring matter was obtained from the plant than was possible before. The increased production appears, however, to take place at the expense of quality. (See also this Journal, 1890, 224.)

*Azo- and Azoxytoluenes.* J. V. Janovsky. *Monatsh.* **10**, 585—601.

MONONITRO-PARAZO-TOLUENE is best prepared by treating azo-toluene with 5 parts of nitric acid of sp. gr. 1.43; the temperature should not rise above 30°, otherwise the dinitro-compound is also formed. It is readily soluble in ether, acetone, and light petroleum, and melts at 80°. When reduced with tin and hydrochloric acid it gives para-toluidine (m.p. 43°—44°) and meta-para-tolylenediamine, melting at 88°.

The most important reactions of the two tollylenediamines obtained from para-toluidine are given below; in both cases a neutral or slightly acid solution of the hydrochloride is employed:—

—	<i>o</i> -Tolylenediamine [CH <sub>3</sub> :NH <sub>2</sub> :NH <sub>2</sub> =1:2:4].	<i>β</i> -Tolylenediamine. [CH <sub>3</sub> :NH <sub>2</sub> :NH <sub>2</sub> =1:3:4].
Ferric chloride.	No change at first, after standing for a long time an orange colouration.	A wine-red colouration.
Potassium bichromate.	A yellowish-brown colouration.	A reddish-brown precipitate.
Potassium ferricyanide.	Olive-green crystalline plates.	A dark red colouration.
Bromine water.	A yellowish-white precipitate.	Brown flocks and a magenta-red solution.
Platinum chloride.	A yellowish-brown colouration.	A reddish-brown precipitate.
Gold chloride.	A brown precipitate.	A red solution with blue reflex and metallic mirror in the cold.
Potassium nitrite.	In very dilute solutions a golden-brown colouration, in concentrated a brown precipitate.	No colouration, but a salmon-coloured precipitate.
Solution of bleaching powder.	A reddish-brown colouration and then a light brownish-yellow precipitate.	A dark red colouration, then an olive-green precipitate.

Since the tollylenediamine (m.p. 88°) obtained (together with *p*-toluidine) from nitro-parazo-toluene gives all the reactions of *β*-tolylenediamine, the two compounds are identical, and the nitro-compound has the constitution—

The reactions given above can be employed, even in presence of other substances, for the detection and identification of tollylenediamines, compounds which so frequently result from the decomposition of azo-dyes.

Dinitro-azo-toluene (m.p. 114°) is obtained by treating parazo-toluene with nitric acid of sp. gr. 1.51. When reduced with an alcoholic solution of stannous chloride it yields an intensely yellow diamido-compound; this base dyes yellow, but the hydrochloride is colourless. When dinitro-azo-toluene is treated with tin and hydrochloric acid it gives meta-para-tolylenediamine (see above), so that its constitution is represented by the formula—

or

The two trinitro-azo-toluenes, melting at 138° and 189°, respectively, yield meta-para-tolylenediamine (m.p. 88°) and triamidotoluene on reduction with stannous chloride and fuming hydrochloric acid; the two bases can be separated by converting them into the sulphates and adding alcohol to the aqueous solution of the mixed salts, whereon the meta-para-tolylenediamine sulphate is precipitated.

The triamidotoluene obtained, crystallises in plates and becomes coloured on exposure to the air; the hydrochloride is crystalline and gives the following very characteristic reactions:—In dilute solutions ferric chloride produces no change at first, but after some time the solution turns brownish red. Potassium bichromate gives an olive-brown colouration and bleaching-powder solution, a rose-red colouration, and then a brown precipitate. Potassium nitrite, in very dilute solutions, produces a rose-red colouration, in concentrated solutions a dark brown precipitate. Sulphuric acid, mixed with a few drops of nitric acid, produces a steel-blue colouration analogous to that obtained with *α*-triamidobenzene. This triamidotoluene does not yield an eurdine, and has the constitution—

Since both the trinitro-azo-toluenes give meta-para-tolylenediamine and the same triamidotoluene they must be represented by the formula—

and

respectively.

Para-nitrotoluene gives two azoxytoluenes, an *α*-compound melting at 70° and a *β*-compound melting at 75°. The two substances are best prepared by gradually adding a quantity of zinc dust, rather less than that theoretically necessary to produce azotoluene, to a warm mixture of nitrotoluene and caustic soda (25°—30° B.). The reduced mass is then dissolved in hot glacial acetic acid, and the solution cooled to 20°—25°, whereon parazotoluene crystallises out. The mother-liquors deposit the *β*-azoxytoluene on standing, mixed with a small quantity of a compound melting at 109°, and on adding water to the filtrate the whole of the *α*-compound is precipitated. Both compounds can be easily purified by recrystallising from light petroleum. The relative quantity of the two products depends on the concentration of the soda and on the quantity of zinc dust used. These two azoxytoluenes have the same molecular weight, and both give paratoluidine on reduction with tin and hydrochloric acid. When treated with stannous chloride in warm alcoholic solution they both give yellow crystalline

compounds which are insoluble in acids, and are probably hydroxy-derivatives of the constitution—

and

respectively.

When  $\alpha$ -azoxytoluene is treated with nitric acid of sp. gr. 1.42 it gives a golden mononitro-compound which crystallises well from alcohol, melts at 51°, and on reduction gives an amido-azoxytoluene.  $\beta$ -azoxytoluene yields under the same conditions a crystalline nitro-compound melting at 82°. Both azoxytoluenes dissolve in fuming  $\text{HNO}_3$  (sp. gr. 1.51) yielding one and the same trinitro-compound which crystallises in prisms and melts at 196°.—F. S. K.

*Patent Blue and Acid Violet N.* E. Illich. Chem. Zeit. **13**, 1702—1704.

A NOTICE of patent blue has already appeared (this Journal, 1890, 53), and the present article deals with the technical uses of new shades of the original colour which appear in commerce as calcium salts of the sulphonated colouring base. Their advantages are stated to be:—1. Characteristic brilliant shade. 2. Very even dyeing. 3. Great fastness to alkalis and lime. 4. Considerable fastness to light. Whilst ordinary patent blue dyes a greenish blue, the shade “superfine and N” gives a pure blue, which shows to advantage by artificial light. The shade “I” closely approaches that of indigo carmine, and possesses many advantages over the ordinary substitute for indigo carmine, namely a mixture of acid violet and acid green. Acid violet N has a different chemical composition from ordinary acid violets, and possesses very similar qualities to patent blue. All these colouring matters dye wool in an acid bath with or without glauher salt or alum. On a chrome mordant they will dye in a neutral bath or in presence of acetic acid, which fits them for use in the same bath with alizarine dyes. The shades produced will stand a moderate amount of milling if care be taken to rinse well immediately afterwards, otherwise the colour will slowly bleed into the white. The dye baths should be preferably of wood, and the presence of copper should be avoided for the finer shades, especially on silk.

—G. H. B.

*Azo-Colouring Matters containing the Quinone Group.* F. Kehrman. Chem. Zeit. **14**, 93 and 146—147.

According to Witt's nomenclature *chromogens* are bodies generally belonging to the aromatic series which yield colouring matters having an affinity for animal and vegetable fibres on the introduction of *chromophors*, of which the nitro, azo, and quinone groups are examples. Although the function of chromophors is generally ascribed chiefly to the azo—

yet there appears reason to view certain colouring matters containing these groups as owing their characteristic properties to other possible chromophors which they may contain; thus Nietzki (Chem. Zeit. Rep. **13**, 343) ranks Weselsky's resorcinol colouring matters not as owing their essential qualities to their being “oxazine” or “phenoxazine” derivatives but to their containing the quinone imido group.

The author here remarks that the “oxazine” group in such a body as “phenoxazine” (oxydiphenylamine)  $\text{C}_6\text{H}_5 \cdot \text{ON} \cdot \text{H} \cdot \text{C}_6\text{H}_5$  and the “thiazine” group in thiodiphenylamine  $\text{C}_6\text{H}_5 \cdot \text{SN} \cdot \text{H} \cdot \text{C}_6\text{H}_5$  allow of the comparison of these bodies with hydrophenazine (diphenylene hydrazine)  $\text{C}_6\text{H}_5 \cdot \text{N}_2 \cdot \text{H}_2 \cdot \text{C}_6\text{H}_5$  better than with phenazine (azophenylene)

$\text{C}_6\text{H}_3\text{N}_3\text{C}_6\text{H}_4$ , the former corresponding with quinol  $\text{C}_6\text{H}_4(\text{OH})_2$ , the latter to quinone  $\text{C}_6\text{H}_4\text{O}_2$ . It is therefore conceivable that phenazine may be viewed as a chromogen, a position not held by “phenoxazine” and “phenthiazine” (thiodiphenylamine). Although attention has been paid to the effect of the introduction of various chromophors into artificial colouring matters, yet hitherto none has been prepared which can be viewed as a combination of an azo compound with a quinone, on account of the difficulty of synthesising any such body. The author has attempted to attain this object by starting with hydroquinone, but has been unable to diazotise it on account of its suffering oxidation in the process.

In conjunction with Tiesler (J. prakt. Chem. **40**, 480) the author has found that the hydrogen atom attached directly to the nucleus in chloro-*p*-dihydroxyquinone  $\text{C}_6\text{H}(\text{OH})_2\text{ClO}_2$  is easily replaceable by halogens and ( $\text{NO}_2$ ). Arguing from this he expected the ready formation from it of mixed hydroxyazoquinones, and verified this deduction not only in the case of monochlorodihydroxyquinone, but also in that of the paradihydroxyquinone of Nietzki and Schmidt and its substitution products, chlorodihydroxyquinone and nitrodihydroxyquinone, as well as in that of the dihydroxytoluquinone of Zincke and Hagen and hydroxynaphthoquinone. The reaction does not occur, however, in those bodies in which the (OH) group is not in the same nucleus as the quinone group. Hydroxyanthraquinones apparently yield no azo-colouring matters.

The class of substances thus produced are generally yellow-red to brown-red bodies soluble in the cold in alkalis and forming crystallisable salts.

An example of the mode of formation of one will serve as a type:  $\text{C}_{10}\text{H}_7(\text{OH})\text{O}_2 \cdot \text{N}_2 \cdot \text{C}_6\text{H}_5$ , *hydroxynaphthoquinone azobenzene*, is formed by dissolving the finely powdered sodium salt of hydroxynaphthoquinone (1 mol.) in 40 to 50 times its weight of boiling water, and stirring in a solution of diazobenzene chloride (1 mol.) to which has been added sodium acetate to remove free hydrochloric acid. The separation of the new substance begins at once and is quantitatively complete in half an hour. It is yellowish-red in colour, insoluble in water, slightly soluble in boiling alcohol and benzene, fairly soluble in boiling glacial acetic acid, from which it crystallises in bright red felted needles melting at 220—225° C.; dried at 120° C. it gave on analysis the following figures C 68.60, H 3.93, N 10.73 parts per cent. respectively instead of the theoretical values, C 69.06, H 3.59, N 10.07. The shade of colour similar to but intenser than that of hydroxybenzene azobenzene and the ready solubility of the substance in dilute alkalis forbid the supposition that it should be regarded as a “hydrazide” (hydrazone)  $\text{C}_{10}\text{H}_7\text{O}_3 \cdot \text{N} \cdot \text{NH}(\text{C}_6\text{H}_5)$ . The presence of the quinone group appears therefore to have an inconsiderable influence on  $\beta$ -naphthol azo-colouring matters; the same has recently been shown to be true of the ketone group by Witt (Ber. **21**, 321). Tetrazodiphenyl from benzidine (paradiamidodiphenyl) gives when treated with excess of hydroxynaphthoquinone a dark brown-red colouring matter which is doubtless tetrazodiphenyldihydroxynaphthoquinone  $\text{C}_{10}\text{H}_7(\text{OH})\text{O}_2 \cdot \text{N}_4 \cdot (\text{C}_6\text{H}_5)_2\text{N}_2\text{O}_2(\text{OH})\text{C}_{10}\text{H}_7$ . By not using an excess of hydroxynaphthoquinone but supplying the place of a portion of it with some amine or phenol mixed tetrazo-compounds can be obtained.—B. B.

#### PATENTS.

*A Process for the Production of Azo-Colours from the Para-diamines of Stilbene and Fluorene.* C. A. Martius, Berlin, Germany, May 31, 1886. Amended, November 30, 1889. 6d.

The revised claim is as follows:—“The production of azo-colours which dye cotton direct from a soap-bath, by combining one molecule of the tetrazo-compounds of stilbene or fluorene . . . . . with two identical or different molecules of an amine or phenol, such as  $\alpha$ -naphthylamine,  $\beta$ -naphthylamine, dimethylamine, diethylaniline, diphenylamine, phenyl-naphthylamine, tolyl-naphthylamine, carboic acid, cresote, resorcin,  $\alpha$ -naphthol or  $\beta$ -naphthol.

or their sulphonic or carbonic or sulphocarbonic acids." For further details the amended specification itself must be consulted. The original specification has been abstracted in this Journal, 1887, 437.—O. H.

*Processes for the Production of Azo-Colours that Dye Cotton direct from a Soap-Bath.* C. D. Abel, London. From the "Actiengesellschaft für Anilin-Fabrication," Berlin, Germany. Eng. Pat. 6687, May 6, 1887. Amended, November 30, 1889. 8d.

THE processes have already been described in this Journal, 1888, 43. The emendations, which in no way affect the claims, are chiefly literal, except in the example B (1) (see abstract already cited), viz., the production of a mixed azo-colour from benzidine,  $\beta$ -naphthylamine disulphonic acid R, and  $\beta$ -naphthylamine. It was stated in the original specification that "instead of using naphthylamine in a hydrochloric aqueous solution it can also be used as a free base in an alkaline solution." The word *alcoholic* is now substituted for *alkaline*.—O. H.

*Improvements in the Manufacture of Colouring Matters.* O. Murray, London. From G. C. Zimmer, Mannheim, Germany. Eng. Pat. 13,798, September 24, 1888. 6d.

"This specification has been reprinted in consequence of an amendment made by order of the Comptroller prior to the sealing of the patent." The emendations are not, however, shown. (Compare this Journal, 1889, 610.)

—O. H.

*Improvements in the Manufacture of Red Colouring Matters suitable for Dyeing and Printing.* I. Levinstein, Manchester. Eng. Pat. 3048, February 20, 1889. 6d.

THIS specification describes the preparation of a base by heating *m*-xylydine with sulphur and combining its diazo-compound with phenols or their sulphonic acids, or using the sulphonic acid of the base for diazotisation and combinations. (See also this Journal, 1889, 980.)—T. A. L.

*Improvements in the Manufacture of Picric Acid.* E. Eisenmann, London, and A. Arche, Vienna, Austria. Eng. Pat. 4539, March 15, 1889. 4d.

CARBOIC acid is converted into phenoltrisulphonic acid by the aid of sulphuric acid, and this is transformed into picric acid by means of sodium nitrate. The temperature need not exceed 100°, whilst the yield of pure picric acid is equal to about 155 per cent.—D. B.

*A Process for the Production of Orymethoxybenzoic Acids.* J. Y. Johnson, London. From Dr. F. von Heyden Nachfolger, Radcben, Germany. Eng. Pat. 5785, April 4, 1889. 6d.

THIS is an application of Kolbe's salicylic acid synthesis to guaiacol, cresol, and eugenol, in order to obtain the carboxylic acids of these compounds. The process consists in either passing carbonic acid over an alkaline salt of guaiacol heated to a temperature above 100° C. or in performing this operation under pressure. The reactions can be respectively represented as follows:—

When the reaction is complete the product is dissolved in water and a mineral acid added when the guaiacol carboxylic acid crystallises out with 2 molecules of water. When anhydrous it melts at 148°—150° C. In an aqueous solution it gives a blue colour with ferric chloride and is decomposed on heating into guaiacol and carbonic acid. By substituting

cresol and eugenol for guaiacol in the above process, the following compounds are respectively obtained:—*Cresol carboxylic acid*—

and *Eugeninic acid*—

The acids are to be employed in the manufacture of azo-dye-stuffs.—T. A. L.

*Production of an Imide Compound of Fluorescein Chloride and of Colouring Matters therefrom.* O. Murray, London. From "The Farbwerke vormals Meister, Lucius and Brünig," Höchst, Germany. Eng. Pat. 6134, April 15, 1889. 6d.

WHEN fluorescein chloride is heated with concentrated aqueous ammonia to 200° C. for 6—8 hours, water is given off and an imide is formed having the composition  $\text{C}_{20}\text{H}_{11}\text{Cl}_2\text{NO}_2$ . The same compound is obtained by heating fluorescein chloride with sal-ammoniac in presence of lime and zinc chloride, but in this case coloured basic products are also formed, part of the chlorine being replaced by amidogen. The imido-compound of fluorescein chloride is colourless and melts at 235° C. It is insoluble in water and aqueous acids or alkalis, but dissolves easily in warm alcohol, benzene, or chloroform. It is not acted on by concentrated hydrochloric and sulphuric acids nor by boiling with zinc powder in an alkaline alcoholic solution. When fused with fatty and aromatic bases or their hydrochlorides in presence of zinc chloride to 270°, it forms red to bluish-violet colouring matters soluble in alcohol which on sulphonation can be rendered soluble in water.—T. A. L.

*Improved Apparatus for the Production of Colouring Matters.* J. E. Bedford, Leeds. Eng. Pat. 6778, April 23, 1889. 6d.

AN apparatus devised for the purpose of subjecting the lichens known as orchella weed to the prolonged action of ammonia and atmospheric air in presence of water in order to produce colouring matters. The process is considerably accelerated by using oxygen in place of air or together with it. In order to expose as large a surface as possible to the action of the gases, a vertical vessel is employed containing a number of trays, the edges of which are turned downwards so that they retain a certain portion of the gases pumped in at the bottom of the vessel. Scrapers fixed to a vertical shaft prevent the deposit of colouring matter on the upper surface of the trays and also serve to agitate the liquid. The deposition of the colouring matter is further aided by the application of heat. A vertical section of the vat accompanies the specification.—T. A. L.

*The Manufacture of Dyestuffs from Oxyethers of Alpha-Naphthylamine and their Sulpho Acids.* S. Pitt, Sutton, Surrey. From L. Casella and Co., Frankfort-on-the-Maine, Germany. Eng. Pat. 7067, April 27, 1889. 6d.

THE oxyethers of  $\alpha$ -naphthylamine are obtained from the  $\alpha$ -nitronaphthols by first converting them into the ethers and subsequently reducing the compounds, or the naphthol ethers may be nitrated and then reduced. According to the latter method the process is performed as follows:—17·2 kilos. of naphthol ethyl ether are added to 30 kilos. of nitric acid of 40° B. at a temperature below 40° C. The nitro-compound is washed with water and reduced with 20 kilos. of iron in presence of hydrochloric or acetic acid. The reduction product may be purified by precipitation as hydrochloride or sulphate. The methyl, amyl or benzyl ethers may be substituted for the ethyl ether above mentioned. The bases are scarcely soluble in water, but dissolve easily in alcohol and ether, giving solutions having a violet fluorescence. To convert the bases into sulphonic acids they may be directly sulphonated or the nitro-naphthol ethers can be sulphonated and reduced. A better method, however, is to convert the naphthol sulphonic acid into the

ether and nitrate, and reduce it, or the naphthol ethers may be sulphonated, nitrated, and reduced. According to the former method 24.6 kilos. of sodium naphthol sulphonate are dissolved with 4 kilos. of sodium hydrate in 200 litres of 50 per cent. alcohol. 11 kilos. of ethyl bromide are added and the mixture is heated for several hours to 60°–80° C. The naphthol ethyl ether sulphonate crystallises out on cooling in large silvery crystals, and after drying is added to cold nitric acid of 40° B. in which it dissolves with a dark yellow colour. The solution is poured into water and the nitro-sulpho-naphthol ethyl ether precipitated by the addition of salt. This on reduction yields ethoxy- $\alpha$ -naphthylamine sulphonic acid in the form of colourless needles sparingly soluble in water. These products are all capable of combining with diazo-compounds to form dyestuffs, and as they themselves contain a free amido group the compounds can be rediazotised and combined with phenols and amines. The two following examples describe the preparation of the dyestuffs. (1.) 30 kilos. of naphthylamine disulphonic acid are diazotised and combined with a solution of 21 kilos. of methoxy- $\alpha$ -naphthylamine hydrochloride, when the dyestuff forms immediately and precipitates. (2.) 34 kilos. of benzidine disulphonic acid are diazotised and combined with amido naphthol ether. The product is rediazotised and forms a sparingly soluble tetrazo-compound which is combined with 50 kilos. of  $\alpha$ -naphthol- $\alpha$ -sulphonic acid. The colouring matter dyes wool, silk, and cotton a dark blue shade. The colouring matters derived from diazo-compounds and the naphthol ether sulphonates give red to violet shades. On diazotisation they form yellow to brown tetrazo-compounds which when combined with phenols or amines produce dyestuffs of dark greenish blue shades.

—T. A. L.

*Manufacture of Green and Violet Colouring Matters.* C. D. Abel, London. From "The Actiengesellschaft für Anilinfabrication," Berlin, Germany. Eng. Pat. 7550, May 6, 1889. 6d.

A PROCESS for condensing methyl or ethylbenzylsulphonic acid with aromatic aldehydes and oxidising the leucosulphonic acids thus formed, so as to obtain green and violet dyestuffs. 50 kilos. of methyl or ethylbenzylaniline are gradually added to 120 kilos. of fuming sulphuric acid at 40°–50° C., and the melt is heated to 80° C. until a test dissolves in dilute caustic alkali. 100 kilos. of water are then added, and the sulphonic acid is precipitated by adding 100 kilos. of caustic soda of 40° B., after which it is filter-pressed and dried. 80 kilos. of ethylbenzylsulphonic acid, 34 kilos. of benzaldehyde, and 30 litres of water are heated, under an inverted condenser, at 110° C. for 78 hours, with constant stirring, 1,000 litres of water are then added, the solution neutralised with caustic soda, and the leucosulphonic acid precipitated at 30° C. with hydrochloric acid. In order to oxidise it, 100 kilos. of the dry acid and 31 kilos. of caustic soda of 40° B. in 400 litres of water are mixed with 120 kilos. of peroxide of lead (containing 34 per cent. of  $PbO_2$ ) suspended in 1,500 litres of water. The mixture is kept at 20° C., and the oxidation effected by adding, as quickly as possible, 45 kilos. of sulphuric acid of 66° B. in 300 litres of water. After stirring for some time, 30 kilos. of soda in 200 litres of water are added, the lead removed by filtration, and the colouring matter precipitated by the addition of salt. It is again dissolved in 1,000 litres of cold water, filtered and precipitated with brine, after which it is filter-pressed and dried. The colouring matter is readily soluble in water, less so in alcohol. Dilute mineral acids precipitate the free acid, whilst concentrated acids turn the green solution of the colouring matter yellow. Free alkalis destroy the colour of the solution.—T. A. L.

*Improvements in the Manufacture of Blue Colouring Matter for Laundry, Bleaching, and other Purposes.* M. Williams, Bootle, and J. Aseough, Handsworth. Eng. Pat. 9442, June 7, 1889. 4d.

FARINA, sago or rice flour, starch, china clay, or other suitable substances are to be mixed with a soluble blue,

and subsequently treated with borax, boracic acid, or other boron compound for use as "antiseptic blue" for household purposes.—T. A. L.

*Process for the Production of Mixed Azo-Colours.* P. Jensen, London. From "The Actiengesellschaft für Anilinfabrication," Berlin, Germany. Eng. Pat. 15,296, December 12, 1885. Amended December 27, 1889. 6d.

THIS amended specification more clearly describes the processes. For the ambiguous words "*acting afterwards upon*," which repeatedly occur both in text and claim, are substituted the more definite "*combining the products obtained with*." Also in Example 1 (see abstract of original specification, this Journal, 1886, 595) a correction is made in the weight of the sodium acetate employed in the preparation of the colouring matter from benzidine, naphthionic acid and  $\beta$ -naphthylamine sulphonic acid.—O. H.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

### PATENT.

*A Process and Apparatus for freeing Wool from Grease.* L. Pinagel, Aachen, Germany. Eng. Pat. 20,936, December 31, 1889. 8d.

IN the valuation of wool the quantity of moisture and wool-grease it contains must be considered, and the apparatus patented is for estimating the latter. A vessel containing ether, light petroleum or carbon disulphide, is heated by a water-bath and the vapour of the solvent passed into the sample to be extracted and thence to a vertical condenser, whence it drops back on to the wool and is returned to the vessel at intervals. A gauge glass fixed to the portion of the apparatus containing the wool serves to show when the extraction is complete by the solvent ceasing to be coloured yellow.—B. B.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*The Composite Indigo-Indophenol Vat.* G. Galland. Bull. Ind. Soc. Rouen, 1889, 330–331.

THE substance of this report has already appeared in this Journal, 1889, 618; also 1889, 189, 282, and 539.—E. B.

*Firing of St. Denis Red.* H. Koechlin. Bull. Soc. Ind. Mulhouse, September 1889. Appendix, 38–39.

THE mordant used consists of—

500 cc. of magnesium acetate of 30° B.,  
500 cc. of water,  
250 cc. of aluminium acetate,  
or of—  
150 grms. of magnesium sulphate,  
50 grms. of alum,  
1 litre of water.

(The alumina may be replaced by chrome alum, which is also a good mordant for these colouring matters.)

The mordant is fixed by passing the material prepared with it through an alkaline solution of a metal, the following solution having the preference:—

1,000 cc. of water,  
50 grms. of zinc sulphate,  
100 grms. of caustic soda of 38° B.

Dyeing is performed at 80° with 2 to 3 grms. of St. Denis Red—

2,500 cc. of water,  
5 grms. of lime,  
500 grms. of salt.

These quantities suffice for 1 metre of calico. For subsequent use the bath needs replenishing only with colouring matter and lime. Alum added to the dye-bath in small quantity is very beneficial. The above mordant is suitable for fixing Ponceaux, Bordeaux, and other similar colours, such as the new blue of Meister, Lucius, and Brünig.—T. L. B.

*Note on the Bleaching of Cotton by Hydrogen Dioxide.*  
H. Koechlin. Bull. Ind. Soc. Rouen, 1889, 332.

*An Improvement in Bleaching.* H. Koechlin. Bull. Soc. Ind. Mulhouse, September, 1889. Appendix, 39—40.

A NEW factor is introduced, viz., magnesia, as well as the use of hydrogen peroxide in cotton bleaching. The author treats five pieces of calico of 100 metres each for six hours at the boil with—

100 litres of water,  
10 kilos. of fused caustic soda,  
30 kilos. of soap,  
5 kilos. of calcined magnesia, and  
50 litres of hydrogen peroxide.

The method is too costly for general use, but is exceedingly useful, when pressed for time. The bleaching is much better than that obtained by the ordinary processes, and the fibre suffers less.

The operation may be performed in Mather and Platt's apparatus. For 220 pieces of 100 metres each, or 2,200 kilos. of material are necessary—

3,000 litres of water,  
400 litres of hydrogen peroxide (12 vol. strength),  
20 kilos. of calcined magnesia, and  
50 kilos. of soap.

After six hours' boiling, wash, acid, wash and dry. It is advisable to give the goods a preliminary souring in sulphuric acid of 2°, and then to allow them to lie in pile 12 hours, and wash before bleaching.

Tussah silk is bleached a much better white when magnesia is added to the hydrogen peroxide, than when ammonia is added.

Better results are obtained in bleaching calico by Mather and Platt's method, when magnesia is added to the caustic soda. In every case it is necessary to exclude air; observing this precaution cotton may even be treated in a Mather and Platt's keir with a relatively strong solution of bleaching powder.—T. L. B.

*On a New Chromium Mordant for Cotton.* E. Kur.  
Chem. Zeit. 13, 1669.

THE new mordant is chromium bisulphite, which may be obtained in solution by passing sulphurous acid gas to excess into water holding in suspension chromium hydrate obtained by precipitating a cold solution of chrome alum with ammonia. About 24 hours' digestion are required for complete solution of the hydrate. On the large scale the mordant is best prepared by dissolving chrome alum in twice its weight of boiling water, and, after cooling to 15° C., adding a concentrated solution of sodium bisulphite until the colour of the mixture changes from bluish-green to yellowish-green, any excess of sodium bisulphite being advantageous. The cotton material is padded in this liquid, and then allowed to drain for two hours, after which it may be either dried or steamed, the latter being preferable, as the dried material is not easily wetted again. The mordanted goods may be rinsed to remove any loose particles of chromium hydrate without risk of removing the actual mordant. The material can be oiled before mordanting, an advantage possessed by this process over Koechlin's alkaline method of chroming, which removes the oil. In calico printing the mordant may be discharged

with oxalic or tartaric acid, or the chromium bisulphite mordant may be thickened with starch and printed on, with subsequent steaming for fixation. Bisulphite compounds of the alizarin colours can be mixed with the chromium bisulphite solution, printed at once on the calico, and fixed by steaming, as previously proposed by Mullerns. Alumina, iron, and other metallic oxides may be applied as mordants to vegetable tissues, in a similar way.—G. H. B.

*Steam Aniline Black.* A. Kortész. Chem. Zeit. 14, 179—180.

AN essential condition for the production of the "ungreenable steam aniline black" is the freedom of the colour-mixture from excess of mineral acid. Higher oxidation of the ordinary black is not, as is generally supposed, alone sufficient. This is shown by the following considerations:—A fent padded in a colour-mixture, intended for developing aniline black by ageing, dried, and steamed, is coloured a "greenable" black; an addition to such a mixture, keeping constant the proportion of aniline, &c. present, of a certain amount of ammonium ferrocyanide renders the black obtained ungreenable; if now, to the latter mixture, excess of hydrochloric acid be added, the black produced will be again greenable. The experiment can be varied in the following way:—A fent is padded with an ordinary steam-black mixture, dried, spotted here and there with dilute hydrochloric acid, suitably thickened, steamed, and chromed; the spots appear of a bronzy-black hue on the black ground, but by treatment with sodium bisulphite they are turned green, the rest of the cloth remaining black. Whether the ferrocyanide in the steam-colour neutralises the mineral acid in becoming itself converted into aniline ferrocyanide, or whether its chief use is in forming a basis of Prussian blue, is more of theoretical interest.

Regarding the behaviour under steaming of the ordinary black mixture intended for ageing, experimenting with slop-padded fents, it was found that the black developed regularly and properly by hanging in an ageing room, yielding a colour which greened considerably under the influence of sodium bisulphite, but which did not affect the strength of the fibre, whilst, when developed by a passage through a Mather and Platt's "steam aniline-ager," the black did not green so badly, but the fibre was slightly affected, and by steaming without pressure for half an hour the fibre was completely tendered, and the black, when tested, still showed, though in less degree, signs of greening.

When the various ingredients in the colour-mixture were increased in quantity by 10 per cent., the tendering action on the cotton was increased, the blacks were more intense, but were still greenable. With a colour-mixture weaker in the same proportion, the greening was more apparent, but the fibre naturally was less injured. The standard mixture, with which these experiments were made, consisted of 2,600 grms. of aniline, 2,900 grms. of hydrochloric acid of 19½° B., 1,500 grms. of sodium chlorate, further—300 grms. of aniline, 60 cc. of vanadium solution, and sufficient water to make 31.5 litres. It was next ascertained how basic such a colour-mixture could be made without the development of the black being prevented. The limit of basicity was found to be reached with 2,500 grms. of hydrochloric acid instead of 2,900 grms. in the preceding mixture. The blacks produced with the basic mixture were greenable, but were formed with less injury to the fibre. Acetic acid added to a basic mixture appeared to be without action, the blacks developing exactly the same as though it had been absent.

Very similar results were obtained when the sodium chlorate in the standard mixture was replaced by other chlorates. Ammonium chlorate, recommended by Rosenstiehl, and aniline chlorate, proposed by Paraf, as yielding ungreenable blacks, were found no better for this purpose than sodium chlorate. Chromium and aluminium chlorates yielded less greenable blacks, but the fibre was more injured. Of the ferrocyanides the best results were obtained with the ammonium salt. Almost as good results were obtained with pure aniline ferrocyanide, but the crude compound, mixed as it is with potassium chloride, gives inferior results.

The ammonium ferrocyanide used was prepared by mixing the solutions of 18 kilos. of potassium ferrocyanide in 32 litres of water and 9 kilos. of ammonium sulphate in 13 litres of water, and allowing the potassium sulphate formed to crystallise out; 1 litre of this solution contains an amount of ferrocyanide equivalent to 340 grms. of the potassium salt. The standard steam-colour was made by replacing the vanadium salt in the recipe given for the aged-black by 2,590 grms. of potassium ferrocyanide or a corresponding amount of another ferrocyanide. This proportion of ferrocyanide must not be exceeded or else a bronzy-black is produced. In certain cases, for example, with superior cloth, it is preferable to slightly reduce the amount; thus, for goods which are to be steamed 2,000 grms. may be used, and for goods which are merely passed through an aniline-ager 1,800 grms. of potassium ferrocyanide will suffice instead of the quantity mentioned above. With less than these quantities tendering of the fibre was invariably found to take place.

The quantity of hydrochloric acid in the steam-colour can be reduced from 2,900 grms. to 2,500 grms., the amount of ferrocyanide being at the same time reduced in the same proportion. Equivalent quantities of ferricyanides, used instead of ferrocyanides, gave fuller shades, but the same results were obtained by slightly increasing the amounts of chlorates in the ordinary mixtures.

With ammonium ferrocyanide chroming of the steamed black is unnecessary, this operation being best replaced, in this case, by a rinsing in slightly acidulated water.

It must be pointed out that all the experiments here described were made by sloop-padding the cloth, so that for machine-work slight modifications in the proportions of the several ingredients would have to be made.

Some further experiments were made to ascertain the effects of the admixture of the acetates of certain metals with the ordinary aged-colour. The acetates of copper, iron, and chromium, when not present in excess, were found to have a beneficial action: the black developed more quickly, was deeper in shade and less greenable, but the fibre was injured by steaming. Copper acetate gave the best result. When a metallic acetate is added to a solution of aniline hydrochloride, it may be assumed that aniline acetate and a metallic chloride are formed, and it is found that when excess of metallic acetate is added to a colour-mixture, so that theoretically no hydrochloride is left, the development of the black takes place imperfectly, if at all.—E. B.

#### *Indamine Blue.* E. Ullrich. Chem. Zeit. **14**, 375—376.

This dyestuff, which is sold in the form of a paste, is the hydrochloride of a base of the induline series. Like other members of the same group, it is used for dyeing shades of blue, resembling indigo, on the various fibres. On wool it may be applied either in a neutral or slightly acid bath. It gives very even shades, but the colours possess the disadvantage of rubbing off. Cotton can be dyed in several ways. The brightest shades are obtained by mordanting with tannic acid, fixing with a salt of antimony, dyeing in a bath of the dyestuff, and then immediately, without rinsing, working the dyed material in a bath containing either 15 per cent. of the weight of the cotton of potassium bichromate or 2.5 per cent. of potassium bichromate with 0.8 per cent. of sulphuric acid, at a temperature of 50°—60° for 10 minutes. For dyeing a full shade, the cotton must be mordanted with at least 10 per cent. of its weight of tannic acid.

Another plan consists in applying the dyestuff on unmordanted cotton in a bath containing sodium acetate; 10—20 per cent. of the dyestuff used remains in the dye-bath. The cotton is, without rinsing, chromed with 15 per cent. of its weight of bichromate of potash, or, better still, with a mixture of 2 per cent. of this salt and 3.5 per cent. of copper sulphate, these being the proportions required to form copper chromate. As a certain amount of metallic oxide fixes on the cotton, in combination with the insoluble colour formed, the goods can be topped with logwood, &c. without further mordanting. It is, however, preferable, when such colouring matters are to be subsequently

applied, to increase the quantity of copper chromate in the oxidising bath to, say, 6 per cent. of potassium bichromate and 10 per cent. of copper sulphate, and to boil the goods in such a solution for an hour.

For calico printing, the paste only requires mixing with a thickening containing a little acetic acid, and steaming, in order to give fairly fast colours, whose fastness is further increased by chroming. The acetate and tartrate of the colour-base give the best results. The chief reactions of an aqueous solution of Indamine blue R. are as follow: sodium hydrate precipitates the base of a dark red-violet colour; tannic acid completely precipitates; concentrated sulphuric acid dissolves the dyestuff with a blue colour; stannous chloride produces a slight precipitate; zinc dust and ammonia decolourise.—E. B.

#### PATENTS.

*Improvements in Scouring or Cleansing and Bleaching Textile Fabrics, Warps, and Yarns formed of Cotton or other Vegetable Fibres, and in Apparatus to be used for the Purpose.* E. Bentz, Manchester, and C. and A. Edmeston and E. Grether, Salford. Eng. Pat. 5590, April 2, 1889. 8d.

THE improvements relate to a method of scouring, preferably with a solution of caustic soda, fabrics, &c. composed of cotton or other vegetable fibres. A steam-tight vessel is fitted with a system of rollers and steam-pipes, and its exit and entrance are closed against the admission of air or escape of steam by a seal of the caustic liquor. The material to be scoured passes continuously through the machine, being alternately subjected to the action of the boiling caustic solution and steamed. For mechanical details, the drawings illustrating the specification must be consulted.—E. B.

*Improvements in the Preparation of Bleaching Agents.* D. G. FitzGerald, Brixton. Eng. Pat. 5995, April 8, 1889. 6d.

See under XI., page 397.

*Improvements in Method and Apparatus for Extracting the Liquid or Soluble Constituents from Disintegrated Vegetable Materials.* J. E. Searles, jun., Brooklyn, U.S.A. Eng. Pat. 19,002, November 26, 1889. 11d.

See under I., page 379.

*Improvements in and relating to Printing in Colours, and Apparatus therefor.* P. A. Godchaux, Paris, France. Eng. Pat. 522, January 11, 1890. 1s. 1d.

THIS patent relates to the printing in colours of paper. The printing-machine by which this is effected consists of a number of rotary printing appliances, adjustably mounted in a common frame, each appliance being provided with pressure rolls and inking devices. Arrangements are introduced for drying the ink printed upon the paper by one appliance before it passes to the next appliance. For details of the arrangements and mechanism, reference must be made to the drawings accompanying the original specification.—E. B.

*Apparatus for use in Treating and Dyeing Cotton Slivers, Roving, or Cops, and other Textile Materials.* R. Haddan, London. From J. Bertrand-Leplat, Turcoing, France. Eng. Pat. 703, January 14, 1890. 8d.

TEXTILE materials more or less advanced in manufacture, such as sliver, roving, cops, or bobbins, are placed in perforated compartments forming the periphery of a rotary

drum. Dye and other liquors are circulated by a pump through the material, which, excepting the rotary motion, is kept at rest and so preserved from derangement. Two sheets of drawings are given; it is impossible to properly explain the mechanical arrangements apart from these.

—E. B.

## VII.—ACIDS, ALKALIS, AND SALTS.

*Nitric Acid Chlorine Processes.* G. E. Davis. Chem. Trade J. 1890, 254—256.

In 1838 Watt and Tebbutt (Eng. Pat. 7531) obtained letters patent for "improvements in the manufacture of oxides of lead, and also of carbonate of lead." Chloride of lead is treated with nitric acid, when chlorine passes off, and is passed into an apparatus such as is used in making chlorides of lime, soda, &c. This is, the author believes, the first patent in which the use of nitric acid is described for the production of chlorine. On January 11th, 1838, these same gentlemen filed another specification (Eng. Pat. 7538) in which they say that chloride of sodium is put into a firebrick oven and a certain quantity of nitric or nitrous acid added, gentle heat applied, and the chlorine liberated is passed into apparatus commonly used in forming the chlorides.

It is quite certain, adds the author, that neither of these processes could meet the requirements of the chlorine manufacture of the present day.

Nine years afterwards (March 16th, 1847) the well-known Dunlop process (Eng. Pat. 11,624) was patented. Dunlop described his invention as follows:—"My invention consists of an improved method of producing chlorine fit for manufacturing purposes, by effecting mutual decompositions between the following substances: Muriate of soda, or any other muriate, nitrate of soda, or any other nitrate, muriatic acid, nitric acid. The assistance of sulphuric acid is in some cases required. I generally prefer employing it, in order to obtain for residuum, sulphate of soda, suitable for the manufacture of soda, &c. The above substances may be employed either altogether, or only two of them; as, for instance, nitrate with a muriate (in which case, of course, sulphuric acid must be employed), or a muriate with nitric acid, or a nitrate with muriatic acid, or muriatic and nitric acids may be used together. For the latter cases sulphuric acid is employed, according to the results wished to be obtained. On the application of heat, chlorine, an oxide of azote, and muriatic acid are evolved. These gases are then passed through a suitable condenser charged with sulphuric acid of a strength sufficient to absorb the oxide of azote. The chlorine and muriatic acid are then separated by means of water." In dealing with the foregoing nitrosulphuric acid, Dunlop says, "The process I usually follow is to introduce the nitrous sulphuric acid into a suitable vessel, when by the addition of water and heat, the oxide of azote is disengaged. This latter is caused to traverse a suitable condenser along with a sufficient quantity of air and steam or water, and is by this means all transformed into nitric acid, which can be used again in the manufacture of chlorine, and again recovered in the manner described, and so on."

The year following, November 21st, 1848, McDougall and Rawson (No. 12,333, November 21st) filed a provisional specification in which the collection and oxidation of nitrous fumes from any source is described. They pass the lower oxides of nitrogen alternately into water, or an aqueous solution of nitric acid, with air containing oxygen, and this patent was actually allowed in spite of the one granted the year before to Dunlop.

Swinfells and Nicholson in 1852 (Eng. Pat. 390), patented a process for the production of chlorine, by adding nitric acid to hydrochloric acid, and heating the same so as to produce chlorine and nitrochloric acid, and this being brought into contact with oxygen gas and with the vapour of water, nitric acid is produced, and the chlorine conveyed where required.

Higgin, in 1854 (Eng. Pat. 766), in describing his invention for a mode of separating metals from each other, states that one of the liquids he prefers to employ is a mixture of muriatic acid and nitrate of soda, which yields chlorine in solution; but it is not even hinted at as being a process for the industrial manufacture of chlorine gas.

Gatty, in 1857 (Eng. Pat. 2230), proposed to employ nitrates in the manufacture of chlorine, but only as an oxidiser for the manganese, but he patented the application of the nitrous fumes for use in the manufacture of sulphuric acid, either "at once," or after they had passed through condensers.

In the year 1858 Messrs. Roberts and Dale patented a process (Eng. Pat. 2242) similar to that previously protected in 1847 by Dunlop. These inventors pursued absolutely the same methods as Dunlop for the production of their chlorine; but when the nitrogen oxides were driven off from the nitrosulphuric acid, instead of oxidising them for employment again, Messrs. Roberts and Dale conducted them into a solution of alkali.

In 1864 Messrs. Baggs and Simpson obtained provisional protection (Eng. Pat. 2313) for a process similar to that of Dunlop. It was subsequently abandoned. There is, however, one point of interest, in that the inventors, operating upon nitric acid with hydrochloric acid in a separate vessel, thought it necessary to specify that a gentle heat should be applied. Chloronitric and chloronitrous gas with free chlorine are evolved. Although Messrs. Baggs and Simpson abandoned the foregoing specification, yet it is doubtful whether it left their minds altogether, as Isham and Baggs, in 1866 (Eng. Pat. 3296), obtained letters patent for improvements in the manufacture and treatment of hydrochloric and nitric acids, which seem to bear somewhat upon the processes at which they had previously been working. These improvements were the treatment of liquid nitric or muriatic acid with sulphuric acid in order to secure the absorption of the water by the latter.

Up to this time no method essentially differing from the process of Dunlop (1847) seems to have been proposed; it is true that Baggs and Simpson preferred to bring the hydrochloric acid in contact with the nitric acid in a separate vessel, while Dunlop, as also Roberts and Dale, preferred to mix the nitrate with the salt, and to decompose both with sulphuric acid.

A period of 20 years now elapsed during which attention seems to have been riveted upon the problem of manganese recovery from the older chlorine process. On the 1st of October 1884 John Taylor (this Journal, 1885, 594), applied for provisional protection for a new process for the preparation of chlorine gas, and on the 12th of June 1885 he filed his complete specification. This specification bears a nearer resemblance to that of Baggs and Simpson than to that of Dunlop, but in the author's opinion is not identical with either. Taylor says:—"In carrying out my invention gaseous hydrochloric acid is passed through a tower or tube, or other suitable apparatus containing fragments of pumice stone, coke, or other suitable inert material, through which cold strong nitric acid is allowed to flow. The action of the nitric acid causes the formation of chlorine, nitrosyl chloride, water, and small quantities of nitrogen tri- and tetraoxides, about two-thirds of the chlorine of the hydrochloric acid being set free at once." Taylor does not give the details of the reaction, probably owing to the complications introduced by the presence of air, which always exists in very large quantity in furnace gases; but the main reaction is probably as follows:—

and the reason that two-thirds of the chlorine of the hydrochloric acid is liberated in the free state is probably because the oxygen of the furnace gases, in the presence of water, converts some of the  $\text{N}_2\text{O}_4$  into  $\text{HNO}_3$ , and this acts again before it has been removed from the sphere of action. The awkward features in this reaction are the by-products. The hydrochloric acid acts as a reducing agent to both tetra- and trioxide of nitrogen, and these, when formed, pass on with the chlorine and oxides of nitrogen. The excess of water formed during the reaction, and also that, I presume, coming from the vitriol used for decomposing the salt, is stated to

be periodically removed from the bottom of the nitric acid tower. Taylor then states that the mixed gases, chlorine, nitrosyl chloride, and nitrogen tri- and tetroxides are passed into strong sulphuric acid, which absorbs the nitrous fumes, permits the chlorine to pass on unchanged, and decomposes nitrosyl chloride with the formation of hydrochloric with which it is mixed, is sublimated a second time to nitric acid, and afterwards to sulphuric acid. The resulting gases are put through the processes a third time if necessary. The two alternations will produce a chlorine containing 90 per cent. of the hydrochloric acid as free chlorine, while three alternations produce about 96 per cent. In actual practice this chlorine is further washed with water to dissolve out the last traces of HCl.

In order to regenerate the nitric acid employed, Taylor places the nitrosulphuric acid in a suitable vessel, dilutes it by the gradual addition of water, while a rapid current of air is passed through. The nitrous vapours evolved are passed through water in a series of Woulf's bottles, whereby nitric acid of sufficient strength for use over again is obtained. (See also J. Taylor, Eng. Pat. 4201 of 1887; this Journal, 1888, 210.)

In the year 1887, William Donald obtained letters patent for an invention "to obtain chlorine from hydrochloric acid, and to recover the by-products formed during the operation" (Eng. Pat. 62; this Journal, 1887, 822; see Figs. 1 and 2). Hydrochloric acid gas is first dried by passing it through a suitable receptacle charged with sulphuric acid. The dried gas is then passed into a vessel charged with a mixture of strong nitric and sulphuric acids, where the hydrochloric acid gas undergoes decomposition. Donald represents the reaction that takes place as follows:—

The gaseous mixture resulting from the foregoing operation is now passed into a vessel containing cold dilute nitric acid, whereby nearly the whole of the oxides of nitrogen become fixed or absorbed, the reaction being expressed as follows:—

The chlorine, still containing small quantities of nitrogen compound, is now passed into a second absorbing vessel containing cold nitric acid, and finally through a scrubber containing sulphuric acid. This completes the elimination of the nitrogen compounds, and leaves the chlorine to pass on for use.

The nitric acid is regenerated by warming the nitrous liquors from the absorbers, and blowing a steady current of air through.

*Note on Concentrated Sulphuric Acid.* H. Osterberger and E. Capelle. Bull. Ind. Soc. Rouen, 1889, 307—313.

The strength of sulphuric acid of a density of 66° B. at 15° C. is given in the tables of Bineau, Bineau-Otto, and Kolb, as 100 per cent. From this it would appear that acid of 66° B. is a definite monohydrated compound. On the other hand, Winkler, Parkes, and Marignac state that the acid of such a density contains only 95 to 96 per cent. of  $\text{H}_2\text{SO}_4$ . It is, at all events, certain that the so-called acid of 66° B., as sold commercially, which tests 65.2° or 65.5° with a delicate instrument, contains some 6' or 7' more water than corresponds to the monohydrate. It may perhaps be best represented as a sesquihydrate, of the formula  $2 \text{H}_2\text{SO}_4 + \text{H}_2\text{O}$ , which consists of 91.59 per cent. of the monohydrate.

As is well known, sulphuric acid of 66° B. is obtained by concentrating acid of 60° B. in either platinum or glass stills; the latter can only be used in districts where they are obtainable at a low price, the former require a large initial outlay. Until recently, manufacturers have been content to produce with such apparatus two qualities of acid, namely, ordinary acid of 66° B. and a better quality, stated to be of the same strength, but actually marking 65.8° B. and containing 93.5 to 94 per cent. of  $\text{H}_2\text{SO}_4$ . Some manufacturers, by replacing the leaden evaporating pans by pans made of platinum and by making some other

improvements, have succeeded in producing an acid of a strength of 97 to 97.5 per cent. as determined by analysis. But the manufacture is hampered with difficulties, the wear and tear of the plant is considerable; for example, 5 to 7 grms. of platinum are lost per ton of the 97 per cent. acid made as against 1 or 2 grms. per ton in the concentration of the ordinary acid. Recently, however, Lunge has patented another process for the manufacture of the monohydrated acid in which the drawbacks connected with the older manufacturing process are not met with. This process depends upon an observation made by Marignac, namely, that on freezing ordinary concentrated sulphuric acid, the monohydrated acid separates in crystals. As actually carried out at Petit-Quevilly, at the establishments of the Malétra Company, who have obtained the monopoly for France, the process consists in first concentrating the acid as far as possible in the ordinary way. An acid containing from 93 to 98 per cent. of  $\text{H}_2\text{SO}_4$  is thus obtained. It is, however, preferable to operate upon acid containing, say, 97 per cent. of  $\text{H}_2\text{SO}_4$ , as the mother-liquors then contain still 94 or 95 per cent. of acid, and may be sold as such or be concentrated again. The concentrated acid is collected in a reservoir fixed above an iron vessel used for filling the crystallising cells. A pipe, provided with a tap, connects the reservoir with the filling-machine. The filling-machine is closed by an air tight cover, and divided by vertical partitions into the same number of compartments as there are crystallising cells in a set. Each compartment is connected with a corresponding cell by a pipe, whose end almost touches the sloping bottom of the compartment, and which passes through the cover vertically upwards to a height slightly above the level of the acid in the reservoir, then bends round and finally ends above the crystallising cell. When the cells are not being filled, the exposed end of the pipe is closed by a dripping vessel. Compressed air is forced into the filling-vessel in order to drive the acid into the crystallising cells. The capacity of the filling-machine is such that a set of the crystallising cells is exactly filled each time the machine is emptied; for instance, if there be 13 cells in a set, each capable of holding 12.5 kilos. of acid, the machine will contain exactly 162.5 kilos. The cells are placed in a solution of calcium chloride, cooled by a refrigerating machine to -20° C.

The blocks of acid so obtained are next loosened from the sides of the cells by dipping the latter for an instant in hot water. The blocks are collected in a trough, broken up by means of an archimedean screw, drained in a hydro-extractor, melted, and packed for transport, 100 per cent.  $\text{H}_2\text{SO}_4$  being so obtained.—E. B.

*On Thiosulphates.* A. Foek and K. Klüss. Ber. 23, 534—541.

In this paper the crystallographical measurements of the salts described are fully given.

When prepared by the authors, manganese thiosulphate did not crystallise (cf. Vortmann and Padberg, Ber. 22, 2641), the oily, rose-coloured liquid decomposing, both in the mother-liquor and *in vacuo* over sulphuric acid, into manganese sulphite and sulphur.

Cadmium thiosulphate,  $\text{CdS}_2\text{O}_3 \cdot 2 \text{H}_2\text{O}$  (*loc. cit.*) forms small, colourless, concentrically grouped, monosymmetric crystals, which do not lose water *in vacuo* over  $\text{H}_2\text{SO}_4$ , but gradually become yellow when kept from formation of cadmium sulphide. When heated in a closed tube it decomposes according to the equation—

*Potassium ammonium thiosulphate*,  $\text{K}(\text{NH}_4)\text{S}_2\text{O}_3$ , is obtained by fractionally crystallising a mixture of equal mols. of the two components from water; it forms small lustrous monosymmetric crystals.

*Potassium ethyl thiosulphate*,  $\text{SO}_2 \cdot \text{SC}_2\text{H}_5 \cdot \text{OK}$ , is formed when the preceding salt and ethyl bromide (equal mols.) are heated together in a reflux apparatus; it crystallises in slender, colourless, monosymmetric needles.

*Potassium magnesium thiosulphate*,  $\text{K}_2\text{S}_2\text{O}_3 \cdot \text{MgS}_2\text{O}_3 \cdot 6 \text{H}_2\text{O}$  (cf. Rammelsberg, Chem. Abhandl. 1888), separates from a

solution of its components in water when concentrated by a gentle heat, in large transparent monosymmetric crystals; it does not deliquesce in air.

Ammonium magnesium thiosulphate—

(Kessler, Pogg. Ann. **74**, 283) forms long monosymmetric prisms stable in air and *in vacuo* over sulphuric acid.

—A. G. B.

*The Valuation of Fuming Sulphuric Acid.* B. Setlik. Chem. Zeit. **13**, 1670.

See under XXIII., page 417.

*A New Process for Manufacturing Potassium Ferrieyanide.* G. Kassner. Chem. Zeit. **13**, 1701—1702.

Of the several methods that are available for converting ferrocyanide into ferrieyanide on the large scale, that involving the use of chlorine is usually employed on account of its cheapness, but there are objections to its use. Especial precautions have to be taken to avoid the introduction of any excess of chlorine over that required to complete the reaction, otherwise the ferrieyanide produced will suffer decrease both in quantity and quality. Another drawback to the use of chlorine is the occurrence of spontaneous explosions in the vessels containing the materials during the oxidation, due, as is commonly explained, to the formation of chloride of nitrogen. These inconveniences could be avoided by the use of peroxide of lead, but the cheapest means of producing that substance has been still too expensive hitherto for competing with chlorine as the oxidising agent. But a recent invention of the author's has made the use of lead peroxide practicable in the form of calcium plumbate, which is easily obtained by roasting oxide or carbonate of lead with calcium carbonate at a low red heat. In the conversion of potassium ferrocyanide into ferrieyanide by means of lead peroxide a quantity of potassium hydrate is set free which must be neutralised in some way before the reaction can go on to completion, and carbonic acid suffices for the neutralisation. The author's process consists in adding calcium plumbate to a solution of potassium ferrocyanide and passing a stream of carbonic acid gas when the reaction proceeds according to the equation—

The carbonates of lead and calcium separate as an insoluble precipitate which can be filtered off and regenerated by a simple roasting, whilst the solution contains potassium ferrieyanide in a pure form and potassium carbonate as a valuable by-product. The author considers that the intrinsic merits of potassium ferrieyanide as an oxidising agent in alkaline solution will occasion an extensive demand for it when its production has become sufficiently cheap. (See this Journal, 1890, 187.)—G. H. B.

#### PATENTS.

*Improvements in the Production of Chrome Preparations.* H. A. Seegall, Berlin, Germany. Eng. Pat. 4602, March 16, 1889. 6d.

THE chrome mineral is heated with an excess of an alkaline bisulphate in closed vessels furnished with mechanical stirrers, the sulphurous and sulphuric anhydrides evolved being passed first through condensers and then through milk of lime. It has been found that when some substance, such as barium sulphate, is present in the mixture, the amount of the acid vapours is very much reduced or practically disappears. The patentee explains this by supposing that when a mixture of the ore and bisulphate alone is taken the ore is apt to sink to the bottom and to remain unacted upon, whilst the bisulphate is decomposed at the temperature employed, about 600° C., with the evolution of sulphuric anhydride. When the barium sulphate is added the mass is much more pasty than before, and as the powdered ore is no longer able to sink to the bottom the sulphuric anhydride evolved from the bisulphate comes into more intimate contact with the ore, and is retained. The

chromium sulphate formed is dissolved out with water, and the chromium can be precipitated by the addition of caustic alkalis, &c. The precipitate so thrown down can be readily dissolved in various acids forming the required salts.

—S. G. R.

*A Method of Treating Waste or Spent Sulphuric Acid Pickle produced in the Manufacture of Tin, Terne, and Black Plate.* S. Daw, Llanelli, Eng. Pat. 4701, March 18, 1889. 4d.

See under X., page 395.

*Improvements in or relating to obtaining Chlorine.* R. Dormer, Garston. Eng. Pat. 5225, March 26, 1889. 6d.

IN preparing chlorine by treating manganese dioxide with hydrochloric acid, half the available amount of chlorine is lost as manganese chloride. In order to avoid this loss the patentee adds sulphuric acid to the mixture of the peroxide and hydrochloric acid, whereby the whole of the chlorine is obtained in the free state, the manganese being converted into the sulphate. As this salt is not applicable for the regeneration of the manganese, there is added to a solution of it chloride of calcium liquor, when calcium sulphate is precipitated and manganese chloride formed. This can be treated in the usual way by the Weldon process. It is pointed out that in order to recover the whole of the chlorine the only extra expense is that of the sulphuric acid used.

—S. G. R.

*Process of Manufacture of Potassic and Sodid Hydrates and of By-products.* G. A. H. Gabet, Paris, France. Eng. Pat. 5341, March 28, 1889. 6d.

A dilute solution, about 15 per cent., of the acid phosphate of calcium, is treated with sulphate of sodium or potassium, the calcium being thus precipitated as sulphate. To the solution milk of lime is added with the separation of calcium phosphate, and the formation of the hydrates of potassium and sodium. The double salts of potassium, sodium, and magnesium may also be used with advantage. The acid phosphate of magnesium being soluble it can, when required, be either precipitated mixed with calcium phosphate by the addition of milk of lime, or it may be obtained pure by adding potash solution, and then, after its precipitation, the remaining phosphoric acid in combination with the potash may be precipitated as before by adding milk of lime. Very pure caustic soda may be prepared by precipitating a part of the phosphate with milk of lime, and then crystallising the disodium phosphate before its final treatment with milk of lime.—S. G. R.

*Improvements relating to the Treatment and Utilisation for Agricultural and other Purposes of Bisulphate of Soda or "Nitre Cake."* H. J. Kirkman, Swansea. Eng. Pat. 5703, April 3, 1889. 4d.

IT is proposed to use the acid sulphate of soda, produced in the manufacture of sulphuric and nitric acids, as an absorbent for the ammonia from gas liquor instead of the sulphuric acid customarily employed. Or the salt may be dissolved in the gas liquor and the resulting solution crystallised to obtain sulphate of soda and sulphate of ammonia.—S. G. R.

*A Process for Producing Cupr-Ammonia.* C. F. Hime, London, and J. H. Noad, East Ham. Eng. Pat. 7716, May 8, 1889. 4d.

SCRAP copper is placed in a vessel containing ammonia solution. The copper is in connexion with the one pole of a battery, whilst attached to the other are electrodes placed in porous vessels which are plunged into the alkaline liquid. On passing the electric current the copper dissolves in the ammonia forming "cupr-ammonia."—S. G. R.

*Improvements relating to the Production of White Lead.* H. H. Lake, London. From J. B. Tibbitts, Hoosac, U.S.A. Eng. Pat. 18,076, November 12, 1889. 6d.

See under XIII., page 398.

*A Method of and Apparatus for obtaining Ammonia from Atmospheric Nitrogen and the Hydrogen of Decomposed Steam.* J. C. Fell, London. From the American Ammonia Manufacturing Co., Alexandria, U.S.A. Eng. Pat. 20,722, December 24, 1889. *8d.*

By strongly heating together an alkali and carbon in the presence of nitrogen an alkaline cyanide is produced which

when brought into contact with air is oxidised with the formation of a cyanate. On treatment with steam the cyanate is decomposed with the production of ammonia, oxides of carbon, hydrogen, and various alkaline compounds. From this mixture ammonia is readily separated by passage through suitable scrubbers.

The operations are carried out in two different forms of apparatus. In one case (Figs. 1 and 2), the ammonia-generating furnace A is heated by the introduction of gas and air by the pipes C and D into the combustion chamber B. Through the hopper E is fed in the mixture of carbon and alkali which becomes intensely heated as it falls upon the baffle plates F in the furnace, and in combination with the nitrogen present forms cyanides. H is a superheater by means of which the oxidising current of air entering at I and the decomposing current of steam J are raised to a high temperature, their action being as already mentioned above. The air pipe is placed above the steam pipe so that time may be allowed for complete oxidation.

In the second form of apparatus, Fig. 3, A is the furnace in which the fuel is burned, furnished with an air inlet d, and in connexion with the ammonia-generating vessel e there is no special air supply tube, but steam is injected through the superheater g. B serves as a separator for any solid matter escaping from A, whilst in C the gases are cooled before the separation of the ammonia. D is a scrubber to remove the alkaline salts present with the ammonia. The condensing liquors used retain a little ammonia which is given off when boiled in the vessel E, whilst F is the scrubber or series of scrubbers in which the ammonia is intercepted.—S. G. R.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

*Enamelled Lava as a New Ceramic Material.* Gillet. Deut. Töpfl. u. Ziegl. Zeit. **20**, 783.

ENAMEL-PAINTING on lava, discovered by Mostelique, has lately been extended by the author to building ornaments, vessels for chemical works, and wall painting. The natural product, which was formerly used in its crude state, is now powdered and mixed with some binding material so as to form a malleable paste which can be modelled and burnt without cracking, as when dried it shrinks only slightly. It is very hard. The enamel is applied as usual with ceramic objects.—N. H. J. M.

*A New Coral Red.* Deut. Töpfl. u. Ziegl. Zeit. **20**, 796.

THIS is a colour for porcelain or stone-ware prepared as follows:—Lead chromate (20·40 parts), minium (67·83 parts) and quartz (12·27 parts) are melted together until clear. The dark red substance is powdered and used with the hard colourless flux I, or with the soft flux II.

Flux II. Minium (80 parts), quartz (20 parts); flux I. minium (80 parts), quartz (100 parts), crystallised boric acid (20 parts).

The fluxes are melted clear, powdered, and rubbed on the pallet. A good coral-red is obtained by rubbing the colour (75 parts) and one of the fluxes (25 parts) on the pallet, and laying it on to the object with turpentine and thick oil.—N. H. J. M.

*The Tarnishing of Glass during Manufacture.* Moritz. Sprechsaal, **22**, 943.

DURING the flattening-out of window-glass on gas-furnaces the surface of the glass is corroded or tarnished by the action of the flame; and it is usual to remove this tarnish by bathing the separate sheets in some fluid, such as dilute hydrofluoric acid. This operation is a very tedious one, and according to the author may be avoided by supplying the gas-furnace with cold air only, instead of heated air, as is usually done. By this means a more or less sooty flame is produced which does not injuriously affect the glass.

—H. T. P.

### PATENTS.

*Improvements in the Manufacture of Blocks of Terra-cotta and like Materials, and in Machinery for this purpose.*

H. L. Doulton and S. H. Leech, Lambeth. Eng. Pat. 5205, March 26, 1889. *8d.*

OWING to the great difficulty of drying large blocks of terra-cotta it is necessary to make them hollow, and hitherto they have had the form of hollow casings or shells which have to be filled when used for building purposes in order to possess the necessary strength and solidity. According to the present invention the blocks are formed with a number of internal cells or cavities similar to the well-known perforated bricks, but that the cavities are only open at one end, the closed end forming part of the face of the block. The cellular structure allows of complete drying of the clay whilst the block remains practically solid and requires no filling. Such blocks can be made in a variety of ways, and the machine shown in the drawings serves to illustrate the principle involved which especially provides for the admission of air into each cavity at the moment of formation, so that each cavity is prevented from collapsing by the enclosed plug of air. The machines may be constructed to deliver the clay in a continuous block to be cut to required lengths and faced by hand, or the block may take its final form in the machine.—G. H. B.

*The Use of Sugar in the Manufacture of Fire-clay Goods.* G. Palin, Kildgrove. Eng. Pat. 7387, May 3, 1889. *4d.*

ABOUT 3 per cent. of unrefined or raw sugar from beet root or sugar cane is added to the gannister sand or fire-clay used in the manufacture of fire-bricks, furnace linings, seggars, tiles, &c. The result is said to be that the materials, after baking, possess particularly good fire-resisting qualities.

—E. G. C.

*Improved Process and Furnace for the Preparation of Crude Glass, according to Leuffgen's Method, by the combined use of Water-Gas, Coal-Gas, Wood-Gas, Oil-Gas, or Natural Gases, and Generator-Gas.* J. Quaglio, Berlin, Germany. Eng. Pat. 7659, May 7, 1889. *8d.*

THE arrangement consists of a tank-furnace heated by gaseous fuel, and on the roof of the furnace are melting pots with a lateral opening at the bottom, the contents of which are slowly but continuously melted by the action of a blow-pipe flame impinging on the edge of the materials. The fused crude glass, called calcin, runs down a gutter to a shallow receptacle, from which it overflows into the main tank to be drawn off as required. The refining of the crude glass is accomplished by the action of the flame playing on the stream of glass on its way through the furnace.

—G. H. B.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*Valuation of Roofing Slates.* H. Brunner. Schweiz. Wochenschr. f. Pharm. 1889.

THE specific gravity and the colour are no criteria of the value of a slate: the true markings or lines which are most easily seen by holding the slate in a slanting position close to the eye, should run parallel to the long axis, otherwise the slate will break easily. A good slate must be hard, should not be easily scratched with the finger nail, should not break into laminae, and should give out a clear note when struck.

The presence of calcium carbonate, pyrites, and marcasite can be easily detected by examining a thin fragment with a polarisation microscope.

For examining the absorptive qualities, a piece of slate 12 centimetres long and 6 centimetres broad is placed in a beaker containing water 1 centimetre in depth, the beaker is covered with a glass plate and left for 24 hours; at the end of this time, if the slate is a good one, only a few millimetres above the level of the water will be damp.

In examining slates chemically the calcium carbonate (magnesium carbonate) and the sulphide of iron are estimated in the usual way, and the weathering qualities, which are of the greatest importance, are examined by R. Fresenius' method (Zeits. Anal. Chem. **7**, 72).

The action of heat and cold should also be tried: for this purpose the slate is saturated with water and then placed for 24 hours in a freezing mixture. Another sample is heated at 250°—300° for five to six hours and then placed in water.

For an approximate determination of the commercial applicability of a slate it is treated with hydrochloric acid; a brisk effervescence indicates a bad, calcareous slate. Another portion is heated in a glass tube; a yellow sublimate of sulphur and evolution of sulphur dioxide indicates a bad slate.—F. S. K.

*The Examination of Roofing Slates.* F. Reverdin and C. de la Harpe. *Chem. Zeit.* **14**, 61—65, 94—95, and 126—127.

H. BRUNNER (preceding abstract) has described methods for judging the quality of roofing slates, and the authors criticise his conclusions and advance their own. Of the physical properties of a slate, such as its specific gravity, tenacity, elasticity and porosity, Brunner considers the last of greatest importance, and determines it thus: A test-piece is placed in a beaker and water poured in to the depth of 1 cm. After 24 hours the height to which the water has risen on the test-piece on account of its capillarity is read; the better kinds of slate give a smaller rise than those inferior to them. The authors doubt whether this is of much value on Brunner's own figures, as a sample reported "bad" by him gave a rise of 3 mm., and one stated to be "very good" a rise of 4.5 mm.

The chemical constitution and behaviour of slates are however the data to which Brunner attaches most weight, and the chief tests he uses are the determination of the quantity of calcium carbonate and pyrites in the sample and its power of resisting the action of sulphurous acid. The authors dissent from this view on the several grounds that slates of known excellence, such as that from Morzine, may contain as much as 49 per cent. of calcium carbonate, while other specimens (*e.g.*, from Servoz) free from that substance may be of poor quality; that the same observation applies in the case of pyrites, and that further pyrites, when present, appears to suffer no change on exposure of a slate to weather; that the use of sulphurous acid to imitate the disintegrating effect of exposure though convenient lacks precision, and is only of limited usefulness.

The methods and conclusions adopted by the authors are as follows:—The agencies by which the deterioration of slates is effected are—

(1.) Chemical action of the atmosphere (weathering).

This is comparatively of small importance.

(2.) Chemical action of gases arising from the wood work beneath the slates.

(3.) Physical action of changes of temperature favoured by the dissimilar conductivity of heat of slate in the direction of and at right angles to its plane of cleavage.

This is considered the most weighty of the three.

The samples examined included slates of various origins, *e.g.*, Sembrancher, Salvan (grey), Salvan (black), Outre-Rhône, Mex, Morzine, Servin, Angers, Ardennes, both old and new specimens; Orny, Sion, Saxon, Isérable, Pfeffers, La Chambre, Le Plet, new only.

The methods used were:—

(1.) *Determination of Porosity after the Action of Acids.*

—Test-pieces 6 cm.  $\times$  2 cm.  $\times$  ? were treated with 10 per cent. acetic acid in the cold, the flask containing them being rendered vacuums from time to time, until the evolution of carbon dioxide ceased—a result sometimes taking weeks to attain. The extracted pieces were then washed, dried, weighed, and immersed in diphenylamine (m.p. 54° C. b.p. 310° C.) contained in a thick-walled tube 12 cm.  $\times$  3.5 cm. The tube was exhausted, heated for two hours in an oil-bath at 170° C., the air pressure restored, and the heating continued for 4—5 hours at 150° C., after which the test-pieces were removed, the diphenylamine clinging to their surface wiped off (the wiping being supplemented by rapid washing with ether), and the increase in weight taken. Some figures thus obtained are: Salvan, 0.05; Outre-Rhône, 0.08; Sembrancher, 0.15; Orny, 0.22; Pfeffers, 5.8; La Chambre, 9.2 parts per cent. respectively.

(2.) *Determination of Soluble Ferrous Iron.*—The finely powdered samples were digested with acids, such as acetic and hydrochloric, and the ferrous salt extracted determined colorimetrically. Old and new specimens of the same slate gave similar quantities of iron in the ferrous state, showing that oxidation by exposure to weather was trifling.

(3.) *Determination of the Porosity of Old and New Slates.*—The method used was similar to that described

under (1) save that the test-pieces were not extracted with acetic acid. Some of the results are given below:—

Name.	New.	Old.	
	Increase in Weight.	Age.	Increase in Weight.
	Per Cent.		Per Cent.
Salvan (grey).....	0.03	45	0.19
Outre-Rhône.....	0.02	10	0.06
Ardennes.....	0.03	30	0.15
Sembrancher.....	0.04	10	0.28
Angers.....	0.06	30	1.11
Morzine.....	0.02	30	1.18
Mex.....	0.04	30	0.31
Salvan (black).....	0.06	..	..
Orny.....	0.09	..	..
Sion.....	1.15	..	..
Servin.....	..	20—25	1.16
Unknown (much disintegrated).	..	..	2.58

From this it appears that new slates are considerably less porous than old, and that the rate of increase in porosity is much higher in some specimens than in others.

(4.) *Resistance to the Effect of Rapid Alterations of Temperature.*—Test-pieces 6 cm.  $\times$  2 cm.  $\times$  ? were heated in a wrought-iron tube for half an hour to 300° C., and the tube then suddenly cooled by a stream of water for half an hour; the process was repeated 24 times, after which the test-pieces were impregnated with diphenylamine as described above, with the following results:—

Name.	Increase in Weight after Treatment.	Increase in Weight of Untreated Specimens.	Difference.
Outre-Rhône.....	0.08	0.02	0.06
Salvan (black).....	0.13	0.06	0.07
Sembrancher.....	0.12	0.04	0.08
Mex.....	0.15	0.04	0.11
Orny.....	0.27	0.09	0.18
Morzine.....	0.24	0.02	0.22
La Chambre.....	0.74	0.60	0.14
Sion.....	2.35	1.15	1.20

In the light of these investigations, the authors conclude:—That the valuation of a slate can be best arrived at by determining its porosity when new and after having been subjected to alterations of temperature. A high degree of porosity when new, or a considerable increase after repeated heating and cooling, condemns a slate. Though not laid down as absolute limits, the authors consider that the porosity of a good slate when new should be below 0.1 per cent., and after treatment less than 0.2 per cent.—B. B.

#### PATENTS.

*An Improved Non-corrosive Material, suitable as a Cement Packing or Covering to Resist Acids.* B. Rhodes, London, Eng. Pat. 5363, March 28, 1889. 4d.

The composition is made by mixing specified quantities of mica, talc, "flower of sulphur," and asbestos fibre with india-rubber, asphaltum, and "albo-carbon" dissolved in

mineral spirit, the whole forming a dough which may be applied to the purpose required. In some cases the solvent may be omitted and vulcanisation effected by heating.

—G. H. B.

*Improved Combination of Ingredients for Use as Mortar, Plaster, and the like for Building Purposes.* T. K. Ferguson, Forest Hill. Eng. Pat. 5412, March 29, 1889. 4d.

SPECIFIED proportions of clay, sand, plaster of Paris, and quicklime are mixed together along with water and a small quantity of vitriol to form the mortar.—G. H. B.

*Improvements in the Manufacture and Composition of Refractory or Fire-resisting Cement or Cements.* W. S. Lea and H. M. Lynam, Hanley. Eng. Pat. 5919, April 6, 1889. 6d.

THE materials composing the two cements are given as follows:—

	No. 1.	No. 2.
	Parts.	Per Cent.
Disintegrated granite.....	20	50—65
Blast furnace or basic steel slag.....	50	5—15
Steatite.....	32	15
Silica, siliceous ochre.....	32	5
Kaolin.....	60	..
Phosphate of lime.....	40	5
Loam.....	24	..
Argil.....	32	..
Sodium chloride.....	8	2
Calcium carbonate.....	8	2
Caustic potash.....	4	1

The powdered mixture is made into a plaster with water to be used as a lining for furnaces. It should be applied in several coats to a thickness of half an inch. It withstands rapid changes of temperature without disintegration. The disintegrated granite is prepared by exposing the intensely heated rock to the action of gaseous nitric and hydrochloric acid, with subsequent reduction to powder.—G. H. B.

*Improvements in Machines for the Manufacture of Bricks and Briquettes.* N. Procter, A. Middleton, C. E. Fraser, and H. M. Carter, Leeds. Eng. Pat. 8845, May 28, 1889. 6d.

THE invention relates to the automatic measurement of the materials entering any brick-making machine. For this purpose the charging hopper is placed above a revolving drum having a diametrical channel for the passage of the materials, its function resembling that of the plug in an ordinary tap. But the fall of the materials is checked by a metal piston sliding freely within the channel. At each revolution a portion of material enclosed in the channel is carried round, and when the piston is uppermost it presses the charge downwards into the machine, giving room for a fresh charge from the hopper. The quantity of material to be delivered may be adjusted by altering the size of piston.

—G. H. B.

*An Improved Composition or Plaster for the Treatment of Walls and the like.* J. B. King, West Brighton, Rd., U.S.A. Eng. Pat. 10,997, July 9, 1889. 4d.

THIS compound consists essentially of a restraining material (preferably glue), a ground stone or stone-like material (marble, chalk, plaster, slaked lime, &c.), and a fibrous material (preferably asbestos).—E. G. C.

## X.—METALLURGY.

*Chemical Society of Hamburg.* Chem. Zeit. 13, 1706.

A BRIEF notice of a report presented by Dr. Gilbert of his journey to the Rio Tinto mines. After some remarks of historical interest there followed a description of the disposition of the strata and the methods of working the ores. In the year 1888 one and a half million tons of ore were worked yielding 20,000 tons of copper. The ores contain on the average 49 per cent. of S., 43 per cent. of Fe, 3 per cent. of Cu, 1 per cent. of PbO, "6 per cent. of As," and 2 per cent. of SiO<sub>2</sub>, with small quantities of gold, silver, bismuth, tin, antimony, nickel, selenium, and thallium. The burnt ores from the vitriol works are worked up for copper, gold, silver, and recently also for bismuth, the residual iron oxide going to ironworks.—G. H. B.

## PATENTS.

*Improvements in the Manufacture of Metallic Alloys.* G. A. Dick, London. Eng. Pat. 2484, May 25, 1882. Amended December 4, 1889. 6d.

THE patentee now restricts his claims to the manufacture of alloys "by introducing into copper zinc and copper zinc and tin alloys definite quantities of iron by previously causing the zinc uniformly to dissolve or absorb a known proportion of iron." The three other claims in the original specification relating to the reduction of oxides by means of "manganese copper," and to the production of alloys containing, in addition to the above metals manganese or lead, being withdrawn.—O. H.

*A New or Improved Method of Coating Plates and Sheets of Iron with Copper or Brass, and Apparatus to be Employed in effecting the said Coating.* W. E. Everitt, Birmingham. Eng. Pat. 4335, March 12, 1889. 6d.

THE sheet of iron is cleaned by "pickling" or otherwise, and an even layer consisting of a mixture of about equal parts of granulated solder and powdered borax sieved over the surface. Upon this the sheet of copper or brass is laid and the plates placed in a heating furnace when the solder and borax are melted. The plates are then passed between rolls.—J. B. C.

*A Method of Treating Waste or Spent Sulphuric Acid Pickle produced in the Manufacture of Tin, Terne, and Black Plate.* S. Daw, Llanelly. Eng. Pat. 4701, March 18, 1889. 4d.

IN order to clean the iron plates they are immersed in dilute sulphuric acid, a solution of sulphate of iron being thus produced. To this is added magnesium oxide and the whole warmed, when iron oxide is precipitated with the formation of magnesium sulphate. The liquors may be then concentrated and crystallised. Instead of magnesium oxide, dolomite in the proper proportion may be used.—S. G. R.

*Improvements in the Manufacture of Artificial Cryolite.* M. Netto, Newcastle-on-Tyne. Eng. Pat. 6668, April 18, 1889. 4d.

THE residual slags left after the extraction of the aluminium consist in the main of sodium fluoride and chloride. To a strong solution of these there is added a hot concentrated solution of hydrated aluminium sulphate, when aluminium fluoride is precipitated. This is removed and mixed with more of the slag, either in a solid condition or else in the form of a strong solution. On fusion an artificial cryolite is obtained.—S. G. R.

*Improvements in the Manufacture of Steel.* W. F. Jackson, Litton, and W. Gallraith, Stoke-on-Trent. Eng. Pat. 7047, April 27, 1889. 8d.

THE object of the invention is to regulate the quality of the steel manufactured from phosphoric irons by the "basic" Bessemer, Siemens, or open-hearth process. The molten charge when sufficiently decarbonised and dephosphorised is teemed into the ladle either with or without a previous partial addition of hematite iron, spiegeleisen, ferromanganese or other alloy. The charge is run from this ladle into a second ladle, simultaneously with a charge of molten spiegeleisen, ferromanganese, or other alloy, and a suitable quantity of molten silicious slag, and teemed into moulds from the second ladle.—J. B. C.

*Improvements in Means for effecting the Separation of Particles of different Specific Gravities, more especially intended for the Separation of Gold and other Metals from Crushed or Divided Ores.* M. Crawford, Liverpool. Eng. Pat. 8789, May 27, 1889. 8d.

THE invention consists of an apparatus or machine, which holds a number of troughs arranged in tiers. The bottom of each trough is inclined, the inclination being opposed to the flow of a stream of water, which is allowed to flow over the bottom. At the same time the troughs are attached to spring hangers and are moved by an eccentric, which imparts a sideways movement. The troughs can be readily removed for cleaning.—J. B. C.

*Improvements in Machinery or Apparatus for Extracting Precious Metals from their Ores.* D. Dumes and T. K. Rose, London. Eng. Pat. 19,622, December 6, 1889. 8d.

THE finely divided ore is injected by air into a muffle where it meets with a current of water-gas, and the ore thereby roasted. From the muffle the roasted ore is fed into a chlorinating apparatus consisting of a drum or cylinder lined with lead and revolving on hollow trunnions. Through the hollow trunnions the chlorine gas is driven out by compressed air, when the extraction is complete. The contents of the drum are discharged into a conical leaching vat, the bottom or filter bed of which is movable, and by compressed air the liquid is forced through the filter bed. The filter bed may then be lowered and the contents of the vat discharged into a hopper and conveyed away. The solution of the precious metal is forced through a filter press containing an insoluble sulphide (either of iron or copper), which precipitates the precious metal.—J. B. C.

*Improvements in Calcining and Refining Copper Ore, Copper Regulus and Copper Precipitate, and in the Construction of Furnaces therefor.* F. W. Dähne, Swansea. Eng. Pat. 1641, January 30, 1890. 6d.

THE improvement consists in calcining "white metal" containing about 75 per cent. of copper in a suitable furnace by its own heat of oxidation. The calcining furnace, which is included in the patent, has several horizontal circular beds arranged in tiers and enclosed in rectangular brickwork. Each bed is provided with a mechanical rake, all the rakes being worked by a common shaft. Air may be admitted through the central core of the shaft to each bed of the furnace as well as by suitable openings in the walls. Heat is maintained by combustion of the sulphur. The calcined ore is mixed with 6–8 per cent. of carbon and also with suitable fluxes, and refined in the ordinary way. The "blister copper" process is avoided and arsenic and other impurities are expelled.—J. B. C.

*Improvements in Apparatus or Machinery for Coating Metal Sheets with Metals or Alloys.* R. Heathfield, Darlaston. Eng. Pat. 1682, January 31, 1890. 8d.

THE patent has special reference to the feed and exit rolls in connexion with a galvanising pot. The rolls are boxed in so as to keep them as much as possible out of contact with the surface scum. The rolls may be fixed above or below the surface of the molten metal, and the feed and exit rolls may be inclined at any angle required or readily removed from the pot.—J. B. C.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### PATENTS.

*An Improved Apparatus for Economically Effecting the Double Decomposition of certain Substances by the Aid of Electricity.* W. H. Dowland and W. Mills, London. Eng. Pat. 2331, February 9, 1889. 6d.

TO obtain the whole of the products of the decomposition of haloids, the chief of which is common salt, a special apparatus is employed consisting of a rectangular vessel divided by porous partitions into three compartments, the two outer of which can be covered with gas-tight covers of convenient form with pipes let into them to allow of any gases being carried away. The central compartment and one of the outside ones are filled with a saturated solution of common salt, and in this outside compartment is also placed the positive electrode of, say, carbon, while the other compartment contains the negative electrode in a solution of caustic soda. On the passage of an electric current through the bath, hydrogen is given off at the negative electrode and chlorine at the positive.—B. T.

*Improvements in the Form and Manufacture of Secondary Battery Frames and Plates.* A. Douglass and F. Smith, London. Eng. Pat. 2544, February 13, 1889. 6d.

THESE frames are cast with V, U, or half-round inside edges in order to retain the active material, spun-glass being mixed with this latter to assist its adhesion; lead wire can also be laced backwards and forwards in a sort of trellis-work for the same purpose.—B. T.

*Improvements in the Extraction of Copper and Zinc from their Ores, as also of the Precious Metals contained therein by Electrolysis, and Apparatus therefor.* C. D. Abel, London. From Siemens and Halske, Berlin, Germany. Eng. Pat. 3533, February 27, 1889. 8d.

THE pulverised ore, together with a solution such as ferrie sulphate, is introduced into long narrow channels arranged in a zigzag fashion, each channel containing two cylinders of suitable material carrying vanes or paddles on their surfaces and caused to rotate by mechanical means, adjacent cylinders rotating in opposite directions, so that the ore, although of higher specific gravity than the liquid, is held in suspension. The temperature of the solution is maintained at any desired point by means of steam pipes passing along the channels. If the amalgamation process be used the steam pipe is replaced by a rotating copper cylinder, the lower part of which dips into mercury in order to keep it amalgamated, and the paddles cause the ore to impinge upon the cylindrical surface, or a salt such as potassium cyanide is added to the liquid and an electric current is sent through the bath to precipitate the precious metal, the copper cylinder serving as the cathode. To regenerate the sulphate of copper solution and to remove the copper it is passed into a cell containing rotating

cylinders as cathodes, on which the copper is deposited, while the solution gradually sinks down through a filtering arrangement past the horizontal anode and is converted into ferric sulphate and is again ready for use.—B. T.

*Improvements in the Preparation of Bleaching Agents.* D. G. FitzGerald, Brixton. Eng. Pat. 5995, April 8, 1889. 6d.

THE patentee has previously described (this Journal, 1887, 515) a process for the regeneration of chromic acid from spent solutions. He now adds to the solution thus obtained sulphuric and hydrochloric acids. Chlorine is given off and may be passed into water or into an aqueous solution containing some base in solution or in suspension within it. The chromium sulphate formed may be electrolysed, chromic acid being produced, but on a further continuance of the electrolytic action, oxygen is evolved which may, together with the chlorine, be used for bleaching purposes.—S. G. R.

*Improvements in the Accumulation of Electrical Energy and Apparatus therefor.* F. Marx, Berlin, Germany. Eng. Pat. 9496, June 7, 1889. 8d.

INSTEAD of using electrodes which become chemically changed during charging and discharging, a solution is employed which alone undergoes alteration, while the carbon electrodes are unaffected. This fluid is termed "electrolin" and may be made up of 450 grms. protochloride of iron, 900 grms. of water, 500 grms. of hydrochloric acid. During the passage of the electric current the protochloride is converted into perchloride of iron. For the discharge, one electrode consists of a metal such as iron and the other of carbon. Salts of copper may also be similarly utilised.—B. T.

*Improvements in Secondary Batteries.* C. H. Logan, Detroit, U.S.A. Eng. Pat. 19,861, December 10, 1889. 8d.

VARIOUS methods of connecting up the plates are described in which wedges are used to produce the required pressure between the contact pieces, or the connecting pieces dovetail into one another. A frame of non-conducting material notched to hold the plates and provided with india-rubber cushions is also shown.—B. T.

*Improvements in Plates for Secondary Voltaic Batteries.* C. H. Logan, Detroit, U.S.A. Eng. Pat. 19,861A. December 10, 1889. 6d.

To present large active surface with contrivances for holding the active material, the lead frames are cast with vertical tubular slots in them closed at the bottom, or with curved or diamond-shaped pockets.—B. T.

*An Improved Method of and Means for the Production of the Grids of Electric Accumulators in which the Bars narrow from each side inwards.* E. Correns, Berlin, Germany. Eng. Pat. 20,235, December 16, 1889. 6d.

THESE plates are formed of a lead framework with square or suitably shaped apertures, across which apertures are cast cross-shaped pieces of triangular section with their apices pointing inwards so as to better retain the active material.—B. T.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

*Electrical Phenomenon in a Ceresin Manufactory.* B. Laeh. Chem. Zeit. 13, 1671.

TOWARDS evening, in a manufactory of stearin and ceresin in Italy, four tanks holding about half a ton each of white ceresin, were being stirred to assist the cooling. Suddenly the electric lighting accidentally failed, leaving the workroom in darkness, when the workmen were astonished to see pale flashes given off on stirring the solidifying ceresin, whilst sparks of 4 cm. long could be drawn by approaching the hand to the surface of the ceresin. The ceresin was quite free from resin. Such a phenomenon has not been previously reported.—G. H. B.

### PATENTS.

*An Improved Anti-Corrosive Lubricant and Lubricating Vapour for Carbon Disulphide and other Vapour Motors.* D. S. Hawke, Cernees. From E. L. Brady, New York, U.S.A. Eng. Pat. 5974, April 8, 1889. 4d.

FIVE quarts of a weak solution of saponin (e.g., 1 oz. to 5 quarts of water) is mixed with 13 quarts of "paraffin or other light mineral oil," and the product injected into the boiler of any engine using the vapour of such a liquid as carbon bisulphide as its motive power. On condensing the exhaust vapour the lubricant is recovered and may be returned to the boiler. The lubricant is said to accompany the vapour through the engine and protect the working parts.—B. B.

*An Improved Manufacture of a Compound of Vinegar and Oil Applicable for Various Purposes.* H. Noerdlinger, Stuttgart, Germany. Eng. Pat. 9564, June 8, 1889. 4d.

A CLEAR and homogeneous mixture of oil and vinegar may be made by adding to an emulsion of the two a soluble salt, such as common salt, which removes the water, leaving a mixture of acetic acid and oil. If acetic acid be used instead of vinegar, no salt is required. An incidental advantage claimed is the purification of the oil. The product is designed for medicinal or culinary purposes.—B. B.

*Improvements in the Manufacture of Lubricating Grease and in the Apparatus Employed therefor.* P. Plisson, Paris, France. Eng. Pat. 1659, January 30, 1890. 8d.

A MIXTURE composed of 2—10 per cent. of some alkali or alkaline earth, 5—60 per cent. of a vegetable oil, and 25—90 per cent. of a mineral oil, is made by placing the saponifiable oil in a steam-jacketed vat, adding the alkaline substance, and incorporating by the aid of a stirring arrangement consisting of a vertical shaft carrying a frame, one of the vertical members of which is free to rotate and bears blades for stirring the mass, while to another are attached scrapers which fit closely to the wall and bottom of the vat, and clear them from adhering material. The whole of this contrivance can be lifted bodily from the vat for cleaning or the removal of its contents. The manufactured product is designed as a lubricant where heavy pressures and high temperatures exist.—B. B.

### XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

#### PATENTS.

*Improvements in and in the Manufacture of a Preparation or Substance applicable as a Substitute for India-rubber, and for Waterproofing or Dressing Cloths, Sheetings, and other Articles; also for other Purposes.* S. Kenyon, Warrington. Eng. Pat. 4179, March 9, 1889. 4d.

Oxidised linseed oil is incorporated, by the aid of heat, with the distillate or "foots" produced in the manufacture of varnish from gums or gum resins, or with pine oil, resin oil, or resin; and the mixture is soluble in oil, turpentine, bisulphide of carbon, mineral spirit, or any of the ordinary solvents for india-rubber.—E. G. C.

*An Improvement in the Manufacture of Coloured Sealing Wax.* J. Fremont, London. Eng. Pat. 5349, March 28, 1889. 4d.

INSTEAD of using vermilion or ultramarine, the inventor dyes the barytes or other pulverulent body added to the wax, with aniline colours.—E. G. C.

*An Improved Material for Making Whitewash, Colour-wash, and Water-Colour Paints.* J. J. Carr, Scarborough. Eng. Pat. 13,792, September 2, 1889. 4d.

A COMPOSITION of whiting and other suitable white substances, colours, and binding or glutinous materials, dried and ground to powder.—E. G. C.

*Improvements in or relating to the Manufacture of Vulcanised Plastic Compounds.* A. J. Boulton, London. From W. Kiel, Butler, New Jersey, U.S.A. Eng. Pat. 15,826, October 8, 1889. 6d.

THIS specification, in which there are 13 claims, refers to the production of a hard substance (suitable for use in place of hard rubber, whalebone, ivory, and the like), by vulcanising wood, sulphur, oil, and crude rubber, the mixture thus obtained being reduced to powder and combined with sulphur, oil, beeswax, and crude rubber. (See this Journal, 1889, 204.)—E. G. C.

*An Improved Adhesive Solution.* J. Saunders, E. Kerry, and E. C. Kerry, Highgate. Eng. Pat. 16,673, October 22, 1889. 4d.

A MIXTURE of gutta-percha tissue ( $1\frac{1}{2}$  part), carbon bisulphide ( $1\frac{1}{2}$  part), and methylated ether (1 part).—E. G. C.

*Improvements relating to the Manufacture of White Lead.* H. H. Lake, London. From J. B. Tibbits, Hoosae, U.S.A. Eng. Pat. 18,076, November 12, 1889. 6d.

ACCORDING to this invention, a lead electrode is electrically dissolved in an electrolyte containing free or nascent carbon dioxide, the lead compound formed by electrolytic action being precipitated to form hydrated carbonate of lead, or pure white lead, which is removed, washed, and dried.

—E. G. C.

*Process and Apparatus for the Manufacture of Linoleum Cloth.* D. N. Melvin, Richmond, U.S.A. Eng. Pat. 18,749, November 22, 1889. 8d.

SHAPES of differently coloured linoleum composition are cut from sheets and placed on wooden blocks according to the desired pattern. The shapes are held in position by a number of pins or thin metal strips. The blocks with the shapes in position are inverted and placed on a canvas

backing laying on a heated table. Pressure is applied to the block, causing the shapes to adhere to the canvas. The block is then removed and the shapes are made to form a continuous sheet by further pressure, a hot plate being placed on the surface. A drawing of the blocks and press used accompanies the specification.—E. J. B.

*Improved Blacking Mixture for Use on Heels, Shanks, and Edges of Boots and Shoes.* A. J. Boulton, London. From J. G. Drew, Lynn, Mass., U.S.A. Eng. Pat. 20,754, December 24, 1889. 4d.

A MIXTURE of shellac, water, borax, oil of sassafras, ammonia, and colouring matter (aniline black).—E. G. C.

### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

*Chemistry of Tannic Acids.* C. Etli. Monatsh. 10, 647—664, and 805.

THE results of previous investigations have shown that the tannic acid  $C_{17}H_{16}O_9$  obtained from *Quercus Robur L.*, and that obtained from *Quercus pubescens W.* occur in the oak-bark not only in the form of the tannic acid but also as anhydride; it was also found that the tannic acids which are almost insoluble in water do not occur in combination with a sugar, and are not therefore glucosides; their basis is not tannin but a substance isomeric therewith, namely, a ketone acid (gallylgallie acid) of the constitution—

formed from two molecules of gallic acid with elimination of one molecule of water.

In this paper the author gives an account of experiments, which show that the tannic acid  $C_{16}H_{14}O_9$  is a derivative of the ketone acid referred to above; as this tannic acid closely resembles the acids previously investigated both in physical and chemical properties, it follows that they also are derivatives of the same ketone acid.

The greater part of the sparingly soluble ketone tannic acids occurs in the plant in combination with a metallic base, probably magnesium, and as these salts are very readily soluble in water they can be easily and completely extracted. After concentrating the aqueous extract and acidifying with hydrochloric acid the tannic acid is precipitated in an insoluble condition, and can be washed free from hydrochloric acid and then purified by extracting with alcohol or ether. In this way the tannic acids can be easily obtained in a pure condition; the most suitable source of these acids are the commercial extracts which are obtained from the bark and wood of various trees and largely used in tanning.

The author has isolated the following tannic acids by the method described above. An acid of the composition  $C_{16}H_{14}O_9$  from the extract obtained by the "Oak-Extract Company" in Slavonia from the wood of the stalk-oak. An acid of the composition  $C_{18}H_{18}O_9$  from the oak-bark used in a tannery at Pesth. An acid  $C_{20}H_{20}O_9$  obtained from the bark of the copper-beech in the neighbourhood of Salzburg. An acid of the composition  $C_{22}H_{22}O_9$  from the hop cones obtained from Saaz.

All these tannic acids have a different colour, varying from brownish-red to bright red; those obtained from the stalk-oak and holm-oak give in dilute alcoholic solution a deep blue, the others, however, a green colouration with ferric chloride. It seems that all the tannic acids obtained from the oak are simply different derivatives of the same ketone tannic acid.

The tannic acid of the composition  $C_{16}H_{14}O_9$ , which occurs in the Slavonian stalk-oak (see above) is best isolated as follows:—The commercial extract, which contains, besides other substances, principally ellagic acid and the tannic acid, is treated with water, the insoluble matter allowed to

settle, and the filtered solution gradually mixed with concentrated hydrochloric acid as long as a red precipitate is produced (excess of acid should not be used). After standing for several days the supernatant liquid is siphoned off, the precipitate collected on a filter, washed with water till free from hydrochloric acid and dried. The dry substance is then treated with 95 per cent. alcohol, the filtered solution mixed with  $1\frac{1}{2}$  volumes of water, again filtered from resinous substances and evaporated to dryness; if the residue thus obtained is completely soluble in 40–45 per cent. (by vol.) alcohol it may be considered to be pure, if not it is redissolved in alcohol of this strength, and the filtered solution evaporated to dryness.

The liquid siphoned from the crude tannic acid contains the whole of the ellagic acid and larger or smaller quantities of tannic acid. It is first evaporated to a small volume, whereon the ellagic acid is converted into insoluble ellagic acid. After adding water the black precipitate is filtered off, washed with water, dried, and extracted with 45 per cent. alcohol. The filtered extract leaves on evaporation the tannic acid,  $C_{16}H_{14}O_9$ , mixed with a small quantity of another tannic acid; the latter can, however, be dissolved out by washing with a large quantity of water.

The tannic acid,  $C_{16}H_{14}O_9$ , is a brownish-red amorphous compound; under the microscope it is seen to consist of small spherical nodules, which are all so much alike that the presence of impurities can be easily detected. It is almost insoluble in water and ether, but very readily soluble in alcohol and acetone. Its solution in dilute alcohol has an acid reaction, gives a precipitate with lead acetate, and a dark blue colouration with ferric chloride. The formation of the phenylhydrazine-derivative,  $C_{22}H_{20}N_2O_8$ , and the oxime,  $C_{16}H_{13}NO_9$ , proves that the acid contains a ketone group.

When the acid is heated with dilute sulphuric acid at  $120^\circ$ – $130^\circ$ , it gives gallic acid (m.p.  $238^\circ$ – $240^\circ$ ), and a large quantity of insoluble anhydro-derivatives. It forms a soluble neutral salt, and several very sparingly soluble basic salts with magnesia. When heated alone at  $130^\circ$ – $135^\circ$ , or at  $100^\circ$  with water, in sealed tubes, or when boiled with hydrochloric or dilute sulphuric acid, it yields various very stable anhydrides, a property which is especially characteristic of the ketone tannic acids, and serves to distinguish them from tannin. When the acid is boiled with dilute (1:10) sulphuric acid, for example, as long as a red precipitate is produced it is converted into an acid anhydride,  $C_{32}H_{24}O_{16}$ , according to the equation—

When heated at  $120^\circ$ – $130^\circ$ , under the same conditions, it gives two anhydrides. The one is soluble in 96 per cent. alcohol, and is formed according to the equation—

The other is insoluble in 96 per cent. alcohol, and no longer contains a carboxyl group, its formation being expressed thus:—

These experiments show that the tannic acid contains four hydroxyl groups; its behaviour with hydriodic acid and with hydrochloric acid shows that it contains two methoxy groups. The acid,  $C_{16}H_{14}O_9$ , is therefore a dimethyl derivative of a ketone acid of the constitution—

but the position of the two methoxy groups has not yet been determined.—P. S. K.

*The Testing of Glue.* R. Kissling. Chem Zeit. 13, 1667.

THE author describes a simple apparatus for measuring the tensile strength of glue. It consists of two solid cylinders of nickel-plated iron, with one end of each made smooth whilst the other end has a hole to receive a hook for support. One part of glue with two parts of water are warmed together on a water-bath, in which the metal cylinders are also heated. The solution is then placed between the smooth ends of the cylinders, which are squeezed together and left overnight in an upright position between suitable wooden supports, and surmounted with a 5-kilo. weight to keep them pressed together. The glued cylinders are then hooked on to a lever carrying a scale pan, to which weights are added, until the cylinders part at the glued joint. The process and apparatus resembles that employed in testing the strength of cement. The results of a number of tests are given, from which it is seen that the price of the glue bears no relation to its tensile strength.—G. H. B.

## XV.—AGRICULTURE, MANURES, Etc.

*Bulletins of the Kentucky Agricultural Experiment Station.* Lexington, Kentucky, U.S.A. Nos. 15, 16, 17, 18, 20, and 21.

No. 15. *Wheat Experiments* (1888).—Of 24 varieties sown in October, nine were killed by the winter, viz., Golden Drop, Squarehead, Hunter's White, Browick Red, four Algerian varieties, and Genoese. Diehl Mediterranean, Hicks, Californian, Red Sea, Fulcaster, Velvet Chaff, and Extra Early Oakley gave good results. The latter has yielded on an average of three years 27.9 bushels per acre. Velvet Chaff gave 30 bushels and was the hardiest.

Experiments with wider drills (14 in. apart) to test the effect of twice cultivating between the drills, showed no improvement over the uncultivated plots. Various manurial experiments showed the land to be in too good condition to benefit by dressings.

No. 16. *Potato Experiments*.—The season was unfavourable for potatoes, and the results of comparison of different varieties are vitiated by this circumstance. But experiments on the best sets for planting confirmed unmistakably the conclusions of a previous year, and those drawn from similar experiments at the Maryland Agricultural Station. These are that large potatoes planted whole produce the largest crops, and that next follow in order average whole potatoes, small whole potatoes, large potatoes cut to two eyes, small potatoes cut to two eyes, single eye on good sized piece, single eye on small piece. If the season and soil be bad, it may not pay to use large potatoes for seed, but with a good soil and fair average season it certainly does. For example, in 1886, large whole potatoes gave value of crop less cost of seed 73.80 dollars per acre; cut to two eyes, value of crop less cost of seed 54.30 dollars per acre.

Potash manures alone gave greatly increased crops on the potato field and were by far the most profitable. This result, of course, applies to the particular field—a blue-grass soil on crystalline limestone of Lower Silurian age, cold and backward, with clay subsoil, cropped since (and perhaps before) 1860 chiefly with cereal and a few hemp crops.

"London Purple" sprayed twice over the field at intervals of a week, was found very effectual against the potato beetle.

No. 17. *Maize Experiments*.—The manurial experiments (made on Ville's principle of comparing a complete manure with no manure, and with potash, nitrogen, and phosphoric acid omitted in turn) showed conclusively the value of potash salts as a manure for maize on this soil, the addition of 60 lb. of potassium sulphate per acre to the hillocks only, raising the crop from 31.6 bushels to 63.7 bushels per acre, and of fodder from 3,450 lb. to 6,420 lb. 100 lb. of potassium sulphate gave still better results, not improved by additions of superphosphate or ammonium salts. The improvement was as great in quality as in

quantity. The results of similar experiments on hemp, tobacco and potatoes, and indications obtained with wheat, point to the advantage of using potash generally on similar well-cropped soils of this region. 60 lb. of copperas per acre mixed with earth or with a complete fertiliser produced no increase, or a diminution of crop, though the leaves were for a time of a darker colour.

Tobacco stems, a waste product, gave very promising results as a manure for maize, probably by reason of the contained potash.

No. 18. *Hemp Experiments*.—Potash salts and ammonium sulphate gave the best results with this crop on the well worn land of the station, which was very unfit for hemp cultivation without manure. *Apple orchard*.—Spraying when the apples are about the size of peas with London Purple (1 oz. to 10 gallons water) has been found most effectual against the ravages of the codlin moth.

No. 20 and No. 14. *Commercial Fertilisers*.—Contain an explanation of the principles of manuring, tables giving analyses and valuations of many current samples of bone manures and mixed manures, and reprints of the Kentucky State Acts regulating the sale of fertilisers.

No. 21. *Wheat Experiments* (1889).—Canadian Finley and Hunter's White varieties gave the best looking grain; German Emperor and Egyptian the largest yields, 30 bushels per acre. Diehl Mediterranean, Hicks, and Extra Early Oakley did not do so well as in the preceding year. The manuring experiments showed that little manuring is needed for wheat on this soil, although, taking three years' results, some effect from the fertilisers is shown, especially from those containing potash. Much damage was caused in 1889 by the grain louse (*Siphonophora avenae*), a species of "green fly," the life history of which is detailed in the bulletin.

The following notice, printed with each bulletin, is worth quoting: "It is desired that every farmer in the State shall receive these bulletins, and become interested in the work of the station. Persons already receiving them would confer a favour by sending in the names of any others they know who are likely to be interested in them. The bulletins of the State will be mailed to any citizen in Kentucky who sends his name and address for that purpose."—J. M. H. M.

*Superphosphate Gypsum*. W. Cohn. Chem. Zeit. **13**, 1671.

OBJECTION has been raised to a statement made by the author in an article on the manufacture of artificial manure (this Journal, 1890, 201), apparently to the effect that superphosphate gypsum is not of greatly more value to the farmer than ordinary gypsum as a means for preventing the escape of ammonia generated in farmyard manure. The author justifies his remarks by reference to the careful experiments of König on this subject, and explains the position he has taken up by showing that the production of superphosphate gypsum is confined to a very few factories, and any advantage derived locally by its use becomes quickly neutralised by cost of transport, whilst the general distribution of gypsum factories causes that substance to be available at a cheap rate in all places.—G. H. B.

*Contribution to the Question of Manuring on the Basis of Soil Analysis*. R. W. Bauer. Chem. Zeit. **13**, 1705.

IN relation to a discussion on the subject of manures, the author draws attention to the advisability of ascertaining by analysis in what respect a soil may be deficient before manuring it with substances in which it may be rich. Thus he found a soil rich in nitrogen but very poor in phosphoric acid, magnesia, and sulphuric acid, and he shows by a tabular statement of the mineral matters present in various cereals that the requisite mineral substances, as well as nitrogen, must all be present in appreciable quantities and available to the plant from the soil.—G. H. B.

*Constitution of Bone Meal*. J. Stocklasa. Chem. Zeit. **14**, 1—2, 21 and 32—33.

See under XXIII., page 420.

*Superphosphate Gypsum and Gypsum Phosphate*. T. Meyer. Chem. Zeit. **14**, 2.

SUPERPHOSPHATE gypsum and gypsum phosphate are both by-products of the manufacture of phosphoric acid from natural phosphates. The former is the substance obtained by drying the residue from the phosphoric acid, after this has been liberated by sulphuric acid. It is valuable from the considerable amount of soluble phosphoric acid it contains. Gypsum phosphate, on the other hand, is the waste product obtained when the precipitate is washed out before being dried: it contains about 3·5 to 4 per cent. of phosphoric acid ( $P_2O_5$ ), most of which is insoluble. Being produced by the action of sulphuric acid on very finely powdered phosphate suspended in water, it is obtained in an extremely finely-divided state and is, therefore, well adapted for the absorption of gases. It will, moreover, absorb about 15 per cent. of moisture (beyond the amount required for the formation of hydrate) without forming lumps. It forms an excellent nitrogen preservative for farmyard manure.—N. H. J. M.

#### PATENT.

*Improved Machine for Disintegrating and Pulverising Hay, Straw, and the like*. C. I. Olsen and H. P. Kjoller, Copenhagen, Denmark. Eng. Pat. 19,689, December 7, 1889. 6d.

INSTEAD of cutting hay in the ordinary way the inventors tear it into a fibrous mass, thereby loosening the outer silicious coating and rendering the nutritive portion more easy of digestion. Knives of a peculiar construction are used.

—E. J. B.

## XVI.—SUGAR, STARCH, GUM, Etc.

*Arabinon, the Saccharon of Arabinose*. C. O'Sullivan. J. Chem. Soc. **57**, 59—63.

THIS body was noticed under the name of  $\alpha$ -arabinose in a previous communication of the author (J. Chem. Soc. **45**, 55). It was prepared from the sugars obtained by the limited action of sulphuric acid on geddie acid (a body to be described in a future communication). The sugar syrups thus obtained were fractionally precipitated by ether until the optical activity of the most insoluble fractions rose to nearly  $[\alpha]_D^{20} = 190$ , and further fractionation did not yield precipitates materially differing from one another.

The purified syrup has an optical activity  $[\alpha]_D^{20} = 202$ , a reducing power of  $K = 58$ , the specific gravity of a solution containing 10 grms. in 100 cc. is 1·0395, and it has a sweet taste.

It appears to be arabinon, the saccharon of arabinose; this is borne out by the fact that it yields arabinose on hydrolysis, 104·9 parts arabinose being obtained from 100 parts of the new body. The equation—

requires a yield of 106·3 parts arabinose. The molecular weight as determined by Raoult's method was found to be 239·2, that of  $C_{10}H_{18}O_9$  being 282, and its analysis gave 42·46 per cent. of carbon and 6·55 per cent. of hydrogen, 42·58 per cent. of carbon and 6·38 per cent. of hydrogen being the theoretical numbers.—A. L. S.

*The Application of the Electrical Conductivity for the Determination of the Ash in Raw Sugar.* A. Fock. Zeits. d. Vereins f. Rübenzucker Industrie, 1889, 710.

This is a critical examination of Reichert's work on the subject, together with a description of the apparatus employed and of the reliability of the constants needed for the determination according to Reichert's method (Zeits. Anal. Chem. 28, 1, and this Journal, 1889, 994). Three sources of error in the determination of the electrical conductivity are pointed out, viz.: (1), the method of preparation of the solution; (2), the measurement of the temperature; (3), the inefficiency of the measuring apparatus. These items introduce an error of 0.4 to 0.5 per cent., but are not sufficiently great to interfere with the accuracy required of the method. The main point to settle, and one which is not supported by enough experimental data in Reichert's work, is whether his constant *b*, the consistency of a pure sugar solution, is a constant quantity, i.e., whether the electrical conductivity of such a solution is really equal to nil, and if not, what its value is. And, further, whether the electrical conductivity is independent of the degree of dilution of the solution. Experiments by the author decide the first point in the affirmative. As regards the second, it is shown that the values for *b* vary considerably with the degree of concentration of the solution, and that the most constant and maximum values are obtained with 1/10 and 1/20 normal solutions (a normal solution contains 26.048 grms. of sugar in 100 cc. of water). The value of *b* also increases with the percentage of ash in the sugar. Since the reliability of the method depends upon the constancy of this value *b*, it appears that the extended applicability of the method pointed out by Reichert is out of the question, but for sugar containing a small percentage of ash the error does not exceed 0.1 per cent., and this is sufficiently accurate. The objections to the method for practical use are pointed out as consisting in the careful manipulation required, the constant attention necessary, and the great difficulty of keeping the solution tested at a constant temperature, without which the results are of little value, since the electrical conductivity varies greatly with the temperature.—C. A. K.

#### PATENTS.

*Improvements in Preparations of Cane and Beet Sugar.* A. G. Salamon, London. Eng. Pat. 3526, February 27, 1889. 6d.

THE invention consists in the production of mixtures of saccharin (benzyl sulphonic imide) with cane or beet sugars, the resulting products being much sweeter, weight for weight, than either cane or beet sugar alone. By the addition of  $7\frac{1}{4}$  lb. of pure saccharin to 1 ton of sugar, the sweetening power of the sugar is doubled weight for weight. A claim is also made for decreased tendency to fermentation in the saccharinated sugar.—A. J. K.

*Improvements in and connected with Apparatus for Evaporating and Concentrating Saccharin or other Solutions.* J. G. Chapman, London. Eng. Pat. 8596, May 23, 1889. 8d.

IN order to facilitate the discharge of the "masse euite," the size of the discharge valve is greatly increased. To effect this the bottom of the pan is made moveable, so that the area of the discharge outlet is equal to the section of the vacuum pan at its base.—A. J. K.

*Improved Process for obtaining the Entire Quantity of Crystallisable Sugar contained in Sugar Mass.* C. Steffen, Vienna, Austria. Eng. Pat. 20,515, December 20, 1889. 4d.

THE methods hitherto known and applied for setting free sugar masses from thin syrup are limited to the separation of the syrup from the crystals. The syrup is afterwards

allowed to cool down until the crystallisable sugar which it still contains separates out. By this method the sugar of the syrup, instead of going to increase the size of the crystals of the "masse euite," is obtained separately in a finely crystalline mass of low commercial value. According to this invention, the whole of the pure "masse euite" is run off into suitable vessels, mixed with molasses of the refinery to a thin homogeneous crystalline pulp. The whole mixture is now submitted to a cooling and stirring process for from 12 to 24 hours.

The entire crystallisable sugar contained in the mother-liquor of the "masse euite" is in this manner won in a marketable form, together with the sugar crystals previously formed in the vacuum pan.—A. J. K.

*Improved Treatment of Sugar Crystals or Grains for Facilitating the Purifying or Washing thereof.* C. D. Abel, London. From Pfeifer and Langen, Cologne, Germany. Eng. Pat. 1282, January 24, 1890. 4d.

IN order to facilitate the washing of the grains of "masse euite" or other granular sugar in cases where the grains are very small and the "masse" is dense, the sugar to be washed is previously treated as follows:—(1.) The "masse" is first heated and then allowed to cool slowly; (2.) The "masse" is subjected to a drying process.

—A. J. K.

#### ERRATUM.

This Journal, 1890, 312, left-hand col., lines 13 and 21 from bottom, also right-hand col., lines 1, 5, 26, and 29, for "Mannosic" read "Mannonic." Right-hand col., line 1, for "Arabinosic" read "Arabinonic."

### XVII.—BREWING, WINES, SPIRITS, Etc.

*The Decomposition of Gelatin by Anaerobic Bacteria.* L. Sclitrenny. Monatsh. 10, 908—917.

THE author dissolved 800 grms. gelatin in 16 litres of water, which was sterilised, and then inoculated with *Bacterium liquefaciens magnus*. The air was then expelled from the vessels holding the solutions by a current of carbon dioxide.

The solution was investigated, one portion after a period of 22, and another after 32 days.

The liquid was distilled from a retort after the addition of oxalic acid. A small quantity of methyl mercaptan was collected, but indol, scatol, and phenol were not detected. The chief portion of the distillate consisted of phenyl propionic acid. The residue in the retort, after precipitation of the oxalic acid, was found to be mainly glycecol, which was separated in the form of the copper salt.

A second experiment was conducted similarly, but in presence of a small quantity of air. In the second experiment, the distillate contained phenyl acetic acid as well as phenyl propionic acid, the former being the larger amount. In both cases a considerable quantity of gelatin peptone was formed.

The author supposes that by the complete decomposition of gelatin in this way, one-half is converted into peptone, and the other into crystalloid substances, of which 2—3 per cent. is phenylamidopropionic acid.

The fermentation products of gelatin differ from those of ordinary albumen, in that no *p*-oxyphenylpropionic acid nor scatol acetic acid are formed, and also by the presence of large quantities of amido acids of the fatty series in the case of the gelatin fermentation.—J. B. C.

*Substances occurring in Raw Spirit.* H. Bornträger. *Zeits. Anal. Chem.* **28**, 670. (Compare this Journal, 1889, 64.)

In continuation of the author's investigations on the reactions of substances occurring in raw spirit, the principal characteristics of normal propyl alcohol and fermentation butyl alcohol are given.

Normal propyl alcohol has a pleasant fruity smell, and boils at 97°; with water, at 87°. Its specific gravity is 0.813, and it is readily soluble in water. It is not extracted from a 33 per cent. alcoholic solution by shaking with chloroform.

Fermentation butyl alcohol has an unpleasant smell, recalling that of fusel oil, and boils at 108°–109°. Its specific gravity is 0.805, and it is only sparingly (1:10) soluble in water. It is extracted from its solution in 33 per cent. alcohol by shaking with water. When dissolved in alcohol and the solution treated with three drops of concentrated hydrochloric acid and 10 drops of aniline, a red colouration is produced, but only in strong solutions.

If raw spirit is diluted to 33 per cent., and then shaken with chloroform, the extract will contain amyl alcohol, acetal, aldehyde, and fermentation butyl alcohol, whilst ethyl alcohol, acetic acid, and tertiary butyl alcohol will remain in the dilute alcoholic solution.—F. S. K.

*The Development and Prospects of the Spirit Manufacture in Hungary.* A. von Asbóth. *Chem. Zeit.* **14**, 65–66 and 127–128.

HUNGARY being a wine-producing country, little attention was paid to the manufacture of spirits until the beginning of this century, when the trade being found profitable grew largely, and soon supplied the home market and began to produce a surplus for export. To meet these altered conditions fiscal changes were made which considerably hampered the industry. In 1862 the number of distilleries and their output declined considerably, and though their burden of taxation was somewhat reduced in 1865, yet the many small distilleries attached to estates and not worked as separate enterprises were unable to compete successfully with the large manufactories. For the relief of the former measures were adopted which resulted in a further rapid growth, until production was again checked by the bounties granted by neighbouring countries, especially Russia and Roumania. But the regulations then in force were successful neither financially nor industrially, as may be gathered from the facts that the tax yielded only 66 kr. per head, while in other European States the return varies from 2.25 fl. to 5 fl. per head, and that the favoured small distilleries adopted wasteful methods of working. The upshot of these difficulties was the imposition in 1888 of an uniform tax on the output of spirit, which was made legal in both Austria and Hungary and had the following provisions: 35 kr. were levied on each litre of alcohol supplied for home consumption, which was reckoned at 1,878,000 hectolitres, and divided among the distilleries in due proportion. If a distillery made more than its allotted share, the surplus was taxed at the rate of 45 kr. per litre. This tax was not levied on spirit exported in other forms, such as liqueurs, nor was it required from spirit for industrial, medicinal, or scientific purposes, a duty of 1½ kr. only being charged. Spirit for export was also made duty-free. For the benefit of the smaller distilleries, a bounty of 3 fl. per hectolitre for those producing 4–7 hectolitres per day; of 4 fl. for those producing 2–4 hectolitres per day, and of 5 fl. for those producing less than 2 hectolitres per day was granted. To encourage export, a bounty of 17½ kr. per hectolitre-degree on untaxed denatured spirit, and 5 kr. on duty-paid spirit was instituted, with the proviso that the total sum thus paid should not exceed one million gulden, to ensure which only half the bounty was paid at the time of export, and the rest at the end of the season. Duty-free spirit is denatured with wood-spirit and pyridine bases; in order to ensure its detection if added to potable liquids, phenolphthalein is also added. An opinion on the effect of these regulations cannot be given until the returns are available.

In conclusion, the author remarks that the Bohm-Fredersdorf and Ulger stills are chiefly used in the larger Hungarian distilleries; that the raw materials employed include maize, potatoes, wheat, rye, sugar-beet, molasses, different kinds of fruit, and refuse from the wine and sugar manufactures. An idea of the size of the industry may be gathered from the fact that there were, in 1887, 65 distilleries which paid a tax of more than 20,000 fl. apiece.—B. B.

*The Quality of Commercial Alcohol.* J. Szilágyi. *Chem. Zeit.* **14**, 66.

SPRIT made on the estates of various Hungarian land-owners (see preceding abstract) was examined for fusel oil by the Röse-Herzfeld method (this Journal, 1888, 871) with the following results:—

Source of the Crude Spirit.	Alcohol.	Fusel Oil.
	Per Cent. by Weight.	Per 100 Parts abs. Alc.
Potatoes .....	89.04	0.3279
	89.71	0.2566
Turnips .....	80.50	0.793
	78.10	0.8178
Maize .....	81.95	0.2068
Maize and potatoes .....	80.74	0.3629
Molasses .....	81.35	0.3745

The percentage of fusel oil increases after long uninterrupted use of any form of continuous still; on cleaning the still used for the production of maize spirit (see table) it fell to 0.1671 per cent. The process of purification commonly adopted consists in diluting the crude spirit to the extent of about 50 per cent. with water, filtering through linden-wood charcoal and rectifying; the portion collected after the first runnings (which are not marketable) is known as "second quality" ("secunda sprit"), the next as "good" or ordinary quality, the next as "fine quality," and the middle fraction as "finest spirits of wine," after which fractions similarly named in reverse order come over, and finally last-runnings and fusel oil. The character of these products may be gathered from the following figures, which were obtained by the examination of those manufactured by a single large firm:—

—	Alcohol.	Fusel Oil.	Remarks.
	Per Cent. by Weight.	Per 100 Parts abs. Alc.	
Second quality	93.4	0.0206	Perceptible aldehyde reaction.
Ordinary do.	93.4	0.0	Trace of aldehyde.
Fine do.	94.6	0.0	.. ..
Spirits of wine	94.6	0.0	.. ..

—B. B.

*The Action of Diastase on Ungelatinised Starch.* C. J. Lintner. *Brauer and Mälzerkalender*, **13**, 83.

THE author has made some experiments to determine the action of diastase at various temperatures on unaltered starch. In each experiment 2 grms. of air-dried starch were treated for four hours with 50 cc. of malt extract. The solution was then diluted to 100 cc. and filtered from unaltered starch. The filtrate was inverted with hydrochloric acid, the glucose formed being determined by Fehling's solution. The following table shows the

percentage of dry starch converted in each case by the diastase :—

Nature of Starch.	Temperature.			
	50° C.	55° C.	60° C.	65° C.
Potato starch.....	0·13	5·03	52·68	90·34
Rice starch .....	6·58	9·68	19·68	31·14
Barley starch .....	12·13	53·30	92·81	96·24
Green malt starch .....	29·70	58·65	92·13	96·26
Cured malt starch .....	13·07	56·02	91·70	93·62
Wheaten starch.....	..	62·23	91·08	94·58

—H. T. P.

*A New System of Brewing.* R. Wahl and M. Henius. Der Braumeister, Chicago, 3, 88.

THE authors describe a new system of brewing, designed by L. Frisch, for the purpose of more completely utilising the starch of raw grain and malt. The raw grain is mixed with water and heated to a temperature of about 115° R. (143·3° C.) in a closed iron boiler. The mixture is then cooled to 55° R. (68·3° C.), ground malt is added, and the whole is stirred up until the conversion into maltose and dextrin is complete. Frisch employs for these operations Hollefreund's apparatus, as used in distilleries. Further, it is possible to produce by means of this apparatus a pale all malt beer. In this case the mash is boiled in vacuo at 65° R. (81·4° C.). A trial mash was made in the experimental brewing station at Chicago, using maize and malt. The ratio of sugars to non-sugars in the raw grain wort was 100:51·7; in the finished wort before pitching, 100:44. The finished beer gave the following results on analysis: Saccharometer reading, 4·15 per cent.; alcohol, 3·48 per cent.; extract, 5·81 per cent.; sugar, 2·17 per cent.; albuminoids, 0·48 per cent.; lactic acid, 0·86 per cent.; ash, 0·17 per cent. The beer and worts were, therefore, of normal composition.—H. T. P.

#### PATENTS.

*Improvements in the Preparation of Malt.* G. Reininghaus, Mainz, Germany. Eng. Pat. 5981, April 8, 1889. 6d.

IN the process of soaking or steeping of the grain (barley) in breweries and brandy distilleries, the grain is usually conveyed to the steeping troughs by means of elevators, carts, spirals, &c. By the present invention the grain is carried through pipes by a current of water.—A. J. K.

*An Improved Process and Apparatus for Testing the Presence of Colouring Matter in Wines.* L. Mathieu and J. Morfaux, Constantine, France. Eng. Pat. 6083, April 9, 1889. 8d.

WHITE ungummed silk is immersed for 12 hours in a bath of one part of nitric acid (63° B.) and nine parts of water; it is subsequently well washed with water. A bunch of silk so treated is then suspended, by means of a ring, from the metal cap of a test tube, filled with the wine to be tested. The immersion in the wine lasts 10 minutes, after which the silk is pressed between the fingers and plunged into a tube containing a solution made up as follows: 450 grms. of neutral acetate of lead in crystals are dissolved in 1,000 grms. of distilled water containing 20 cc. of glacial acetic acid; dilute this solution with 10 times its volume of water. If the wine be unadulterated with colouring matter the silk as above treated turns green, greyish, or bluish, according to the character of the vintage. If any red tint remains it denotes the presence of some of the red coal-tar dyes, or of cochineal, carmine, or orseille.—T. L. B.

*Improvements in the Manufacture of German Yeast.* C. R. Boune, London. Eng. Pat. 6918, April 25, 1889. 4d.

THE patentee considers that the worts obtained in the usual manner do not contain sufficient albuminoid for the proper

growth of the yeast, and he extracts a further quantity from the spent grains remaining after the usual mashing.

The spent grains are placed in a high pressure converter with a little water and a small quantity of acid to prevent "caramelisation," and heated for 3—4 hours under a pressure of about four atmospheres. By this treatment most of the albumen will have become soluble. This may be filtered from the residue and added to the original wort and the yeast grown in the mixture.—A. L. S.

*Improvements in Apparatus for Sterilising Fermented Alcoholic Liquors.* L. A. Einzinger, Worms, Hesse. Eng. Pat. 8343, May 20, 1889. 8d.

THE inventor passes the liquor to be sterilised through three series of tubes, each series being arranged in a water tank. The water in the first tank is kept boiling by injected steam, while the water in the second tank is kept cold by a continuous current of water, the third tank being filled with ice. The alcoholic liquor passing through the tubes is thus first of all heated to the boiling point, which completely sterilises it, then cooled as much as possible by cold water, and lastly, reduced to nearly the freezing point by ice. If beer, or any other liquor containing dissolved carbonic acid, be treated by the apparatus, the tanks should be arranged one above another, so that the gas disengaged by the heating may rise into the cool liquor and be re-absorbed. Drawings of the apparatus accompany the specification.

—A. L. S.

*Improvements in and relating to Distillatory Apparatus.* A. de Kunwald, Paris, France. Eng. Pat. 16,478, October 18, 1889. 8d.

THERE are two claims, the first for an improved method for heating the still by steam, and the second for a valve for regulating the amount of wash passing into the still, according to the amount of spirit distilling off. The steam heater consists of a boiler and a steam jacket to the still, the steam from the boiler being conducted to the jacket by one pipe and the condensed water run back to the boiler by another. The apparatus may be simplified by making the boiler also serve as the steam jacket, the still being mounted over the boiler. The regulating valve consists of a pressure gauge attached to the still, which, by means of levers, controls a valve on the pipe conducting the wash to the still. As the opening by which the vapours escape from the still is of constant size, so, the greater the amount of evaporation, the greater will be the pressure inside the still, and the regulating valve will admit more wash, and *vice versa*. Drawings of the apparatus accompany the specification.—A. L. S.

*Improvements in or relating to Apparatus for Manufacturing Aërated Water Beverages.* J. McEwen, Manchester. Eng. Pat. 20,490, December 20, 1889. 6d.

THE apparatus described herein belongs to that class in which aërated waters can be manufactured "continuously." A is a generator in which the carbonic acid gas is liberated, and conducted by pipe D into the gas-holder B. C is a washing apparatus through which the gas passes on its way to the condensing pump through pipe E. K is a closed cistern, supplied with water through pipe N and valve O. The condensing pump G draws a combined charge of gas and water through the three-way cock F, and delivers it into the condensing vessel H, from whence it is drawn off to the bottling machine. The escape valve V is adjusted so that the excess of water, charged with gas thrown by the pump, over that taken away by the bottling machines, is returned to the tank K, through the contents of which it is distributed by the perforated inverted trays S S S. The weighted relief valve U serves for the automatic return of the charged water to the tank K when the valve V does not take it away from the condensing vessel at a sufficient rate. The apparatus as shown is capable of delivering a "continuous" supply of aërated water.—C. C. H.

(For drawing see top of next page.)

*Improvements in Apparatus for Syringing Aerated Water Beverages.* J. McEwen, Manchester. Eng. Pat. 20,845, December 28, 1889. 6d.

THE improved syringing pump will be understood from the annexed illustration. K is a glass cylinder enclosed in a metallic casing J, in this is a pump plunger X with hollow piston rod. H is the inlet valve of the pump admitting syrup from pipe F. Q, on the outer end of the rod, is the outlet valve. The adjustable screwed tube V, provided with lock-nut W, regulates the stroke of the pump, and hence the quantity of syrup delivered. The bottle is placed as shown, and driven upwards by the treadle B.—C. C. H.

(For drawing see next column.)

*Improvements in or Connected with Sterilising Apparatus.* J. F. H. Gronwald and E. H. C. Oehlmann, Berlin, Germany. Eng. Pat. 206, January 6, 1890. 6d.

See under XVIII. (A.), page 405.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

### (A.)—CHEMISTRY OF FOOD.

*Sulphurous Acid in Preserved Foods.* J. Brand Bayer. Ind. and Gewerbebl. N. F. 1889, 21, 703.

THE limits (in Germany) to the amount of sulphurous acid allowed, are in beer 10 mgr. per litre, and in wine, 20 mgr. per litre. Direct addition of sulphurous acid or its salts to foods for preservative purposes is not allowed. The author has detected in the liquid from a bottle of preserved asparagus, 0.157 per cent. sulphurous acid and 0.195 per cent. sulphuric acid, part of which was probably produced by oxidation of sulphurous acid.—A. L. S.

### PATENTS.

*Further Improvements in the Preparation and Combination of Animal Substances for use as Food.* J. L. Johnston, London. Eng. Pat. 19,009, December 29, 1888. 6d.

THE first portion of this specification deals with the preparation of sterilised pulverised meat. The meat operated upon is chopped or suitably minced and heated in a closed

vessel at a temperature of from 240° to 300° F. from half an hour to two hours. In order to facilitate the reduction of moisture the interior of the vessel is connected with a suitable exhausting apparatus. It is sometimes desirable to admit superheated steam to the interior of the vessel so as to effectually destroy all spores which would lead to subsequent putrefaction, or the interior surfaces may be cleansed by the use of an antiseptic, e.g. bisulphite of lime. The meat is then removed to a drying room, where it is spread on steam-heated shelves and kept at a temperature of 100° to 180° F., after which it is sufficiently dry to be comminuted or pulverised. The second portion of the specification deals with the preparation of non-coagulable albumen. This substance if heated becomes first coagulated; at a temperature of 265° F. it is converted into a deep brown jelly, and if heated up to 330° F. it becomes finally liquid and does not again coagulate. Albumen so prepared, if heated with an equal bulk of meat peptone, solidifies to a jelly. The various substances described above may be mixed in varying proportions in order to produce a suitable food. The third portion of the specification describes the substitution in such foods of the vegetable product "Japanese isinglass" for animal gelatin.—C. C. H.

*Improvements in the Manufacture of Butter.* J. Boyd, Elmhurst, Illinois, U.S.A. Eng. Pat. 10,693, July 2, 1889. 8d.

THE Danish method of securing a good yield of butter from cream by the addition of a small quantity of skim milk which has been soured by heating and allowing to cool is not always certain in its action. The inventor finds this is due to fluctuations of temperature during the cooling, and rectifies the defect by placing the milk and also the cream used in vessels enclosed in a non-conducting casing. The operation is then as follows:—The "starter" of skim milk is prepared by heating to 90° F. and cooling in a vessel as described above for 24 hours; this is rubbed through a hair sieve and added to the cream at a temperature of 65° F. enclosed in a non-conducting coated vessel in the proportion of one pint of "starter" to 100 quarts of cream, allowed to stand 24 hours and then churned. The yield of butter is then found to be good in quality and quantity and uniform.—C. C. H.

*An Improved Infusing Apparatus, chiefly Designed for Use in obtaining Infusions of Coffee or Tea.* E. Ringaud, Paris, France. Eng. Pat. 13,224, August 22, 1889. 8d.

A METALLIC boiler is connected by means of a siphon with an upper receptacle of glass containing the substance to be infused. The boiler is provided with a screw valve, having a side channel for the admission of air. The water being heated is caused to rise up the siphon into the receptacle, producing a vacuum in the boiler. On discontinuing the heating of the boiler, the atmospheric pressure on the liquid in the receptacle causes it to descend, but the valve being now opened equalises the pressure and prevents the liquid saturated with coffee, &c., from descending into the boiler during the time of the infusion. The infusion having been made, the valve is closed and heat again applied to the boiler for a few seconds. The small quantity of water remaining in the boiler is vaporised and carries the air with it. A vacuum is re-established and the liquid is forced out through the siphon, leaving the residue of coffee, &c., the whole aromatic principle having been expressed. The infusion is thus prevented coming in contact with the hot metal and is drawn off by a tap near the bottom. The principal advantage consists in obtaining the infusion without heating anything but the water.—E. S.

*Improvements in the Preparation of Rennet Powder for Use in Cheesemaking.* R. Dendy, Bristol. Eng. Pat. 17,380, November 2, 1889. 4d.

THE vells are finely divided and then macerated in a solution of common salt containing from 12½ to 18 per cent. of salt. After separation of the mucus, &c., a clean extract is

obtained by filtration and a further quantity of salt not exceeding 5 per cent. is added. The rennet precipitated is dried at a temperature under 35° C. and additional salt added according to the desired degree of concentration. The extract from which the ferment has been precipitated may be used as a weak solution of rennet or as a menstruum for the preparation of liquid extract of rennet. The patentee claims that the ferment as prepared above yields a superior cheese to that prepared in the usual way by the aid of acids or certain preservatives.—C. C. H.

*An Improved Method of and Apparatus for Determining the Quantity of Fat in Milk.* L. K. Lindström, Akerby, Sweden. Eng. Pat. 20,859, December 28, 1889. 6d.

THE fat is obtained in the solid state and in this respect the method is an improvement on the older methods, where the fat is obtained in a liquid or semi-liquid state. 10 cc. of milk are measured into a test tube and a similar quantity of hydrochloric acid, either alone or mixed with acetic acid or sulphuric, is added. The mixture having been well shaken is introduced into a narrow cylinder and subjected to a boiling temperature for 15 minutes. The cylinder is then placed horizontally in a centrifugal machine and the machine rotated at a speed of 2,000 to 3,000 revolutions per minute for five minutes, the temperature being kept at 55°–60° C. by a stream of water running through the machine; revolution is continued for another five minutes at a temperature of 10° C. The cylinder is then removed and the fat may be read off by means of a scale and vernier, as it will have deposited itself in a semi-transparent layer with distinct edges. A large number of tests may of course be made at one and the same time. The results agree very well with results obtained by analysis. Drawings of the apparatus are given in the specification.—T. L. B.

*Improvements in or connected with Sterilising Apparatus.* J. F. H. Gronwald and E. H. C. Oehlmann, Berlin, Germany. Eng. Pat. 206, January 6, 1890. 6d.

THE invention relates to apparatus for sterilising milk and other liquids in bottles, the liquid contained in which can be sterilised under steam pressure, thereby preventing the boiling over of the liquid, and the bottle, immediately after the operation, can be closed inside the apparatus, without coming in contact with the outer atmosphere. A heating vessel contains a stand, with receivers for the bottles. Through the bottom of the vessel and bottle stand a rod, guided in a stuffing-box, passes, and carries at the top a press-plate, while at the bottom it is connected to a lever. The bottles, provided preferably with Fritznor's stoppers placed loosely upon the necks, are placed upon the receivers in such a manner that the press-plate in descending closes all the bottles simultaneously. The vessel being filled with water, the cover is bolted on, and heated by steam. The milk is gradually raised to boiling point; the steam meanwhile filling the interior of the apparatus, not only sterilises the air, but, by its pressure, prevents the rising and boiling over of the milk, and allows the bottles to be almost completely filled, instead of partially, as in the ordinary method. Sterilisation having been completed, the pressure-plate is drawn down, and all the bottles closed simultaneously. "As a mixture of air and steam was contained in the apparatus during boiling, the refrigeration of the milk in the bottles will not produce any appreciable vacuum to affect the contents injuriously."—E. S.

#### (B.)—SANITARY CHEMISTRY.

*Experiments on the Movements of Sewer Air at Wimbledon.* 1888. W. S. Crimp. Proceedings of the Institution of Civil Engineers, 97. Part 3.

THIS paper gives an account of a long series of experiments made by the author to determine exactly the causes which influence the movements of air in a sewer. It has generally been supposed that the direction of such movements

depended upon differences of level or differences of temperature. These suppositions are, however, shown to be quite erroneous, and the author conclusively establishes that in many instances the movements are in a direction contrary to that in which it should be, according to the conditions of one or other of these circumstances. Further, the air currents may be downward or upward, and entirely depends upon the direction and effects of the wind. His conclusions are, "that the wind is the only agent affecting sewer ventilation which need be recognised, and its proper utilisation is a simple and inexpensive matter."—C. C. H.

#### PATENTS.

*Improvements in the Treatment of Sewage.* T. Donnithorne, Mill Hill. Eng. Pat. 11,663, August 13, 1888. 11d.

This specification will not admit of proper abstraction. It deals with the transportation of the sewage and a combination of processes for the treatment of the latter, for details of which the original must be consulted.—C. C. H.

*Improvements relating to the Treatment of Sewage, and to Apparatus therefor.* W. Clark and W. A. Clark, Charlton, and K. Ginnam and W. Ginnam, Plumstead. Eng. Pat. 14,108, October 1, 1888. 1s. 1d.

The sewage is diverted into channels from the main sewer, and each of such channels communicates with a closed filter. The filter is cylindrical; the walls of the cylinder are formed of sheets of gauze or other fabric containing between them a bed of filtering material. The interior of the cylinder is provided with a revolving scraper or "flyer," like a centrifugal pump, and this serves the double purpose of imparting centrifugal force to the water, and hence an urged filtration, and also scrapes the interior of the filter clean, forcing the solid matter through a door or valve in the bottom of the filter. The liquid from the filter is conducted away by channels beneath each row of filters, and the solid matter from the filters is conveyed away by an endless band.

—C. C. H.

*Improvements connected with Apparatus employed for Softening or for Clarifying Water.* A. K. Brown, London. Eng. Pat. 14,761, October 13, 1888. 8d.

This invention describes modifications in the arrangements of the settling plates in the well-known "subsidence" form of apparatus used in the process of water softening. The first modification described and illustrated shows the corrugated plates employed with the line of corrugations placed alternately vertically and horizontally. (2.) Plain flat sheets inclined may be set in a tank to fulfil similar functions. (3.) Plain sheets may be disposed in a tank so that one of their ends can be moved or shaken in order to loosen the deposit which settles upon them.—C. C. H.

*Improvements relating to the Filtration of Water and to Apparatus therefor.* G. D. Gerson, Hamburg, Germany. Eng. Pat. 15,330, October 24, 1888. 8d.

The filtering apparatus herein described is applicable to the filtration of water for technical purposes merely by the removal of the suspended matter and, in addition, its further purification for drinking purposes. Cylindrical vessels are suspended in pairs on trunnions and suitably connected; these are packed with sponge compressed between perforated plates operated by a screw external to the cylinder. The upper portion of the filter is packed with pumice stone, and both this and the compressed sponge may be saturated with an antiseptic insoluble salt, such as tannate of iron. If the water is to be used for domestic purposes after treatment in the filters above described, it is passed through a similar pan packed with treated pumice stone.—C. C. H.

*Improved Apparatus for Screening and Extracting the Suspended Matter from Sewage or other Liquid.* C. F. Gower, Ipswich. Eng. Pat. 1144, January 22, 1889. 8d.

THE improved screening apparatus is set in a chamber through which the sewage passes. It consists of a continuous web of wirework passing over two rollers, one set in the screening chamber and below the level of its bottom, the other some little distance above the top of the walls of the chamber. On the exterior surface of the web of wirework strips of iron forming shelves or pockets are secured. Rotation of the upper drum secures the movement of the continuous screen, bringing with it the matter separated. This drops off into a suitable receptacle, or is removed by revolving brushes to which an endwise motion is also given.

—C. C. H.

*An Improved Method for Softening and Clarifying Water and Apparatus therefor.* L. Archbutt and R. M. Deeley, Derby. Eng. Pat. 1791, February 1, 1889. 8d.

WHEN water is softened by Clark's process, the precipitate, formed takes several hours to settle. If, however, when the reagents have been added, the settled precipitate from a former operation be thoroughly mixed with the water under treatment, the settlement is much more rapid, indeed half an hour suffices to obtain water sufficiently free from solid matter for most purposes. The apparatus described consists of a tank large enough for the precipitation, a reagent vessel from which the precipitating agent is added, and a well inside the precipitating tank provided with a trajectory so as to secure a thorough circulation and consequent mixture of the water and the reagents used. A series of perforated pipes along the bottom of the tank are provided, so that by means of steam or air the mud from a previous operation can be mixed with the freshly treated water.—C. C. H.

*Improvements relating to the Treatment of Feculent Matter, and to Apparatus therefor.* H. H. Lake, London. From J. Hirschfeld, Philadelphia, U.S.A. Eng. Pat. 6528, April 16, 1889. 8d.

IN specification of Eng. Pat. 17,793 of 1888, the present patentee described a form of closet or receiver for feculent matter similar to Moule's earth closet. The present specification describes various improvements effected in the arrangements of the parts of the apparatus referred to, such improvements being covered by 18 claims.—C. C. H.

*Improvements in and relating to Means for Purifying Water.* J. Davis, Allegheny, Pennsylvania, U.S.A. Eng. Pat. 7630, May 7, 1889. 8d.

THE patentee describes at considerable length an improved apparatus for the treatment and purification of water. Generally described this consists of an oblong closed vessel with convex sides and a dished top and bottom containing filtering material resting on a perforated false bottom. Filtering materials similar to those usually employed rest on this perforated bottom. Prior to entering the filter the incoming water drives a turbine which works air pumps for the purpose of aerating the water, and also actuates a series of vertical agitating shafts provided with blades which effectually stir up the filtering beds so as to secure "a free passage of the water through it." The incoming water is also mixed in proper proportions with a suitable reagent, e.g., alum, so as to "coagulate the animalcular and other impurities."—C. C. H.

#### (C)—DISINFECTANTS.

#### PATENTS.

*Self-acting Apparatus for the Periodic Dispersion of Disinfectants, Antiseptics, or other Substances of a like Nature in the Form of Jets and Sprays.* A. R. Upward, London. Eng. Pat. 2248, February 8, 1889. 8d.

IN this apparatus a jet of water is utilised to produce an air blast which actuates the sprays or jets. A jet of water of

high pressure issuing from a nozzle of small aperture flows into a passage somewhat larger than the nozzle and immediately opposite it, and in so doing draws air in with it, and both enter an air-tight vessel in which is a float actuating a waste valve so adjusted as to provide an air-tight space in the upper part of the vessel for the compressed air. A pipe communicating with the air space supplies the spray with the necessary blast. To obtain an intermittent action of the sprays, the above vessel is combined with a tap controlling the supply of water, and consists of a counterbalanced lever and bucket fitted to the tap, the bucket lever periodically opening and closing the valve by the variation of its weight by being first filled from a tipping cup, supplied by an independent minute and accurately adjusted drip from the main, and then afterwards emptied by a minute aperture at the bottom of the bucket. "Where the spray is only occasionally required, the valve connecting the nozzle with the water supply is so connected with the door of the place in which the spray jet is placed, that it is opened by the opening of the door. The valve is fitted with a dash-pot, which only allows the valve to close slowly."—E. S.

*A New Disinfectant and Deodoriser.* A. J. Shitton, Reading. Eng. Pat. 2537, February 13, 1889. 4d.

THE new disinfectant consists of iodine dissolved in an alkaline iodide, *e.g.*, 1 oz. of iodine, 2 oz. of potassium iodide, 1 gallon of water.—C. C. H.

## XIX.—PAPER, PASTEBOARD, Etc.

*Tobacco Juice as a Reagent for Lignin.* A. Hbl. Chem. Zeit. 14, 67.

See under XXIII., page 418.

*On the Physical Changes of Paper when Stored.* W. Herzberg. Mittheil. der Kön. techn. Versuchsanstalten, 1890, 50—52.

THE author has examined at different times three kinds of paper which were stored away for the last three years. These papers had the following composition:—

- I. Made of pure rags.
- II. Made of 75 per cent. rags and 25 per cent. sulphite-cellulose.
- III. Made of 40 per cent. rags and 60 per cent. sulphite-cellulose.

The object of the examinations was to find out whether the papers had changed as regards tearing length and elongation at fracture. The result in all cases was that the papers had not changed during the time mentioned. The author points out that, even in the most carefully manufactured papers, no sheet is of an entirely uniform firmness. Therefore slight differences in the tearing length and elongation at fracture are by no means sufficient for conclusions to be drawn on variations in these respects. It has been stated (compare this Journal, 1888, 689) that the firmness of paper sized with resin increases by storage, and that the tensile strength of paper prepared with the addition of sulphite-cellulose is diminished by storage, whilst paper made from rags does not suffer in this respect. The author does not deny the possible correctness of these statements, but thinks they are not proved conclusively and no prejudice based upon the few existing experiments should be raised against a certain class of raw materials. Moreover, the very important influence which moisture has upon the firmness of paper has in many instances been overlooked, and the author feels sure that no comparative tests for firmness are conclusive, unless made under equal or similar conditions of atmospheric moisture.—H. S.

## PATENTS.

*An Improved Portable Machine for Testing the Strength of Paper.* W. Sinclair, Glasgow. Eng. Pat. 3161 February 22, 1889. 8d.

THIS machine is shown in front and side elevation in Figs. 1 and 2. It consists of two bars A, to the ends of which are

fixed two cross-pieces B and B<sub>1</sub>, forming a rectangular frame. Sliding freely on the rods A are two other cross-pieces C and D. C is rigidly connected with the bolt E which passes loosely through the cross-piece D. C and D are kept apart by the spiral springs G surrounding the rods A, and D is kept from B<sub>1</sub> by the stop H fixed on the bolt E. The paper to be tested is clamped to B and D as shown by the dotted line O in Fig. 2. By moving the thumb-screw F the cross-piece C is brought towards B<sub>1</sub>. At the same time pressure is communicated through the springs G to the cross-piece D and therefore to the strip of paper, until the latter breaks. The pressure required to break the paper is recorded by the pointer K on the dial I. The dial is fixed to a box I which is itself attached to the cross-piece D by the piece of metal D<sub>1</sub>. The rod C<sub>1</sub> is fastened to the cross-piece C. As the latter descends, the rod C<sub>1</sub>, which is furnished with a rack, actuates a small pinion connected with the pointer K and causes the latter to move over the dial.—E. J. B.

*Improvements in the Preparation of Tissue Transfer Paper and of Printed Transfers for Transferring Designs on to Pottery Ware.* T. Phoenix, Newcastle-under-Lyme, and G. Kirk, Uttoxeter. Eng. Pat. 4264, March 11, 1889. 8d.

IN many cases it is desirable to print the designs on transfer paper immediately after it has been sized. Hitherto this has not been possible in the case of rolls of paper owing to the thinness of the paper. According to this invention the paper is first sized by leading it over the upper part of a roller, the lower half of which dips into a trough of size,

then passing it over a roller covered with india-rubber, which presses the paper against the engraved printing roller.—E. J. B.

*Improvement in Medicating, Odorising, and Disinfecting Paper.* W. W. Cosley, London. Eng. Pat. 4558, March 15, 1889. 4d.

TEREBENE is incorporated with the paper either in the course of manufacture or subsequently.—E. J. B.

*Improvements in the Treatment of the Recovered Ash of Paper Mills.* J. W. Kynaston, Liverpool, and J. Sutherland, Ballyclare. Eng. Pat. 5779, April 4, 1889. 6d.

IN the manufacture of paper the raw material is heated under pressure with caustic soda solutions. This becomes largely contaminated with silica and alumina from the fibre to the extent of about 15 per cent. of the whole soda present, as well as with various resinous products. The soda solution is thus both reduced in strength, and the impurities introduced are harmful in its further utilisation. The inventors add sodium bicarbonate to the solution converting any caustic soda present into the monocarbonate, the bicarbonate being simultaneously reduced. Under these circumstances the silica and alumina combine and are precipitated, especially on warming. The precipitate may be at once filtered off or removed with the calcium carbonate formed, when the liquors are causticised.—S. G. R.

*A Process for Producing Cupr-ammonia.* C. F. Hime, London, and J. H. Noad, East Ham. Eng. Pat. 7716, May 8, 1889. 4d.

See under VII., page 391.

*Improvements in Machinery for Refining and Finishing Half-Stuff in Paper Making, and in Hydrostatic Balances for Changing the Contents of the Pulp Reservoirs.* F. Faviers fils, Gromelle, France. Eng. Pat. 8509, May 22, 1889. 11d.

UNDERNEATH a beater of the ordinary form, but with the knives somewhat closer together, are placed two tanks with semi-circular bottoms, and provided with agitators. These tanks are connected with each other and with the overhead beater by means of pumps. One of the tanks being filled with half-stuff, the pumps are started and the "half-stuff" is pumped into the beater. It passes under the roll and then into the other chest. If necessary the pulp can be passed again through the beater.—E. J. B.

*Improved Method of and Apparatus for Recovering Chemicals from Solutions, or when mixed with Substances which are Volatilisable or Destructible by Heat, especially adapted for Recovering Soda from Waste Liquors of Pulp Digesters.* M. B. Mason, S. D. Warren, and F. Warren, Boston, U.S.A. Eng. Pat. 20,908, December 31, 1889. 8d.

THE principle of the process is very simple and can best be gathered by a description of the apparatus employed. The liquors to be treated are first evaporated to about 35° B., and then fed into the combustion chamber *b* of the furnace *A* by the pipe *a*<sup>2</sup>, which is in connexion with the pipe *a*. Attached to this latter tube also are pipes *a*<sup>1</sup> and *a*<sup>2</sup> regulated by cocks *a*<sup>1</sup>, by which steam and oil can be blown in respectively. The tube *a* acts as an "atomiser" or pulveriser. The oil is used to heat the chamber in the beginning of the operation; subsequently it can be shut off, and the temperature maintained by the combustion of the carbonaceous matter present in the liquors. The products of combustion pass through *b*<sup>2</sup> into the chamber *b*<sup>1</sup>, in which

is situated the boiler *C*, heated by ordinary tubes. The gases then pass to the condenser *c*, where any particles of soda, mechanically carried over, are washed out by the water-spray *f*, and the wash liquors are removed by the pump *D*. The fused soda in the chamber *b* flows out by the duct *b*<sup>3</sup> to the exterior, and is received in suitable vessels.

—S. G. R.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Report on New Drugs and Fine Chemicals.* Merck's Bull. 1890 [2], 9.

*Aluminium Aceto-tartrate.*—This salt is prepared in transparent, very faintly yellowish, crystalline granules, soluble in water, but insoluble in alcohol, ether and glycerol. Its value as a therapeutic agent is due to its caustic astringent properties, with which it combines further value as an energetic disinfectant. These properties were fully tested and ascertained in 1885 by Schäffer, of Bremen, and Lange, of Copenhagen. Mixed with boric acid or some indifferent

substance it is very effective in the destruction of nasal polyp (Berliner Klin. Wochenschr. 1889 [30]). A 50 per cent. solution is recommended by Michaelis as a wash for chilblains.

**Cocaine Phenate.**—This is a slightly coloured substance of the consistency of honey, readily melting when heated, and containing about 75 per cent. of the cocaine alkaloid. It is completely soluble in 50 per cent. alcohol, the solution possessing a faint odour of phenol. *Viau* (Nouveau Remède, 1887, 192) has found it, administered hypodermically, a very valuable local anæsthetic in dental operations. Experiments in 86 cases showed that complete topical anæsthesia is produced without any subsequent derangement. *Viau* uses an alcoholic solution of the salt of 0.08 per cent. strength (1 in 1,250). *Von Oefele* has employed cocaine phenate with success in nasal, gastric, conjunctival and other forms of catarrh. He finds also that painting or rubbing with a 1 per cent. solution of the phenate in 30 per cent. alcohol is effective for the treatment of all local pains.

**Salol.**—Löwenthal finds that Koch's "Comma Bacillus," which flourishes on a nutritive basis containing pancreatic juice, is speedily killed in the presence of salol, for the pancreatic ferment brings about the resolution of the salol into salicylic acid and phenol, which completely sterilise such a culture. He proposes large doses as a prophylactic, and larger still as a remedy for Asiatic cholera.

**Sodium Dithiosalicylate**, "No. 11."—(H. Baum, Ber. 22, Part 3 (Patents), 175). Dithiosalicylic acid is a compound of two molecules of salicylic acid connected by a two-atom molecular bond of sulphur—

The substance in question is the sodium salt of one of several isomeric acids. The discoverer distinguishes this particular isomeric acid as "No. 11," and its sodium salt, that under consideration, forms a greyish white and very hygroscopic powder, completely and easily soluble in water. From its solution the dithiosalicylic acid is precipitated in yellow viscid drops on the addition of stronger acids. *Lindenborn* (Frankfort-on-the-Maine) concludes as the result of a series of experiments, that sodium dithiosalicylate No. 11 is preferable to sodium salicylate in articular rheumatism, &c. (Berliner Klin. Wochenschr. 1889, 568). The preference is based on smaller dose required, prompt and reliable action and entire freedom from ill accessory effects. The antiseptic powers of the dithiosalicylate were found by *Hueppe* to be largely superior to those of the single salicylate.

**Zinc Permanganate.**—This salt forms crystalline granules of a violet-brown colour. Like the potassium salt it is very soluble in water. *Berkeley Hill* (Lancet, 1889, June 29th) has used it long and successfully in all forms of *Urethritis*. A special characteristic of the action of the drug was the total absence of any irritation. However, only very dilute solutions are to be used, such as one part of the salt in 4,000 of water. Like the potassium salt, this salt should never be compounded with alcohol, glycerol, sugar, or dry or fluid vegetable extracts, or there may be danger of explosions.

**Oxidation Products of Quinoidine.** H. Strache. Monatsh. 10, 642—646.

**CINCHOMERONIC** acid, which is at the present time obtained by the oxidation of quinine (Weidel and Schmidt's method), can be prepared at a smaller cost from the resinous by-products known commercially as quinoïdine, which are obtained in the preparation of quinine.

For this purpose the quinoïdine, reduced to pieces the size of hazel-nuts, is treated in quantities of 200 grms. with 3 kilos. of commercial concentrated nitric acid, and the mixture boiled for 5 to 6 days until ammonia produces no precipitate in the diluted solution, the acid which evaporates during the process being continually renewed; about 26 kilos. of acid are required for the oxidation of 800 grms. of quinoïdine. After evaporating the acid on the water-bath and repeatedly evaporating with water, a small quantity

(7.3 grms.) of the copper salt of  $\alpha$ -pyridine-tricarboxylic acid separates from the thick syrup in crystals. This salt is separated by filtration, the filtrate diluted with cold water, the solution filtered from the brown resinous precipitate, and then treated with excess of copper acetate. A green precipitate (A) is thus produced, and on standing for several days its quantity increases considerably. The acid filtrate is then evaporated, whereon most of the cinchomeronic acid separates in crystals; on standing for some time two further crops (B) of crystals are obtained, and finally crystals of cinchomeronic acid nitrate separate from the solution. On diluting the mother-liquors with a large quantity of cold water a resinous precipitate is formed at first, then a yellow substance (C) separates, and the filtrate from the latter yields, on addition of sodium acetate, a considerable quantity of a yellowish-green copper salt, which was not further investigated. The filtrate from this salt, after removing the copper with hydrogen sulphide and evaporating, yields a further crop of crystals of the same nature as (B).

The precipitate (A) contains the copper salt of  $\alpha$ -pyridine-tricarboxylic acid, free cinchomeronic acid, and a considerable quantity of a dark yellow amorphous compound. It is first repeatedly extracted with boiling water; the copper salt which remains, in an almost pure condition, is decomposed with hydrogen sulphide and the  $\alpha$ -pyridine-tricarboxylic acid recrystallised from hot water. The aqueous extract is evaporated, the residual cinchomeronic acid crystallised once from water and then dissolved in hot hydrochloric acid; on cooling, the hydrochloride separates in crystals.

The crystals (B) consist essentially of cinchonic acid which can be purified by dissolving in boiling water, precipitating with copper acetate, decomposing the copper salt with hydrogen sulphide, and recrystallising the acid from hot water with addition of animal charcoal.

The precipitate (C) contains a small quantity of cinchomeronic acid, which can be extracted by treating with dilute hydrochloric acid; the residue dissolves readily in hot concentrated hydrochloric acid, and on cooling the hydrochloride of nitroquinolinemonocarboxylic acid separates in crystals. This salt is decomposed on warming with water, yielding the free acid, and when sublimed it gives *La Coste's ana-nitroquinoline* in colourless plates melting at 153°—154°.

The quantities of the various products obtained by the oxidation of 800 grms. of quinoïdine with 26 kilos. of nitric acid, as described above, are as follows:—

73 grms. of  $\alpha$ -pyridinecarboxylic acid = 9.1 per cent., corresponding to 6.4 per cent. of cinchomeronic acid.

48 grms. of cinchomeronic acid hydrochloride = 6 per cent., corresponding to 4.9 per cent. of cinchomeronic acid.

34 grms. of cinchonic acid = 4.3 per cent., corresponding to 4.0 per cent. of cinchomeronic acid.

Total, 15.3 per cent. of cinchomeronic acid.

The quantity of cinchomeronic acid obtained by Weidel and Schmidt's method the author finds to be 44.2 per cent. of the alkaloids employed.

The cost of the materials (quinine, or quinoïdine and nitric acid) for the preparation of 100 grms. of cinchomeronic acid is about 22 M. when quinine is employed, and only about 11 M. when quinoïdine is used, but in the latter case the preparation is more troublesome.—F. S. K.

**Formation of Alkyl Derivatives of Orthohydroxyquinoline.**

E. Leppmann and F. Fleissner. Monatsh. 10, 665—672.

The hydriodide of methoxyquinolinehydroxyquinoline methyl iodide,—

is formed when hydroxyquinoline (1 mol.) is heated under pressure for some hours with methyl iodide (1 mol.) and methyl alcohol. The crystalline mass which is obtained is washed with a little water and then recrystallised from hot water. It forms lemon-yellow needles and melts at 143°. When treated with ammonia or sodium carbonate it is converted into methoxyquinolinehydroxyquinoline methyl iodide,  $C_9H_6N(OCH_3) + C_9H_6N(OH), CH_3I$ . This

base crystallises from alcohol in orange-red needles and is readily soluble in hot, but only sparingly in cold water, and insoluble in ether. It combines with methyl iodide, when heated therewith under pressure yielding the *methyl iodide* of methoxyquinolinehydroxyquinoline methiodide—

This compound crystallises in yellow needles with two molecules of water, and when treated with silver oxide in aqueous solution it is converted into *methoxyquinolinehydroxyquinoline ammoniummethyl hydrate*,  $C_{18}H_{16}N_2O_3$ .

Kairine is obtained, together with tetrahydromethoxyquinoline, when methoxyquinolinehydroxyquinoline methyl iodide (see above) is dissolved in hydrochloric acid and the calculated quantity of tin added to the solution in the course of about six hours. The reaction which takes place is expressed by the equation—

In order to isolate the kairine the tin double salt is separated by filtration, decomposed with hydrogen sulphide, the filtered and concentrated solution neutralised with sodium carbonate and the kairine extracted with ether; the crude reddish-brown product obtained in this way is mixed with resinous substances and changes on exposure to the air. By careful sublimation at  $100^\circ$  in an atmosphere of hydrogen it can be obtained in colourless needles, melting at  $114^\circ$ . The compound prepared in this way is identical with the kairine described by O. Fischer.

The tetrahydromethoxyquinoline formed in the above reaction cannot be isolated.—F. S. K.

#### *Hydroquinoline Derivatives.* O. Sreck. Monatsh. **10**, 701—720.

WHEN quininic acid is reduced with tin and hydrochloric acid it is converted into a tetrahydroquininic acid,  $C_{10}H_{12}NO_3$ , in which all four added hydrogen atoms are probably situated in the pyridine nucleus.

Tetrahydroquininic acid, when treated with bromine, yields tribromoquinanisol,  $C_{10}H_6Br_3NO$  (m.p.  $233^\circ$ ), identical with the compound obtained by Skraup from thalline; the formation of this compound may be represented by the equation—

Tribromoquinanisol is decomposed by hydrochloric acid yielding tribromohydroxyquinoline; both these compounds are formed when thalline is brominated in hydrochloric acid solution.

Tribromoquinanisol and tribromohydroxyquinoline both contain one bromine atom in the pyridine nucleus in the  $\gamma$ -position, and two bromine atoms in the benzene nucleus, because, on oxidation with nitric acid, tribromoquinanisol gives bromonicotinic acid (monobromopyridinecarboxylic acid), whilst tribromohydroxyquinoline yields bromoquinolinic acid (monobromopyridinecarboxylic acid) when it is treated with potassium permanganate.

Bromonicotinic acid, when fused with alkalis, gives two products, neither of which contains bromine; the one is an acid, the other is most probably  $\gamma$ -hydroxypyridine. It follows, therefore, that the bromine atom, both in bromonicotinic acid and bromoquinolinic acid, is in the  $\gamma$ -position. Tetrahydrobromohydroxyquinoline is obtained by the reduction of tribromohydroxyquinoline with tin and hydrochloric acid.—F. S. K.

#### *Phloroglucinol.* Z. H. Skraup. Monatsh. **10**, 721—725.

WHEN commercial phloroglucinol is treated with benzoic chloride and soda, diresorcinoltetrazobenzoate and phloroglucinoltribenzoate are obtained in about equal quantities; they can be separated, but only with difficulty, by repeatedly recrystallising from benzene.

*Diresorcinoltetrazobenzoate*,  $C_{22}H_{12}(C_7H_5O_2)_4$ , crystallises in prisms, melts at  $199^\circ$ , and is readily soluble in hot benzene,

but only sparingly in the cold, although, on cooling, it separates very slowly. In the partial "benzoylation" of commercial phloroglucinol almost the whole of the diresorcinol is contained in the first portions of the precipitate.

*Phloroglucinoltribenzoate*,  $C_6H_3(C_7H_5O_2)_3$ , crystallises in plates and melts at  $173^\circ$ — $174^\circ$ ; it shows the same behaviour as diresorcinoltetrazobenzoate with benzene, and like the latter, is very sparingly soluble in alcohol. It can also be obtained by boiling phloroglucinol with benzoic chloride.

The purity of phloroglucinol can be easily and quickly ascertained, even with only small quantities, by the following method: 0.1 gm. of the sample is treated in a test tube with 5 cc. of 10 per cent. soda, 0.3 cc. of benzoic chloride added, and the mixture shaken until the smell of the chloride is no longer perceptible. The solution is then filtered, the residue dissolved in a little hot benzene, and the solution boiled; if the crystals, which separate on cooling, melt at the right temperature ( $173^\circ$ — $174^\circ$ ) the sample is free from diresorcinol.

The complete purification of commercial phloroglucinol by the methods hitherto employed is not only a very troublesome, but also an uncertain process. When phloroglucinol is warmed with potassium carbonate it is almost immediately converted into the carboxylic acid at  $60^\circ$ — $70^\circ$ , whereas diresorcinol, under the same conditions, undergoes no change and is only slowly acted on even on boiling. When, therefore, Herzig-Zeisel's method of purification is employed, the diresorcinol passes into the ethereal extract, together with phloroglucinol and a little diresorcinolcarboxylic acid, and the smaller the quantity of substance employed, the larger the quantity of diresorcinol dissolved. By making use of Will's suggestion and extracting with ether before acidifying, this error can be eliminated, but the process becomes more troublesome.

The author finds that the purification of commercial phloroglucinol is best carried out as follows: One part of the finely divided sample is dissolved in one part of boiling water, the solution cooled quickly to  $60^\circ$ — $70^\circ$  in a water-bath, and then two parts of finely divided potassium bicarbonate added, the first half in small quantities at a time because of the effervescence, the second half all at once. The mixture is kept in the water-bath until it ceases to crystallise, then mixed with 6—8 parts of warm alcohol, shaken well and allowed to cool completely; it is advisable to keep the flask filled with coal-gas while it cools. The portion insoluble in alcohol consists of a mixture of potassium carbonate and the potassium salt of phloroglucinolcarboxylic acid, which is very sparingly soluble in alcohol or in potassium carbonate solution; the diresorcinol remains unchanged and dissolves readily in the alcohol. The solution is therefore filtered, the residue washed first with alcohol, then with alcoholic ether, and after drying for a short time in the air, triturated with a well-cooled mixture of two parts of concentrated hydrochloric acid and two parts of water until the evolution of carbonic anhydride is at an end. The solid phloroglucinolcarboxylic acid is then filtered off, washed with a little cold water and boiled with  $1\frac{1}{2}$  parts of water until the whole has dissolved, and the evolution of carbonic anhydride ceases. The pure crystalline product, which is deposited on cooling, is almost colourless and amounts to 50—60 per cent. of the substance employed. A further quantity can be obtained by evaporating the mother-liquors, and from the aqueous filtrate from the carboxylic acid.

In this way phloroglucinol can be easily prepared in a pure condition in the course of two hours; the method is especially convenient for the purification of small quantities, but it can doubtless be employed for the treatment of large quantities as the fact that ether is not used in the process compensates for the slight amount of loss.—F. S. K.

#### *Kynurine.* Z. H. Skraup. Monatsh. **10**, 726—731.

It has been previously shown that kynurine (hydroxyquinoline) is formed in the oxidation of cinchonine and cinchoninic acid; it is also produced in relatively large quantities in the oxidation of cinchonidine, whilst quinine yields neither kynurine nor any analogous compound.

The preparation of kynurine from cinchoninic acid is described below. The process is rather troublesome, but as the yield is about 10 per cent. of the weight of the acid employed, it is more convenient than that by which kynurine was first obtained, namely, from the urine of the dog.

A solution of 50 grms. of anhydrous cinchoninic acid, 20 grms. of chromic acid, and 30 grms. of concentrated sulphuric acid, in about 200 cc. of water, is evaporated on the water-bath until it becomes deep brown, and the heating is then continued until the colour changes to green, the water lost by evaporation being continually renewed. This operation occupies about 20 hours. The green solution is then mixed with a large volume of water, and allowed to cool completely, whereon the unchanged cinchoninic acid is deposited. After further concentration, a second crop of this acid is obtained. The solution is then poured into excess of cold potash, the organic salts separated from the chromium hydroxide and inorganic salts in the usual manner, and the aqueous solution freed from potassium sulphate by mixing with alcohol. Copper sulphate is then added as long as copper cinchoninate is precipitated, and the filtered solution slightly acidified with hydrochloric acid. After standing for some time, the kynurine separates as a basic salt in long needles; the weight of this product is about 4 grms. The mother-liquors, which still contain cinchoninic acid and kynurine, are evaporated, the inorganic compounds separated, and, after precipitating the cinchoninic acid with copper sulphate, the kynurine precipitated with soda.

The kynurine obtained by the oxidation of cinchoninic acid is identical with the compound obtained from cinchonine and from kynurinic acid.

When kynurine is boiled with potash and ethyl iodide it yields a quaternary iodide and two kynurine ethyl ethers; when treated with phosphorus oxychloride and phosphorus pentachloride at 100°—110° it is converted into a chloroquinoline which melts at 34°, and is not identical with  $\alpha$ -chloroquinoline.—F. S. K.

**Codeine Methylolide.** Z. H. Skraup and D. Wiegmann. *Monatsh.* **10**, 732—733.

WHEN codeine methylolide is heated with alcoholic potash it yields ethyldimethylamine and a small quantity of trimethylamine, but not dimethylamine, as stated by Knorr. This fact is in accordance with the authors' view, that the nitrogen atom in morphine is directly combined both with a methyl- and an ethyl- group. The two bases obtained in this way can be easily separated by fractional crystallisation of their platinichlorides, the double salt of ethyldimethylamine separating in compact octohedra, which melt at 193°, and are very readily soluble in water, but only sparingly in alcohol.

Numerous experiments on the behaviour of various samples of morphine and codeine methylolide with alcoholic potash show that the two compounds exhibit no noteworthy difference in behaviour, and give no grounds for doubting that morphine is a distinct chemical compound.

—F. S. K.

**Methysticine.** C. Pomeranz. *Monatsh.* **10**, 783—793.

CUZENT, in 1861, obtained a crystalline neutral substance, which he named "Kawain," from the roots of *Macropiper methysticum*, one of the piperaceæ indigenous to the Polynesia, and termed Kawa-Kawa or Ava-Ava by the natives, by whom it is employed for the preparation of an intoxicating beverage. At about the same time Goble and Rorke obtained from the kawa-root, in the same way, a substance which, though resembling kawain in its properties, they named methysticine.

Methysticine,  $C_{15}H_{11}O_5$ , was prepared by the author from kawa-root according to the method described by Cuzent (*Compt. Rend.* 1861, 205) and Goble (*Jour. Pharm. Chim.* 1860, 598). The powdered root is extracted with 80 per cent. alcohol, the alcoholic solution concentrated, and then kept for some time in a cool place; the crystals which are deposited are separated, the mother-liquors concentrated again in order to obtain a further small quantity of crystals, and the product is then purified by repeated recrystallisation

from 70 per cent. alcohol with the addition of animal charcoal. It is thus obtained in colourless, tasteless, silky needles, which melt at 137°. It is insoluble in cold water, and only sparingly soluble in hot water, light petroleum, and ether, but more readily in alcohol, benzene, and chloroform, and most readily in boiling alcohol. It decomposes when heated, giving off aromatic vapours; when treated with concentrated sulphuric acid it turns purple-violet. It is insoluble in cold potash or soda, but on boiling it gradually dissolves, and crystals of a salt of methysticine acid separate from the solution on cooling.

**Methysticine Acid**,  $C_{14}H_9O_5$ , is best prepared by boiling 10 grms. of methysticine for 20 minutes with 300 cc. of 6 per cent. potash and acidifying the cold solution with acetic acid; the precipitate is washed with water and crystallised twice from boiling 90 per cent. alcohol with the addition of animal charcoal. Five grms. of the acid are obtained in this way. It forms yellowish, silky needles, very like the crystals of piperinic acid in appearance, and melts at 180° with evolution of carbonic anhydride. It is much more sparingly soluble in hot alcohol than methysticine, and it is only sparingly soluble in chloroform, ether, and benzene, but it dissolves freely in alkalis and alkaline carbonates; its alcoholic solution gives a red colouration with ferric chloride.

If methysticine is boiled with alkalis for more than about 20 minutes the solution becomes turbid, owing to the decomposition of the acid, one of the products being piperonal. When methysticine acid (4 grms.) is dissolved in 200 cc. of 3 per cent. potash, the solution heated to boiling, and then 200 cc. of a 3 per cent. solution of potassium permanganate gradually added, the acid is rapidly oxidised and a strong odour of piperonal is observed. When the filtered solution is distilled a small quantity of a crystalline substance passes over; this compound melts at 37°, and possesses the odour of piperonal, with which it is most probably identical. On acidifying the residual solution (about 60 cc.) with hydrochloric acid, piperonylic acid is precipitated; the yield of this product is 0.7 gm. from 4 grms. of methysticine acid.

A compound of the composition  $C_{13}H_{12}O_3$ , which the author names *methysticol*, is obtained when methysticine is boiled with 40 parts of 4 per cent. hydrochloric acid for 15 minutes, or when methysticine acid is boiled with dilute mineral acids. It crystallises in flat prisms, melts at 94°, and is insoluble in alkalis; it is not acted on by acetic anhydride at 160°, but it combines with phenylhydrazine, yielding a hydrazide which melts at 143°.

The author's experiments show that methysticine is the methyl salt of methysticine acid, and that this acid has the constitution—

Judging from its chemical behaviour, which resembles closely that of a  $\beta$ -ketone acid, methysticine acid is probably a piperinyllactic acid of the constitution—

—F. S. K.

**The Compounds of the Volatile Fatty Acids with Phenols.**  
M. Nencki. *Monatsh.* **10**, 906—907.

THE author prepares the oxyketones containing a fatty acid and phenol radiæly by heating the phenol and fatty acid with zinc chloride. He has prepared in this way the acetyl phenols of resorcinol, orcinol, quinol, and pyrogallol. Formic acid and phenol under similar conditions yield leucaurin. Propionic acid, butyric acid, and valeric acid also combine with phenols in presence of zinc chloride. Propionyl phenol is obtained by heating 2 parts of zinc chloride dissolved in 1 part of propionic acid, adding 1 part

of phenol, and boiling for 5–10 minutes. On oxidation with fused potash, it yields *p*-hydroxybenzoic acid. The propionyl group occupies, therefore, the para-position to the hydroxyl group.—J. B. C.

*Frangulin.* T. E. Thorpe and H. H. Robinson. J. Chem. Soc. **57**, 38–50.

This body has been previously investigated by several authors, but the statements concerning it differ considerably. The authors prepared it from the bark of the alder buckthorn (*Rhamnus frangula*) by extracting it, first with low-boiling petroleum, which dissolves only fat and chlorophyll, and then with methylated spirit, which dissolves the frangulin and other matter. The methylated spirit extract deposited a quantity of resin on standing for two days. The tannin was removed by lead acetate, and the excess of lead by sulphuretted hydrogen. The clear solution after this treatment, on standing for five weeks, deposited some frangulin. The mother-liquor was evaporated and mixed with calcium sulphate in order to form a powder suitable for extraction with ether. This extract deposited more frangulin. Altogether 0.09 per cent. was obtained.

It is an orange-yellow crystalline powder, very slightly soluble in cold alcohol and not much more soluble in hot alcohol. Melting point 225°.

The mean of seven closely-agreeing analyses of different specimens dried at 120° gave 61.20 per cent. carbon and 5.29 per cent. hydrogen. If the formula of the body be  $C_{20}H_{22}O_9$ , it would contain 61.40 per cent. of carbon and 5.11 per cent. of hydrogen.

It was hydrolysed by boiling with hydrochloric acid in alcoholic solution for 3–4 hours. On boiling off the alcohol and diluting with water an orange-yellow precipitate was separated. This amounted to 67.6 per cent., and was found to be emadin ( $C_{15}H_{10}O_5$ ). There then remained in solution a body possessing the power of reducing Fehling's solution. A phenylhydrazine derivative was prepared by evaporating the solution to dryness with sodium acetate and phenylhydrazine hydrochloride (cf. Beythien and Tollens, Ann. **225**, 217–221; this Journal, 1890, 310). The residue, insoluble in water, was dissolved in alcohol, and precipitated by water; it had a melting point of 158°, and was not phenylglucosazone.—A. L. S.

*Norwegian Oil of Carraway.* C. Nicolaysen. Chem. Zeit. **13**, 1704.

THE carraway is one of the most widely distributed plants in Norway, growing as far north as 71° of latitude, and, in Southern Norway, up to 1,098 m. above the sea level. The author has examined the seeds of Norwegian carraway by passing steam through 5 kilos. of the bruised seeds contained in an iron still, obtaining 6.1 per cent. and 6.4 per cent. of oil in two experiments, but of this a considerable proportion was contained in the aqueous distillate, which had to be treated with ether to recover the dissolved oil. Carraway oil consists of carvene and carvol, the latter being the most valuable. Three samples gave, by fractional distillation, 48.9, 47.1, and 48.0 per cent. of carvol respectively, which is less than the average continental oil containing about 64.5 per cent. of carvol and 35.5 per cent. of carvene.—G. H. B.

*Dilution Tables for Practical Use.* F. J. Herz. Chem. Zeit. **14**, 3–4.

IN order to avoid troublesome calculations, it is proposed to have dilution tables for acids, lyes, and solutions of salts, by means of which the amount of diluent required may at once be found. As an example, spiritus dil., of the German Pharmacopœia, contains 60 to 61 per cent. (by weight) of ethyl alcohol; in order to dilute 100 grms. of 86 per cent. alcohol to the above strength, 41 to 43 cc. of distilled water has to be added. 1,000 grms. of 90 per cent. alcohol give with 475 cc. of water 61 per cent., and with 500 cc. water 60 per cent. alcohol. Tables for alcohol and for ammonia are given.—N. H. J. M.

*Iodine Cotton-Wool.* Bréaudet and Cathelineau. Rép. de Pharm. **45**, 529.

ETHEREAL and alcoholic iodine solutions, when brought into contact with the skin, irritate and even cauterise, whilst the absorption of iodine is limited. Good results are obtained by using iodine cotton-wool, from which the iodine is liberated by very gentle heat. It is prepared as follows:—Carefully cleaned cotton-wool is put for a few minutes into 2 per cent. aqueous sodium carbonate, washed and then kept for half an hour in 4 per cent. bleaching powder solution. It is washed until free from alkali and kept for a quarter of an hour in water acidified with 5 per cent. hydrochloric acid; it is again washed and dried. Finely powdered iodine (8 parts) is strewn over the sheets of cotton-wool (100 parts), which is then tightly rolled together and heated in a glass bottle until iodine vapour is given off. The bottle is then stoppered and heated for two hours in a water-bath. The iodine cotton-wool is kept in well-closed glass vessels.—N. H. J. M.

*The Poisonous Constituents of Castor-Oil Seeds.* H. Stillmark. Pharm. Central-halle, **30**, 650.

A DIASTASIC ferment called "*Ricin*" is extracted from castor-oil seeds as follows:—Fresh, shelled seeds are ground to a powder and agitated with a 10 per cent. solution of sodium chloride. The solution is filtered, saturated at the ordinary temperature with magnesium sulphate and sodium sulphate at the same time, and then allowed to stand. Large crystals of the two sulphates separate out, and in addition a white amorphous precipitate which can be readily separated from the crystals and collected. This is the substance ricin. It is purified by repeated dialysis at a low temperature and then dried in vacuum over strong sulphuric acid. Thus prepared it forms a white friable powder, free from taste and smell and very poisonous; it still contains 10–20 per cent. of sulphates. It loses its toxic properties when boiled, but keeps perfectly in the substance. A 10 per cent. solution of sodium chloride is the best solvent for it. It appears that similar poisonous albuminoid bodies exist in other species of *Recinus*, and also in the seeds of *Croton tiglium* and of *Jatropha caracas*.—C. A. K.

*A New Antipyretic.* R. Kobert. D. Medecin. Wochenschr. 1890, No. 2.

THE name *Orthin* is given by the author to orthohydrazine-para-hydroxybenzoic acid ( $\text{OH:N}_2\text{H}_3\text{:CO.OH} = 1:2:4$ ). The free base is very unstable, but the hydrochloride is a stable body which reduces the per-salts of the heavy metals and which possesses a marked antiseptic action. Experiments with animals have shown that it can be administered without injurious results, and that a single dose suffices to render the body proof against the action of reducing agents for weeks. It is probable that orthin hinders the processes of oxidation going on in the system, and that it reduces the temperature by increasing the ease with which heat is given up by the body, by extending the pores of the skin. Solutions of 1 to 10,000 of orthin had no injurious effect on the heart of a frog. Para-hydrazine salicylic acid has a similar physiological action to its isomer, orthin. The author does not consider that the latter is likely to be much employed as an antipyretic.—C. A. K.

#### PATENTS.

*New or Improved Manufacture of Periodides of Phenols and Salicylic Acid.* B. Wilcox, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 5079, March 23, 1889. 6d.

NEW iodine substitution products, or periodides of phenol, cresol, resorcinol, thymol,  $\beta$ -naphthol, and of phenol carboxylic acids result by the treatment of the aqueous alkaline solutions of these bodies with a solution of iodine in an alkaline iodide. According to the nature of the phenol or of the phenol carboxylic acid, the amount of iodine

entering into reaction varies; but in all cases the hydrogen of the hydroxyl group is replaced by iodine, *e.g.*, in the case of thymol:—

One-half of the iodine is apparently lost in this process, but the filtrate from the iodo-thymol iodide is again treated with an alkaline solution of thymol and the iodine in the sodium iodide liberated by the addition of bleach or of other hypochlorites. The iodo-thymol iodide is a brown-red amorphous powder, which gradually loses iodine in the air, readily when heated to form mono-iodo-thymol; it melts with decomposition at 110° C. The red colour of this product is removed by treatment with sodium hyposulphite; it is insoluble in water, soluble in alcohol and ether. The other phenol iodides described possess similar properties. Those of salicylic and cresol carboxylic acids are odourless and insoluble in alkalis, that of  $\beta$ -naphthol is an amorphous green yellow precipitate, insoluble in water and readily reconverted into  $\beta$ -naphthol. Details for the preparation of the thymol and  $\beta$ -naphthol compounds are given.

—C. A. K.

*A Process for the Production of a Substance to be called Chloral Formamide or Chloralamide.* J. F. von Mering, Strasburg, Germany. Eng. Pat. 7391, May 3, 1889. *Ad.*

By warming chloral and formamide together in molecular proportions, chloral formamide ( $\text{C}_2\text{H}_3\text{Cl}_3\text{COH}\cdot\text{COH}\cdot\text{NH}_2$ ) is obtained. The recrystallised product forms colourless crystals with a mild and slightly bitter taste, and without smell; soluble in water, alcohol, ether, &c., and melting at 115°–116° C. It is more stable than chloral, but acts like the latter as an hypnotic or soporific, and as an antiseptic. It has no corroding action, does not affect the action of the heart, and does not disturb the digestion.—C. A. K.

## XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

*"Flash Powder" Explosions.* C. L. Mitchell. Phot. News, 34, 191–192 and 225–226.

THE author calls attention to the great danger attending the use of mixtures of magnesium powder with picric acid, potassium chlorate, &c. The substances which have been employed in conjunction with magnesium are potassium ebhorate, nitrate, dichromate, and permanganate, amorphous phosphorus, picric acid, sulphur, antimony sulphide, and possibly some others. Five deaths have recently been caused in America by the explosion of one of these powders either in the process of mixing, or, in one case which caused three deaths, whilst being handled 18 months after preparation. Picric acid was one of the chief constituents of this powder, and the excessive explosibility may have been due to the presence of sodium or potassium picrate, which is frequently found in the commercial acid. In the case of the powder which had been kept for some time there was evidence that magnesium picrate had been formed by the gradual action of the acid on the metal, an action doubtless assisted by the hygroscopic nature of the powder.—C. H. B.

*Photo lithographic Ink containing Gum Elemi.* K. Kampmann. Phot. Correspondenz, 26, 564–568.

ASPHALT, 20 parts, and colophony, 100 parts, are dissolved in turpentine, 40 parts, and mixed with yellow wax, 20 parts, suet, 140 parts, gum elemi, 230 parts, Marseilles soap, 30 parts, linseed oil varnish (medium strength), 60 to 80 parts, finest lamp black, 80–100 parts. Instead of the soap, 20 parts of Venice turpentine and 40 parts of good transfer ink may be used.

The materials must be well melted together and very thoroughly mixed, an operation requiring much care and practice. The materials should be as free from water as possible, the vapours should not be allowed to burn, and towards the close of the operation the mixture should be heated in an uncovered vessel until it is completely melted.

This ink is especially valuable when working on zinc, but works equally well on stone.—C. H. B.

*Intensification of Collodion Negatives by Means of Quinol.* v. Huhli and Eder. Phot. Correspondenz, 27, 14–16.

TWO solutions are required:—(A.) Quinol, 10 parts, citric acid, 6 parts, water, 1,000 parts; and (B.) Silver nitrate, 1 part, water, 30 parts. One volume of B. is added to 3 vols. of A., and the mixture poured on the unfixed collodion negative. Not only is the existing image intensified, but development is extended, and new details become visible.

The intensifier can also be used after the negative has been fixed, provided that comparatively little intensification is required.—C. H. B.

*New Positive Printing Process.* Amer. Am. Phot. 1890, 232.

PAPER is coated with an emulsion containing ferric oxalate 7 parts, silver nitrate 7 parts, gelatin 7 parts, tartaric acid 3 parts, and water 128 parts. The images are printed out, have a pleasant brown colour, and are fixed in the usual way.—C. H. B.

*Ferric Oxalate as a Reducer.* L. Belitski. Phot. Wochenblatt, 16, 71–73.

TEN parts of ferric potassium oxalate, 8 parts of normal sodium sulphite, 2.5 to 3 parts of oxalic acid, and 50 parts of sodium thiosulphate are dissolved in this order in 200 parts of water and the solution filtered and kept in the dark. It can be kept unaltered for a long time in closed vessels, but becomes yellow and deposits sulphur on prolonged exposure to air. When brought in contact with a negative part of the silver is dissolved and ferric oxalate is reduced. The ferrous oxalate formed takes up oxygen from the air and thus the activity of the reducer continues for a long time.

—C. H. B.

## PATENT.

*Improvements in and in Connection with Photographic Printing.* W. W. J. Nicol, Birmingham. Eng. Pat. 5374, March 29, 1889. 6d.

PAPER, wood, or any other surface is sensitised with a ferric salt, with a salt of an organic acid which prevents precipitation of the iron by ammonia. It is then exposed to light under a negative, &c., until a faint image is visible, and is developed by treating it with an ammoniacal solution of silver nitrate containing a salt of an organic acid. The print is washed with water containing ammonia and an organic salt, and finally with pure water. A solution (1) containing 20 per cent. of ferric sodium citrate and 5 per cent. of potassium oxalate gives very good results. A solution (2) containing 5 per cent. of normal ferric oxalate, 5 per cent. normal ferric tartrate, and 1 per cent. of tartaric or oxalic acid also works well, but the developing solution requires modification in order to prevent precipitation of the iron.

If necessary the sensitising solution may be thickened with gelatin, starch, &c. Paper sensitised with solution (1) may be developed with one of the following solutions: (a) for cold blue-black tones, 20 per cent. of potassium oxalate, 1.5 per cent. silver nitrate; (b) neutral black

tones, 10 per cent. of potassium oxalate, 1.5 per cent. silver nitrate; (c) *sepia tones*, 7 per cent. borax, 1.5 per cent. silver nitrate. In all cases the precipitated silver salt is nearly redissolved by adding ammonia.

If the paper has been sensitised by solution (2) the following developers may be used: (a) 15 per cent. potassium citrate, 10 per cent. sodium acetate, 1.5 per cent. silver nitrate; or (b) 10 per cent. of potassium oxalate in place of sodium acetate. In both cases the precipitate is redissolved by ammonia. The first series of developers may also be used, but in this case the print after development must be immersed for a short time in a clearing solution containing 20 per cent. of an alkaline citrate or tartrate made alkaline with ammonia. The developed prints are first washed in a solution prepared by mixing a 25 per cent. solution of an alkaline citrate or tartrate with an equal volume of strong ammonia solution, and diluting 150 cc. of this mixture up to 10 litres with water. They are afterwards washed with water and dried.

Development and the other operations are conducted at the ordinary temperature. The process is applicable to fabrics as well as to glass and paper.—C. H. B.

## XXII.—EXPLOSIVES, MATCHES, Etc.

### PATENTS.

*Improvements in the Preparation of Explosive Compounds.*

A. V. Newton, London. From A. Nobel, Paris, France. Eng. Pat. 4479, March 14, 1889. 6d.

This invention consists in incorporating with nitroglycerin and nitrocellulose an acetic ether of glycerin or analogous non-volatile solvent for the purpose of producing explosive compounds of determinate degrees of explosive sensitiveness.

It has been found that explosive compounds produced according to Eng. Pat. 1471 of 1888 (this Journal, 1889, 214), alter on keeping owing to the volatilisation of the camphor. This defect is now obviated by the use of the non-volatile tri-acetin. The explosive made according to this specification when used for blasting purposes may either be fired by a spark or fuse or ordinary detonator, according as a slow or quick action is desired, and it is found advantageous to compress it into cartridges, the grains readily adhering together when slightly warm, or after having been moistened on their surface with a solvent such as acetate of amyl, and then subjected to gentle pressure.—W. M.

*Improvements in and connected with the Manufacture of Matches, and in Machinery or Apparatus therefor.*

C. R. E. Bell, Wandsworth. Eng. Pat. 5208, March 26, 1889. 11d.

This is an invention for a "continuous process of match making by means of an automatic machine, into which the veneers are fed, and by means of which the veneers are cut into splints, the splints inserted into grippers carried by an intermittently rotating drum and tipped and dried through the rotation of the drum and the matches delivered in a shoot or boxes." Numerous drawings and detailed description are given in the specification.—W. M.

*Improvements in the Manufacture of Explosives.* C. O. Lundholm and J. Sayers, Stevenston. Eng. Pat. 6399, April 15 1889 4d.

The principal feature in this invention is the employment of suitably nitrated hydro- or oxy-cellulose instead of the usual nitrated celluloses. The nitrated substance is subsequently treated with camphor or with camphor in solution for the purpose of consolidating the explosive, and the treatment is varied so as to obtain different densities of grains, and consequently different rates of combustion. The nitrated substance may also be mixed with nitroglycerin and nitrates, chlorates, picrates, or picric acid.—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

*Extraction Apparatus.* O. Knöfler. Zeit. Anal. Chem. 28, 671—672.

The author describes with the aid of a diagram a form of extraction apparatus, which has the advantages of being cheaper than, and not so fragile as the ordinary Soxhlet's extractor, whilst the solvent action takes place at the boiling point of the liquid employed.

The substance is placed in a small cylindrical glass vessel B, which is open above but closed below; through the

lower conical extremity of B passes a U-shaped syphon H. The vessel B is surrounded by a cylinder A, the two being kept a short distance apart by small glass knobs *g g* on the outside of B; the lower extremity of A is drawn out and passed through a cork into the flask C containing the solvent, the upper extremity being closed with a cork, through which projects the tube of an ordinary Liebig's condenser K.—F. S. K.

*Apparatus for Fractional Distillation under Reduced Pressure.* E. Valenta. Zeit. Anal. Chem. 28, 673—676.

The author describes with the aid of diagrams an apparatus for distilling under reduced pressure, suitable more especially for substances which are solid at the ordinary temperature.

The substance is heated in a fractionating flask, provided with a short fractionating column which is connected by means of an adapter to an ordinary Liebig's condenser, kept at from 40° to 80° by a stream of warm water. The cylindrical receiver is funnel-shaped below, a three-way stop-cock being situated on the stem of the funnel, which serves to connect the receiver with a small flask or test-tube in the usual way. The cylindrical receiver is kept at a suitable temperature by means of a hot-water jacket.—F. S. K.

*A New Gas Balance.* F. Lux. *Zeits. Anal. Chem.* **29**, 13—18.

THIS is the latest and most improved form of the author's gas balance originally described in the *Zeits. Anal. Chem.* **28**, 38 (also this Journal, 1888, 95; and 1889, 668). It is known as the form C.E.

The balance is fitted into a glass case, provided with levelling screws and a hinged window in the front (not shown in the Figure). The central support is a hollow brass

cylinder with a forked top, which latter carries the agate planes of the pivot of the balance, these being fixed in suitable grooves. On either side of these grooves are carriers for the ivory cups, which are filled with mercury and act as lutes for the entrance and exit of the gas. Screws are attached to these carriers, to allow a thermometer and manometer to be fixed on when required, so that the temperature and pressure of the gas can be taken (shown in the Figure). The gas supply and exit pipes are attached just below the carriers referred to. Inside the central

column is placed the adjustment for bringing the balance to rest; the method employed is described as the "cylindrical adjustment." A mill-headed screw placed above the axis of the beam serves to free or to arrest the latter. The other essential parts of the balance are the hollow brass sphere which is filled with the gas and a six-sided beam with a divided scale and a serrated edge to accommodate a rider. At the end of this beam a pointer is attached reaching to the ivory scale shown in the Figure; the beam is divided into 10 parts, and each part again into tenths (0.1, 0.2, &c.). The scale is divided into 50 parts in a similar way, with the zero point in the centre and the signs + and - above and below the zero point respectively.

To use the balance the case is first levelled, the ivory cups of the main support filled with mercury, and then the beam placed in position and screwed firmly down so that it cannot move. The rider (which is made of nickel) is then placed on division 1 of the beam and the beam released. The pointer should rest at the zero of the ivory scale. If it does not, adjustment can be made by a suitable screw. The rider is then placed in a second position on the beam, so as to see whether each one division on the beam corresponds to one division on the scale. This done the beam is fixed in position and the gas to be tested passed in. Under a pressure of 25 mm. of water five minutes is ample to completely displace all the air in the sphere. The rider is then placed on a suitable division (0.4 for coal gas) and the beam released. The reading on the beam + or - the reading on the scale gives at once the specific gravity of the gas. The 25 divisions on the scale give a range of from 0.15 to 0.65 in specific gravity, so that without changing the position of the rider the specific gravity of the gas is got at once, except in very exceptional cases. The author considers this new form of gas balance just as convenient and considerably more accurate than the older form (form C.).—C. A. K.

*Drying of Gases.* J. D. van der Plaats. *Rec. trav. Chim.* **6**, 45.

DEHYDRATED calcium chloride absorbs water better than the salt containing two molecules of water of crystallisation, but the difference at low temperatures is slight. Calcium chloride dried at 180° always contains caustic lime, which cannot be reconverted into a calcium salt by prolonged treatment with hydrochloric acid or with carbon dioxide as long as it remains dry. Caustic lime only absorbs moisture slowly, and leaves twice as much water in the gas to be dried as the calcium chloride with two molecules of water of crystallisation does. Fused caustic potash acts more rapidly and more efficiently than calcium chloride, but less so than sulphuric acid. Phosphorus pentoxide is the best drying agent. According to Stas, it can be freed from phosphorous anhydride by distillation in a current of dry air. Sulphuric acid is the most convenient substance for drying gases, and removes the moisture completely, even from a rapid current of gas. Its efficiency is greatest at low temperatures. It should be free from sulphur trioxide, and to make quite sure on this point it is advisable to use acid containing 6—8 per cent. of water. Carbon dioxide is kept back to some extent by strong sulphuric acid, but is readily driven out again by a current of air. In using pumice soaked in sulphuric acid for drying purposes, the author recommends that the pumice should be first boiled with a mixture of strong sulphuric acid and a little nitric acid, so as to remove chlorides, fluorides and oxides likely to absorb oxygen.—C. A. K.

*A Rapid Method for the Detection and Estimation of Chlorine in Alkaline Sulphocyanides.* C. Mann. *Zeits. Anal. Chem.* **28**, 668—669.

WHEN a stream of hydrogen sulphide is passed through a solution of an alkaline sulphocyanide mixed with copper sulphate, the colourless copper sulphocyanide which is precipitated at first is only slowly converted into black copper sulphide. When, however, more copper sulphate is present than is necessary for the formation of copper sulphocyanide, and the current of gas is stopped just when the solution begins to turn brown (*i.e.*, when the formation of copper sulphide commences), after adding more copper sulphate to combine with the hydrogen sulphide in solution and to precipitate the free hydrogen sulphocyanide, and filtering, the filtrate will be free from sulphocyanides. The precipitate can be rapidly separated by filtration, and the solution shows

*Impurity in Commercial Barium Carbonate.* R. Weysscheider. *Zeits. Anal. Chem.* **29**, 20.

THE author found traces of zinc and iron in a sample of commercial barium carbonate. Fresenius found a considerable quantity of manganese in another sample.

—C. A. K.

no tendency to pass through turbid, even after repeated washing.

The presence of very small quantities of chlorine (or bromine) can then be detected by acidifying the filtrate with nitric acid and adding a few drops of silver nitrate solution.

For estimating the chlorine, 5 grms., at the most, of the sulphocyanide are dissolved in 100 cc. of water, and the solution mixed with 20 grms. of copper sulphate in 100 cc. of water; hydrogen sulphide is then passed until the solution begins to turn brown, then 8 grms. of copper sulphate dissolved in 40 cc. of water are added, and the mixture stirred well, and filtered.

Quantitative experiments with mixtures of ammonium sulphocyanide and ammonium chloride gave very good results. Commercial ammonium sulphocyanide rarely contains more than a trace of chlorine.—F. S. K.

*Estimation of Copper by Converting Copper Sulphide into the Oxide.* C. Holthof. Zeits. Anal. Chem. **28**, 680—681.

WHEN freshly-precipitated and moist copper sulphide, in quantities of 0.18—0.22 gm., is heated in a porcelain crucible, it commences to glow, and is converted into copper oxide. After heating for 7 to 10 minutes over a good Bunsen burner, the change is complete, no further decrease in weight takes place, and the residue is completely free from sulphuric acid.—F. S. K.

*Volumetric Determination of Sulphuric Acid.* A. Gawalowski. Zeits. Anal. Chem. **29**, 19.

THE author, in reply to adverse criticisms of his method for the volumetric determination of sulphuric acid (this Journal, 1888, 455), says he has reviewed his data carefully, and finds the method, as originally described, trustworthy as long as all details are carefully attended to.—C. A. K.

*Analysis of Chrome Iron Ore.* R. Fresenius and E. Hultz. Zeits. Anal. Chem. **29**, 29—35.

A SAMPLE of chrome iron ore which was finally shown to contain 61 per cent. of chromium, 28 per cent. of iron, and 9 per cent. of chemically combined carbon and graphite, and which was hardly attacked by acids, was analysed by the following method:—

1. *Determination of Metals and Gangue.*—About 5 grms. of the ore are heated in a boat in a current of dry chlorine. The boat is placed inside a combustion tube, attached to one end of which are a number of Peligot's flasks and Woulff's bottles partially filled with water, for absorbing the volatilised chlorides. After 3—4 hours' chlorination, the absorbing vessels are removed, and the chlorine in the tube displaced by dry carbon dioxide. The contents of the boat and any sublimed chromic chloride in the tube are reheated and a current of hydrogen passed through the tube, to reduce any chromic to chromous chloride and render it soluble in water; a fresh Peligot's flask is attached on passing the hydrogen. The boat is withdrawn on cooling, and its contents extracted with water; manganese chloride and any chloride of iron or of chromium is dissolved, whilst the carbon, gangue and undecomposed ore remain behind. These are filtered, washed, &c., and ignited in a current of oxygen, so as to burn off the carbon, then heated in a current of hydrogen to reduce any ferric oxide formed, and finally the residue once more subjected to the treatment with chlorine. After the second treatment the insoluble portion of the residue is weighed as gangue. The solutions obtained from these two operations together with the contents of the absorption flasks are acidified with a measured volume of hydrochloric acid of sp. gr. 1.1 and allowed to stand. Any insoluble matter is filtered off and fused with a mixture of sodium carbonate and potassium chlorate; the melt is then extracted with water and this extract added to the main solution. The residue (A) is weighed. The solution is transferred to a flask, the weight of which is approximately known, and so much sodium carbonate is added that the

resulting solution contains about 4 per cent. of hydrochloric acid of sp. gr. 1.1. In this solution the metals of the copper group are precipitated by a current of sulphuretted hydrogen and separated as usual. The filtrate is evaporated to dryness to separate the silica, which is filtered off, and weighed together with the residue A. When coloured it is refluxed with sodium carbonate and nitre and the bases removed; if it be white the silica should be determined by treatment with hydrofluoric acid and the residue tested for titanate. The filtrate from the copper group is oxidised with chlorine, nearly neutralised with sodium carbonate and precipitated with barium carbonate.

The filtrate containing nickel, manganese, cobalt and zinc together with barium carbonate, is treated as usual. The residue, containing the iron and chromium, is dissolved in hydrochloric acid and made up to 1 litre, of which 200 cc. are taken, evaporated to dryness, and fused with sodium carbonate and potassium chlorate. The fused mass is extracted with water and the residue fused again. The iron is determined in the insoluble portion of the extract and the chromium in the filtrate by the usual methods, care being taken to note the presence of alumina and of phosphoric acid, and to determine them if present.

2. *Determination of the Total Carbon, Phosphorus, and Sulphur.*—Another 5 grms. of the ore are decomposed as in (1) in a current of chlorine; the residue washed first with water and hydrochloric acid, to which a little chromous chloride is added, and then with water, and the dried residue oxidised by chromic and sulphuric acids, the evolved carbon dioxide being collected and weighed. The phosphorus and sulphur of the ore are contained in the absorption vessels, after the ignition, in the form of sulphates and phosphates. They are estimated as usual, after separating any silica present, by evaporation with sodium chloride.

3. *Determination of the Graphite.*—Ten grms. of the ore are dissolved in hydrochloric acid—weeks are needed to effect the solution—and the separated graphite filtered off on an asbestos, filtered, washed, and oxidised with chromic and sulphuric acids to carbon dioxide.—C. A. K.

*Determination of Free Sulphuric Acid in Aluminium Sulphate.* F. Beilstein and T. Grosset. Zeits. Anal. Chem. **29**, 73—78.

ERLENMEYER and Levinstein's method for the determination of the free acid in aluminium sulphate by treating with magnesium ammonium phosphate and titrating the free acid in the filtrate, is only accurate when the double phosphate is freshly prepared. When the magnesium ammonium phosphate has been kept for some time (even under water) it loses ammonia, and further, boiling is necessary to effect complete decomposition between the aluminium sulphate and the phosphate, and here a further loss of ammonia occurs. A review of other methods for the determination of the free acid in the presence of neutral or of acid salts follows. The authors consider that the methods dependent on the insolubility of sulphates in alcohol and on the direct titration with alkali employing one of the tropaeolin colours as indicator, are inaccurate, and are qualitative rather than quantitative tests. The following method is recommended as the most reliable:—Dissolve 1—2 grms. of the substance according to its richness in free acid, in 5 cc. of water, add 5 cc. of a cold saturated neutral solution of ammonium sulphate, allow to stand for a quarter of an hour with repeated shaking, and precipitate with 50 cc. of 95 per cent. alcohol. Filter, wash with 50 cc. of 95 per cent. alcohol, evaporate the filtrate on the water-bath, dissolve the residue in water, and titrate with decinormal caustic potash, using litmus as indicator. All the neutral aluminium sulphate is thus thrown down as ammonium alum, and the whole of the free acid remains in solution. Only a little ammonium sulphate is dissolved by the alcohol. For technical purposes the results are sufficiently accurate; the mean error of six test analyses amounts to about 0.15 per cent. The samples contained from 1.27 per cent. to 5.89 per cent. of free sulphuric acid.—C. A. K.

*Valuation of Roofing Slates.* H. Brunner. Schweiz. Wochenschr. f. Pharm. 1889.

See under IX., page 393.

*The Examination of Roofing Slates.* F. Reverdin and C. de la Harpe. Chem. Zeit. 14, 64—65, 94—95, and 126—127.

See under IX., page 394.

*The Valuation of Fuming Sulphuric Acid.* B. Setlik. Chem. Zeit. 13, 1670.

INSTEAD of the usual method of determining the sulphuric anhydride present by titration with normal caustic soda solution, the author proposes to titrate with water until the acid ceases to give off fumes of anhydride. 100 grms. of the fuming acid are weighed into a 200 cc. flask, and water is slowly dropped in from a burette whilst the flask is kept cool. At first a thick cloud is formed over the liquid on the addition of each drop, but as the composition of the liquid approaches that of the monohydrated acid, the fumes become less apparent, and the flask must then be shaken after each addition of water until the fumes have become completely absorbed. The point when a further drop of water causes no fuming is thus easily seen, and several results are quoted to attest the correctness of the method, which is very suitable for use in the factory.

—G. H. B.

*The Examination of Zinc Ores.* W. Minor. Chem. Zeit. 13, 1670.

THE article refers to the difficulty of discriminating between the amounts of zinc present as carbonate, silicate and sulphide. According to one method the carbonate and silicate may be extracted by boiling the finely powdered ore several times with strong ammonia, but the silicate is not satisfactorily reduced. The author recommends the following procedure. The total zinc is first determined by treatment with strong hydrochloric acid in the usual way. A second portion is carefully exhausted with boiling dilute caustic soda, which completely dissolves the carbonate and silicate of zinc, leaving the sulphide untouched. A third portion is boiled for 15 minutes with acetic acid of 50 per cent. strength, which dissolves only the carbonate of zinc. The author has proved the accuracy of this method of separation from the results of numerous concordant analyses.

—G. H. B.

*Estimation of the Cadmium in the Products of Zinc Manufacture.* W. Minor. Chem. Zeit. 14, 4.

IN order to avoid the fourfold precipitation with sulphuretted hydrogen (see this Journal, 1890, 109) the author suggests the following alternative method:—A known quantity of the substance is dissolved as usual in hydrochloric acid, and the cadmium and iron separated by precipitation with sulphuretted hydrogen. The precipitate of cadmium sulphide, which always contains zinc sulphide, is washed with hot water, dissolved in hydrochloric acid and filtered. The solution is heated to boiling and an excess of boiling, dilute caustic soda added; the cadmium hydroxide which separates is filtered off and repeatedly washed with 1 per cent. caustic soda, then with hot water, till no longer alkaline. The filter containing the precipitate is then transferred to a Rose's crucible, and the water driven off by gentle warming, after which the crucible is heated to redness while a stream of oxygen is passed into it. From the weight of cadmium oxide so obtained the amount of cadmium present in the sample can be readily found.

In the determination of the cadmium in the so-called "pure cadmium" of the zinc works, the precipitation by sulphuretted hydrogen may be omitted, as this product contains only a small trace of iron which does not influence the determination.—O. H.

*Estimation of Cadmium in Calamine.* W. Minor. Chem. Zeit. 14, 34.

THE amount of cadmium in calamine is generally not taken into account in estimating the zinc, but is determined with

it, in the ammoniacal solution obtained after the precipitation of the iron. As the cadmium is a very valuable by-product, it is suggested that it should be determined separately. The following method is proposed:—The ammoniacal filtrate containing zinc and cadmium is made slightly acid with hydrochloric acid and the hot solution poured into an excess of hot aqueous soda. The insoluble cadmium hydroxide is determined as oxide (see preceding abstract). The zinc is determined in the filtrate, after neutralising most of the excess of soda with hydrochloric acid, by titration with sodium sulphide.—N. H. J. M.

*Estimation of Nitrogen by Schultze-Tiemann's (Schlössing's) Method.* F. Coehius and T. Moeller. Chem. Zeit. 14, 33.

THIS method has been found, especially by those who have to do with explosives, to give too low results; control analyses made with pure potassium nitrate gave, as a rule, 13.6 per cent. of nitrogen (instead of 13.86), the results often being as low as 13.5 or 13.3 per cent. Long experience in analysing gun-cotton by the method, showed that the concentration of the reagents is of great importance, and that the amount of substance used should be suited to the size of the apparatus. The following were employed by the authors:—A long-necked flask of 350 cc. capacity, a measuring tube of 150 cc. capacity, a ferrous chloride solution (70 grms. of salt to 100 cc. of water), hydrochloric acid (about 37 per cent.). The amounts taken were:—Pure saltpetre, 0.3—0.4 gm.; ferrous chloride solution, 5—15 cc., with twice the amount of acid. When 25 to 50 cc. of water were used, the results varied between 13.76 and 13.86 (mean, 13.81) per cent. of nitrogen, and the experiment took 30 to 40 minutes. With 80 to 150 cc., percentages of 13.39 to 13.05 were obtained (mean, 13.21), the analyses took from 70 to 90 minutes.—N. H. J. M.

*On the Volumetric Determination of Nitric Acid by a Solution of Diphenylamine in Sulphuric Acid.* J. A. Muller. Bull. Soc. Chim. 1889, 670.

THIS method may only be used in the absence of other oxidising substances, as these would also give a colouration with a solution of diphenylamine in sulphuric acid. A small quantity of hydrochloric acid does not interfere, but the colour is altered and destroyed by hydrobromic and hydriodic acids. Spiegel, to whom the process is due, states that organic substances do not influence the colouration, but the author found that a few drops of a 7.5 per cent. solution of dextrin altered the colour materially.

To make an estimation, 5 cc. of a solution containing 0.2 gm. of diphenylamine in 1 litre of concentrated sulphuric acid are placed in a test tube and 1 cc. of the nitrate solution added; similar solutions are made containing a known quantity of nitric acid, and the colours, after standing one hour, compared. If care be taken to prepare all the tubes in exactly the same way, and the nitrate solution contain from 1—5 mgrms. of  $\text{N}_2\text{O}_5$  per litre, results may be obtained to within 0.5—1 mgrm. of  $\text{N}_2\text{O}_5$  per litre.

If any other oxides of nitrogen be present they must be oxidised by permanganate. Provided the solutions be colourless, this method may be applied to the determination of nitrates in soils and drainage waters.—A. L. S.

*Some Applications of Caustic Soda or Potash and Carbon to the Qualitative and Quantitative Analysis of Minerals.* C. A. Burghardt. Lit. and Phil. Soc. Manchester, March 4, 1890.

AFTER many experiments, the author found that in the analysis of all refractory silicates, several refractory oxides and compounds of oxides, and some other insoluble mineral compounds, the best results were obtained by mixing the finely divided mineral with about 10 per cent. of its weight of finely divided charcoal, and projecting the mixture carefully into a silver crucible containing fused caustic soda or potash in the proportion of six times the weight of the mineral powder taken for analysis. The crucible and its

contents were then carefully heated over an ordinary Bunsen's burner until the reaction arising is complete. This point is easily ascertained by the fact that all further evolution of combustible gas has ceased, and the mass in the crucible has become dry and generally white or grey in colour.

From the experiments made, the author believes that hydrogen gas is evolved from the caustic alkali, and possibly a small quantity of carbon monoxide, whilst undoubtedly carbon dioxide is largely produced by the combination of the carbon with the oxygen of the caustic alkali and the oxygen of the oxides present in the minerals taken for analysis. The author believes that during the course of the reaction, metallic sodium or potassium is liberated, and that these metals whilst in *statu nascenti* combine either with the metallic oxide (as in the case of the oxides of zinc and tin) or with the acid present in the mineral.

The details of some experimental trials of the process are next given.

*Tin-Ore from Cornwall.*—Two samples of roasted "Black tin" were reduced to an exceeding fine powder and submitted to Bughardt's process. ("Black tin" is the tin ore which has been concentrated by washing away the lighter mineral impurities, drying and afterwards roasting to secure freedom from sulphur, arsenic and antimony.) For the analysis, 0.5 grm. of the mineral was taken, and the heating in the silver crucible with the caustic alkali only took place over the ordinary Bunsen lamp for 30 minutes. Lixivation with water, followed by a second fusion of the residue, was sufficient to bring the mineral into a complete state of resolution.

*Wolframite* (principally tungstate of iron).—This is a difficult mineral to analyse by the older methods and much time is expended.

By the author's process the iron is entirely separated from the tungstic acid *at once*, and remains behind on the filter after solution of the melt and subsequent filtration, as ferric oxide and magnetic oxide.

*Chrome Iron Ore* was treated with caustic soda with an addition of ammonium nitrate to ensure full oxidation of chromic oxide to chromic anhydride. Heating for half an hour over the ordinary Bunsen lamp proved sufficient. Other minerals which proved amenable to the caustic soda treatment as described, were Rutile, Barytes, Kaolin, Tale, Cyanite, and double silicates like Tourmaline, Hornblende, Garnet. Excellent results have been obtained with Fluorspar and Pitchblende. By this method the costly and troublesome blowpipe and bellows are dispensed with.

#### *Action of Phenols on Honey and on the Substance produced by Evaporating to Dryness spent Sulphite Solutions.* A. Hbl. Chem. Zeit. **14**, 3.

THE author has already (this Journal, 1887, 455) described the action of phenols, in presence of sulphuric and hydrochloric acids, on the carbohydrates. When honey is treated with an aqueous solution of phloroglucinol and much strong hydrochloric acid, the mixture acquires, after some time, a pale red colouration, which becomes more and more distinct. Resorcinol produces, after a long time, a splendid light-red colour. Other phenols react with honey only when heated. Aqueous aniline sulphate solution colours a solution of honey yellow after some time.

When the yellow transparent mass, obtained by carefully evaporating to dryness spent sulphite-lye, is dissolved in water, and heated with aqueous phloroglucinol and strong hydrochloric acid, a violet-red colouration is produced; other phenols give inconsiderable colourations. With concentrated sulphuric acid, the colour reactions are more distinct:—aqueous resorcinol solutions and alcoholic solutions of orcinol, thymol, and cresol, in presence of much strong sulphuric acid, give strong dark red colourations, and an alcoholic solution of  $\alpha$ -naphthol produces a splendid, intense red-violet colour. The same reactions are obtained when the spent sulphite-lye itself is employed.—N. H. J. M.

#### *Coal Oil and Lignin.* A. Hbl. Chem. Zeit. **14**, 34.

THE author previously (this Journal, 1889, 1012) proposed urea and antipyrine as reagents for woody cell-membrane. Coal oil also gives rise to production of colour with lignin. Wood and paper treated with coal oil diluted with alcohol and strong hydrochloric or moderately dilute sulphuric acid acquire an intense red colour, the reaction being strongest when concentrated alcoholic solutions of coal oil are used. The colour reactions are given by all substances which yield coal oil when destructively distilled: for example, albuminoids, horn, wool, &c. It is probable that the colour is due to the action of pyridine bases in the coal oil on cinnamic aldehyde contained in the wood (compare this Journal, 1889, 640).—N. H. J. M.

#### *Tobacco Juice as a Reagent for Lignin.* A. Hbl. Chem. Zeit. **14**, 67.

THE author has described (Chem. Zeit. **14**, 34; see preceding abstract) a colour reaction given by lignin and bone oil in presence of hydrochloric or fairly concentrated sulphuric acid, and considers it due to the presence of pyridine bases present as empyreumatic products in the bone oil. Considering that the nicotine and albuminoids in tobacco might yield similar substances on destructive distillation, he substituted tobacco juice from a reservoir pipe for the bone oil, and found that, when fresh, a fairly intense red colouration was obtained, sufficing even for the detection of wood-cellulose in paper. The colour also appears when cinnamic aldehyde or an alcoholic solution of oil of cinnamon is treated with fresh tobacco juice and concentrated hydrochloric acid. Nicotine itself needs some time for the development of the colouration.—B. B.

#### *Detection of Cotton-Seed Oil in Lard.* A. V. Ashóth. Chem. Zeit. **14**, 93–94.

Muter and de Koningh (Analyst, 1889, 61) have described a method for the detection of cotton-seed oil in lard, an outline description of which is as follows:—The sample is saponified, the fatty acids precipitated as lead salts which are then washed and shaken out with ether; the ethereal solution of such fatty acids as form lead salts soluble in that liquid is decomposed by hydrochloric acid, the two layers of liquid separated, the solution of fatty acids in ether washed, its volume noted, a known quantity taken, and titrated with standard alkali; another portion is run off, the ether evaporated in a stream of carbon dioxide, and the iodine number of the fatty acids left determined.

The author experimented with single samples of pure lard and cotton-seed oil (source not stated), and found for the former 54.31 per cent. of fatty acids with an iodine number of 93.66, and for the latter 69.20 per cent. of fatty acids with an iodine number of 136.69. In both cases the fatty acids are calculated as oleic acid. Mixtures gave results fairly near those demanded by their composition, so that in one containing 50 per cent. of cotton-seed oil was found 48.66 per cent., in another 20.52 instead of 25 per cent., and 5 per cent. in place of 12.8 per cent. in a third. The author views the method as of considerable value.—B. B.

#### *Drying Oils, their Properties, Tests, and Applications.* L. Borucki. Tech. Mittheil. f. Malerei, **6**, No. 74 and 75.

THE author describes the origin, chemical composition, properties, and purification of these oils. He gives the following description of a good drying oil: it should be clear and transparent and should not become turbid either on heating or on long standing (absence of albuminoids, &c.); shaken with water or alcohol it should give no acid reaction, in the first case mineral acids are absent, in the second free fatty acids or resin; there should be no appreciable quantity of ash; treated according to Livache, it should dry in 24 hours, and the varnishes should yield a solid mass in the same time (absence of non-drying oils, resinous oils, and mineral oils). Livache's test is made as follows, 1 grm. of lead powder is prepared by precipitating lead acetate with zinc, washing first with water and then with alcohol and ether and drying in vacuo. This is placed on a watch

glass, weighed and 0.6 gram. of oil dropped on it from a burette so that each drop remains separate from the rest; it is then placed in a light room at the ordinary temperature. A drying oil thus treated ceases to lose weight after 18 hours, a non-drying oil not until six days.—A. L. S.

**Testing Cocaine.** K. Mezger. *Pharm. Zeit.* **34**, 697. To distinguish cocaine from other alkaloids, 0.05 gram. of cocaine hydrochloride is dissolved in 5 cc. of water and five

drops of a 5 per cent. solution of chromic acid added; as each drop is added a distinct precipitate is formed, which dissolves immediately. On then adding 1 cc. of hydrochloric acid (conc.) a dark orange-coloured precipitate of cocaine chromate is formed.

In the following table the behaviour of a number of alkaloids towards chromic acid, chromic acid and hydrochloric acid, and towards potassium chromate is shown. The solutions tested must be neutral.

0.05 Grms. dissolved in 5 cc. of Distilled Water.	I. 5 Drops of a 5 per cent. Solution of Chromic Acid.	II. Addition of 1 cc. of HCl (conc.) to I.	III. 5 drops of a 9.20 Per Cent. Solution of $K_2CrO_4$ .
Cocaine hydrochloride .....	Distinct precipitate with each drop, which then disappears.	Orange yellow, amorphous precipitate.	Clear.
Ecgonine hydrochloride ....	Clear.	Clear.	Clear.
Quinine hydrochloride .....	Yellow precipitate.	Precipitate dissolves; on standing separates again in needle-shaped crystals.	Yellow precipitate.
Quinidine hydrochloride ....	Yellow precipitate.	As with quinine.	Yellow precipitate.
Cinchonidine hydrochloride	Yellow precipitate.	As with quinine.	Turbidity with each drop added; on standing a crystalline precipitate.
Cinchonine hydrochloride ...	Clear.	Clear.	Pale yellow precipitate.
Hydroquinine hydrochloride	Yellow resinous precipitate.	Clear. Crystals separate after long standing.	Yellow precipitate.
Apomorphine hydrochloride	Red-brown precipitate turns green after standing a minute.	Dirty brown precipitate.	Dirty brown precipitate.
Brucine hydrochloride .....	Yellow precipitate.	Orange-yellow precipitate. Solution dark red.	Crystalline precipitate forms gradually.
Strychnine hydrochloride ...	Yellow crystalline precipitate forms after a minute's standing.	Yellow crystalline precipitate.	As with brucine.
Veratrine hydrochloride ....	Yellow precipitate.	Yellow precipitate.	Precipitate forms gradually.

Sparteine and atropine sulphates and the hydrochlorides of caffeine, pilocarpine, and codeine give no reactions with these reagents. Morphine hydrochloride gives a green colouration with all three reagents owing to the reduction of the reagent; narceine gives a crystalline precipitate after long standing with chromic and hydrochloric acids.

—C. A. K.

**Detection of Rosin Oil in Fatty and Mineral Oils.** Hölde. *Mittheil. der könig. tech. Versuchsanstalten*, 1890, 19—22.

THE author finds that in his method for the detection of rosin oil in vegetable or mineral oils (this Journal, 1888, 526), it sometimes happens that the colouration does not readily appear. A continuous and vigorous shaking, however, causes the acid to assume a distinct red colour when rosin oil is present. For detecting the presence of small quantities of rosin oil, he recommends shaking with stronger sulphuric acid of sp. gr. 1.624, whereby (in testing a series of 11 different sorts of rosin oil) he always obtained a distinct red colouration after shaking for a short time. To apply a still stronger acid is not advisable, as it would affect the other oils present. This reaction is not as delicate as that with anhydrous acetic acid and sulphuric acid (this Journal, 1888, 136, 526 and 871; 1889, 572), but being extremely simple the author considers it useful for technical purposes as a preliminary examination. Quantities as small as 1.5 per cent. of rosin oil could in all experiments be detected by this reaction, and mostly even 0.5 and 1.0 per cent. Castor oil is the only exception, its limit being 5 per cent. But in this case, after shaking with the above-named acid, the castor oil itself, and not the acid, assumes a red colour, even if as little as 1 per cent. of rosin oil be present, whilst pure castor oil remains yellowish-white. The author thinks that intentional adulterations of less than 1 per cent. are practically not to be found.

When sulphuric acid of 1.624 sp. gr., after having been shaken with the oil, is of a yellow or yellowish-brown colour, rosin oil is not present in the above-named limits; but if the

acid become red or brown, another portion of the substance should be shaken with double its volume of 86—90 alcohol, to extract rosin oil, if present. This extraction is necessary, because the presence of train oils, earth-nut oil, and mineral oils containing asphalt substances, may give similar colour appearances in the original substance. Castor oil must be treated in the same way, if the acid has changed the colour of the oil to red or brown, which colour may originate from the presence of train oil. The test cannot be applied for those tar-oils which are soluble in alcohol with brown or black colours. The alcoholic extract is then treated with sulphuric acid of 1.624 sp. gr., the presence of rosin oil being shown by a red or violet colouration. This colour is more constant than that obtained by the test with anhydrous acetic acid and sulphuric acid of 1.53 sp. gr., which changes after a few moments. For the detection of smaller quantities of rosin oil, the alcoholic extract is evaporated, then the test with sulphuric acid of 1.624 sp. gr. applied, and a comparative test with anhydrous acetic acid and sulphuric acid of 1.53 sp. gr. made. The author finds, with Morawsky, that anhydrous acetic acid and sulphuric acid of 1.53 sp. gr. produce red-brown colourations in train oil and in earth-nut oil. Therefore, when these substances are present, and rosin oil is to be tested for, an alcohol extraction has to be made prior to the application of the above reagents. The alcoholic extracts of train oil and of earth-nut oil do not show the colourations characteristic for rosin oil.

The author furthermore states that the phosphoric acid test for train oil is uncertain, for on the one hand rosin oils produce red colourations with this acid, and on the other hand distinct colourations only appear when large quantities of train oil are present in other oils. The author mentions that this is contrary to the experience of Schaeidler, who found that even  $\frac{1}{10000}$  of train oil can be detected by the reaction with phosphoric acid. Whether the above reaction with phosphoric acid is characteristic for rosin oils has to be proved. (Compare this Journal, 1890, 112.)—H. S.

*Boessneck* has suggested that a method might possibly be based on the solubility of antimonious oxide in tartaric acid in the proportion of one molecule to two of the acid, and the author has experimented in this direction. He finds, however, that variable quantities of antimonious oxide are dissolved, e.g., 60—66.9 per cent. instead of the theoretical 77.6 per cent., the action appearing to diminish as the proportion of free tartaric acid decreases.—B. B.

*On the Estimation of Glycerol in Crude Glycerin.* F. Filsinger. *Chem. Zeit.* **14**, 197.

To ascertain the amount of glycerol in crude glycerins, the author compares a series of results obtained by Fickert and Hirsch between the modified permanganate method (*Chem. Zeit.* **13**, 127) and Benedikt and Cantor's acetin method as applied by O. Hehner (this Journal, 1889, 6—8). Throughout the series, which consists of crude glycerins of different origin, the acetin method gives higher results than the permanganate method, viz.:—

No.	Permanganate Method.	Acetin Method.
	Per Cent.	Per Cent.
1	70.2	(a) 74.7
	..	(b) 75.4
2	78.5	(a) 80.6
	..	(b) 81.9
3	76.1	(a) 80.6
	..	(b) 80.9
4	72.1	76.8
5	(a) 73.9	(a) 78.4
	(b) 73.3	(b) 78.2
	..	(c) 78.5
6	73.8	78.1
7	70.5	74.9
8	72.1	73.2
9	(a) 77.6	79.5
	(b) 78.0	..
10	(a) 82.2	86.7
	(b) 81.9	..
11	(a) 50.6	(a) 54.8
	(b) 50.4	(b) 53.4
12	(a) 66.3	69.9
	(b) 66.7	..
13	(a) 69.6	76.6
	(b) 70.1	..
14	(a) 74.8	77.4
	(b) 75.2	..
15	(a) 67.1	(a) 73.4
	(b) 66.5	(b) 73.7
	..	(c) 73.8
16	77.2	79.8
17	71.2	(a) 76.7
	..	(b) 77.4

The author was in a position to testify to the correctness of the permanganate method in several instances by the practical yields from the crude materials employed. The results obtained confirm his view that the acetin method gives percentages of glycerol in crude glycerins which are too high, and he states that these results are

contrary to those obtained by Hehner and Lewkowitsch. He objects to Hehner's proposal in analysing crude glycerin to strike an average between the results obtained by the acetin and the bichromate methods, but recommends further examination which might lead to a more correct modification of the acetin method.—H. S.

*Determination of Cellulose.* G. Lange. *Zeits. Physiol. Chem.* **14**, 283.

Ten grms. of the substance in which the cellulose is to be determined are placed in a stoppered retort, together with three or four times its weight of pure caustic potash and 30—40 cc. of water, and the temperature raised to 140° C. by means of an oil-bath. At this point reaction sets in with considerable frothing, and is generally complete after continuing the heating for about an hour at 180° C. After cooling to about 80° C. the contents of the retort are washed into a beaker, acidulated with dilute sulphuric acid, made slightly alkaline with weak caustic soda to dissolve any substance other than cellulose precipitated with it on acidulation, and the purified cellulose filtered off by the aid of a filter pump. By washing with hot and cold water, drying, weighing, and determining the ash retained, the quantity of pure cellulose is arrived at.—B. B.

*Estimation of Quinine in Quinine Tannate.* S. Neumann. *Zeits. Anal. Chem.* **28**, 663—668.

The quinine in tannate of quinine cannot be accurately estimated by Orillard's method, which is recommended by the German Pharmacopœia owing to the fact that the alkaloid cannot be completely extracted with alcohol. The following method can be conveniently employed for the analysis of the tannate:—2 grms. of the finely-divided salt (*Quinimum tannicum*) are decomposed with 20—25 cc. of potash of sp. gr. 1.24, the mixture is then diluted to about 60—80 cc. and shaken vigorously with 100 cc. of pure ether in a well-stoppered bottle, in order to dissolve the liberated quinine. The presence of solid particles in suspension, either in the ethereal or alkaline solution, shows that the sample is impure or that the salt has not been completely decomposed. After some time 50 cc. of the ethereal extract are transferred to a tared beaker by means of a pipette and the solution is allowed to evaporate in a warm place; the residue is then dried at 100° and weighed. The residue should be completely soluble in dilute hydrochloric acid and in dilute sulphuric acid.

Quantitative experiments with sulphate of quinine showed that the author's method gives results which agree well among themselves, but which are generally about 2.5 per cent. too high; this is owing to the fact that the ether is slightly soluble in water and that evaporation takes place during the process.

A number of different samples of commercial tannate of quinine examined by the method described above gave a percentage of quinine more than double that found by Orillard's method.—F. S. K.

*Butter Fat.* S. Bondzynski and H. Ruff. *Zeits. Anal. Chem.* **29**, 1—6.

To determine the easily volatile acids contained in butter fat the authors take advantage of the fact that these are the most readily soluble and carry out the determination as follows:—4—5 grms. of the butter are saponified with 50—60 cc. of semi-normal alcoholic potash, the excess of alkali neutralised by semi-normal hydrochloric acid, and the alcohol evaporated off. The resulting soap is decomposed by an excess of hydrochloric acid, the insoluble fatty acids filtered off, washed with hot water, dissolved in alcohol, and the solution titrated with alcoholic potash. From the difference between the number of cc. of alcoholic potash required by the total fatty acids and the number required by the insoluble acids, the amount required to neutralise the volatile acids is got. This value can be got directly by

dissolving the soap first obtained, after evaporating off the alcohol, in water, and adding the same quantity of semi-normal sulphuric acid as of caustic potash required for the saponification. The insoluble fatty acids are then filtered off and washed, and the volatile acids determined by titration in the filtrate. The two methods are said to yield results agreeing amongst themselves and with those got by the ordinary method of distillation. If the insoluble fatty acids be weighed before titration, the amount of the glycerides is got and the amount of the glycerides of the volatile acids can then be obtained by difference.

The volatile acids are only present in butter as glycerides, and it is only after prolonged keeping that their presence in the free state becomes evident. Samples kept for 6—8 days at a temperature of 25° show no trace of free volatile acid, although the decomposition of the butter is considerably advanced. Butter, when quite fresh, contains some free insoluble acids and also free oleic acid. The turning sour of butter is essentially due to the increase in the quantity of insoluble fatty acids and especially to that of oleic acid. Two samples tested gave when fresh 0.50 per cent. and 0.27 per cent. of insoluble fatty acids, and 0.17 per cent. and 0.16 per cent. of oleic acid; after 20 days' keeping at the ordinary temperature they contained 1.29 per cent. and 3.60 per cent. of the former, and 0.47 per cent. and 0.71 per cent. of the latter respectively.

Phenolphthaleïn is recommended as the indicator to be used in testing for the free acids in preference to litmus, the latter being quite useless in testing for the free oleic acid. The importance of determining the free acid in butter as a means of determining its freshness is pointed out. The method employed is described in detail in the paper.

To determine the quantity of hydroxy acids in fresh butter the authors adopt Benedikt's method (this Journal, 1888, 594). The butter is saponified, the insoluble fatty acids filtered off, and the water in the filtrate removed by repeated filtrations through dry filter paper. The resulting product is then treated with acetic anhydride. An experiment gave 18.2 as the acetyl value for butter.—C. A. K.

*Contributions to the Analysis of Fats.* H. Noerdlinger. Zeits. Anal. Chem. **29**, 6—13.

This is a continuation of previous work on the free fatty acids of fats, oils, &c. (this Journal, 1889, 806). The free fatty acids are determined by extracting the total fats with petroleum ether, and phenolphthaleïn is used as the indicator in the titration with alkali; the results are calculated as oleic acid. In order to judge of the rancidity of fats and oils of commerce by the amount of free acids they contain, it is necessary to know the percentage of free acids in the pure products. The results of experiments in this direction is shown in the following table, both for oils and oil-cakes. The numbers given are the mean values found:—

	100 Parts contain		Per Cent. of Free Fatty Acids on Total Fat.
	Free Fatty Acids.	Total Fats.	
I.—OILS.			
Rape ( <i>Brassica rapa</i> ).....	0.42	37.75	1.10
Cabbage ( <i>Brassica campestris</i> )...	0.32	41.22	0.77
Poppy ( <i>Papaver somniferum</i> )....	3.20	46.90	6.66
Earth-nut ( <i>Arachis hypogæa</i> )— (a.) Seed .....	1.91	46.60	4.15
(b.) Outside pale yellow husk...	1.91	4.13	43.10
Sesame ( <i>Sesamum orientale</i> ) .....	2.21	51.59	4.59
Castor ( <i>Recinus communis</i> ) .....	1.24	46.32	2.52
Palm-nut ( <i>Elaeis guineensis</i> ) (with 6 per cent. husks) .....	4.19	49.16	8.53
Coprah ( <i>Cocos nucifera</i> ) .....	2.98	67.10	4.42

	100 Parts contain		Per Cent. of Free Fatty Acids on Total Fat.
	Free Fatty Acids.	Total Fats.	
II.—CAKES.			
Rape .....	0.93	8.81	10.55
Poppy .....	5.66	9.63	58.89
Earth-nut .....	1.42	7.65	18.62
Sesame .....	6.15	15.44	40.29
Palm-nut .....	1.47	10.39	14.28
Earth-nut meal (extracted).....	1.55	18.68	8.29
Cocoa.....	1.31	13.11	10.51
Linseed.....	0.75	8.81	9.75
Castor .....	1.27	6.53	20.07

The oils obtained by pressing only contain a portion of the free fatty acids. The so-called "technical oils" which result from a second and third pressing of the seeds also contain free fatty acids, but the greater portion thereof remains behind in the cakes.

In the case of "extracted oils," as opposed to oils obtained by pressing, it is pointed out that the composition of the fat extracted is the same as that left behind in the seeds (*i.e.*, both contain the same percentage of free acids), since both glycerides and fats are equally dissolved by the solvents. The test for free acids, together with a microscopical examination, serves therefore to distinguish "extracted" from "pressed" meal; and further, by testing the oils also for free acid "extracted" and "pressed" oils can be distinguished. This holds as long as the product is unadulterated. A number of analyses of palm-nut cake and of cocoa-nut cake are given which bear out this point.

—C. A. K.

*Cassia Oil and its Adulteration.* Schimmel and Co. Zeits. Anal. Chem. **29**, 93—94.

CASSIA oil is adulterated with colophonium and other substances, in China. To examine the oil, 50 grms. are fractionated and the distillation continued up to 280°—290°. The main bulk of the oil distils over between 240° and 260°. The residue in the fractionating flask is weighed; if it solidify on cooling the oil is adulterated; pure cassia oil also leaves a residue, but this remains liquid on cooling. Gilbert (Chem. Zeit. **13**, 1406) has shown that cassia oil adulterated with colophonium satisfies the requirements of the Pharmacopœia, and considers that the determination of the acid equivalent lends the best aid to the detection of the adulterant. Two grms. of the oil are dissolved in 30 cc. of alcohol, and titrated with alcoholic potash, using phenolphthaleïn as indicator; 1 gm. of the pure oil requires from 10—13 mgrms. of the alkali, whilst a sample containing 20 per cent. of colophonium needs 40 mgrms., and colophonium itself (sp. gr. 1.08) 150 mgrms.

Schimmel and Co. value cassia oil by a determination of the cinnamyl aldehyde contained. This is arrived at by difference, the sample being treated with acid sodium sulphite and the uncombined portion of the oil weighed. No details of the method are given. It is considered that a sample of the oil with less than 75 per cent. of aldehyde is suspicious, and with less than 70 per cent. adulterated. The chief constituent of cassia oil beyond cinnamyl aldehyde is cinnamyl-acetic ether— $\text{CH}_3\text{CO.O.C}_9\text{H}_9$ .—C. A. K.

*The Incompatibility of Codeine and Morphine Sulphate.* Claassen. N.Y. Pharm. Rund. 1890, 40.

THE author points out that codeine is capable of decomposing morphine sulphate as well as morphine salts generally with separation of morphine which is insoluble in water. This

reaction is sufficiently complete to admit of its application to the estimation of the amount of codeine present in a liquid. For this purpose an excess of morphine sulphate is added to the warmed liquid with frequent shaking, and after cooling the mixture is allowed to stand for 48 hours and the separated morphine is collected on a tared filter. If after addition of more morphine sulphate to the liquid no further deposition takes place in 24 hours, the weight of the morphine obtained multiplied by 0.9868 gives the amount of anhydrous codeine, or multiplied by 1.0462, the amount of codeine crystallised with one molecule of water. Thus, 100 parts of anhydrous codeine decomposes 126.76 parts of morphine sulphate. In cases where codeine salts or morphine or morphine salts may be present, excess of magnesia is added and the mixture evaporated to dryness. The residue is now stirred up with some water, shaken several times with ether free from alcohol, the ether distilled off and the residue exhausted with hot water. The codeine in the resulting solution can then be determined as above specified.—O. H.

#### PATENT.

*A Process and Apparatus for Freeing Wool from Grease.* L. Pinagel, Aachen, Germany. Eng. Pat. 20,936, December 31, 1889. 8d.

See under V., page 386.

### New Books.

DIE CHEMIE DES STEINKOHLENTHEERS MIT BESONDERER BERÜCKSICHTIGUNG DER KÜNSTLICHEN ORGANISCHEN FARBSTOFFE, VON DR. GUSTAV SCHULTZ. Zweite vollständig umgearbeitete Auflage. Zweiter Band. Die Farbstoffe. Siebente (Schluss-) Lieferung. Braunschweig: Friedrich Vieweg und Sohn. London: H. Grevel and Co., 33, King Street, Covent Garden. 1890.

THIS, the concluding part of the whole work, commences on page 1153, and from this page to page 1267 we have an Appendix continued from the preceding part and concluded. Thus ends the Appendix devoted to the newest patented discoveries and inventions in Coal Tar products and Colours. On page 1268 commences a scheme of analysis for the Artificial Organic Colouring Matters, which ends on page 1275.

From page 1276 to page 1354 extends a comprehensive index of German patents taken out on Coal Tar preparations, and arranged in tabular form under the following headings:—No. of the German Patent. Date. Applicant and Holder of the Patent. Title of the Patent. Class. Remarks. The work terminates with a copious and complete Alphabetical Index for the entire work.

A POCKET-BOOK FOR PHARMACISTS, MEDICAL PRACTITIONERS, STUDENTS, &c., &c. (British, Colonial, and American.) By THOMAS BAYLEY, Assoc. Roy. College of Science, Consulting Chemist, Analyst, and Assayer. London: E. and F. N. Spon, 125, Strand. New York: 12, Cortlandt Street. 1889.

THIS little work is arranged as a pocket-book, is bound in limp morocco leather and gilt, price 6s. On the inside of cover is an Almanack, which is followed by 13 pages of blue-lined blank paper for memoranda or notes. Then come the Title-Page, Preface, and 523 pages of Subject-Matter,

Tables, &c., Alphabetical Index, and nine pages of blank blue-lined paper for notes. The nature of the contents will be gathered from the following synopsis:—

Notes on Materia Medica; Notes on Ordinary Food Materials, Condiments, &c.; Galenical Preparations. Official Drugs, arranged according to Botanical System. Glossary of Botanical Terms. List of Latin Terms and Technical Phrases, &c. Glossary of Medical Terms. Antidote Bag. Poisoning, Domestic Treatment, Symptoms and Treatment. Posological Table. Boiling Points of Liquids. Melting Points of Official Substances. Specific Gravity of Liquids, &c. Solubility of Medicinal Substances.

ANALYSIS:—Testing for Official Substances, Animal Secretions, Calculi, Urine, &c., Alkaloids, Table of A.S. Volumetric Test Solutions of B.P. Behaviour with Indicators. Alkaloids, Properties, and Reactions. Atomic Weights of Elements. Weights and Measures. The Text closes with a selection of Useful Recipes. The little work closes with an Alphabetical Index.

A HANDBOOK FOR SUGAR MANUFACTURERS AND THEIR CHEMISTS. Containing Practical Instruction in Sugar-house Control, the Diffusion process, Selected Methods of Analysis, Reference Tables, &c. By GUILFORD L. SPENCER, A.C., of the U.S. Department of Agriculture. New York: John Wiley and Sons, 15, Astor Place. London: Kegan Paul, Trench, Trubner and Co., Limited. 1889.

SMALL 8vo. volume in Pocket-book form, bound in morocco leather, price 10s. It contains Preface, 117 pages of Subject-Matter, an Alphabetical Index, and concludes with 93 pages of ruled and headed, "Blank Forms for Practical use in Sugar-house Work," and 20 pages of blue-lined blank sheets for memoranda. The text of the 117 pages of Subject-Matter is entitled, "Chemical Control of Sugar-house Work," and it is paraphrased as follows:—1. Measurements. 2. Measurement of the Juice. 3. Measurement of the Juice in the Clarifiers. 4. Automatic Measurement of the Juice. 5. Automatic Determination of the Density of the Juice. 6. The Weight of the Juice, Automatic Determination. 7. Measurement of the Syrup. 8. Weight of the Syrup. Automatic Scale. 9. Masseccutes. Measurement and Weight. 10. Commercial Masseccute. 11. Sugar Weights. 12. Diffusion Work. Measurement of the Juice. 13. Diffusion Work. Automatic Registration of the Amount of Juice Drawn. Then follow:—Chemical Control. Estimation of Losses. Diffusion. Estimation of Cane-Sugar by the Optical Method. Estimation of Cane Sugar by Fehling's Method. General Analytical Work. Available Sugar. Examination of the Bone-Black. Examination of the Quality of the Water Supply and Remedies for Impure Water. Special Reagents. After this, from page 61 to page 117, follow a series of useful Tables and Tabulated Data.

With the text are interspersed 10 engraved illustrations.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

#### SWITZERLAND.

##### Classification of Articles in Customs Tariff.

Note.—Quintal = 220·4 lb. avoirdupois. Franc =  $9\frac{4}{10}$ d.

The following decisions affecting the classification of articles in the Swiss Customs tariff were given by the Swiss Customs authorities in the month of January last:—

Tobacco extract.—Category 9. Duty, 10 francs per quintal.

So-called "sulfonal."—Category 9a. Duty, 7 francs per quintal.

Chromate of chrome.—Category 16. Duty, 30 centimes per quintal.

#### AUSTRIA-HUNGARY.

##### Customs Regulations concerning Creoline and Preparations of Creoline.

The *Moniteur Belge* for the 1st March says that the Austro-Hungarian Customs authorities have recently laid down the following Customs régime for imports of creoline, creoline soap, and pharmaceutical preparations of a base of creoline:—

Solutions of soap in coal-tar oil (naphthalene oil) contained in casks or other receptacles are liable to an import duty of 10 fl. per 100 kilos., conformably to Art. 331 of the tariff.

However, when in any way whatsoever these products, according to their inscriptions, labels, wrappers, &c., appear as medicaments, they will be treated according to Art. 336 of the tariff, which provides for a duty of 24 fl. per 100 kilos., and the sanitary restrictions relative to the source of origin of compounded medicines must be observed.

Creoline soap (soap for destroying parasites in animals, &c.) is liable to the same duty as fancy soap, namely, 15 fl. per 100 kilos., Art. 342b of the tariff, whilst in conformity with the general dispositions, Arts. 336 and 337 of the tariff do not apply. However, in the latter case, the restrictive sanitary measures will be dispensed with.

Pharmaceutical preparations made from creoline (pills, capsules, &c.) are subject, both as regards Customs treatment and the restrictive sanitary measures of their free traffic, to the regulations in force concerning medicines.

#### NICARAGUA.

##### Tallow for Soap Manufacture.

According to the *Moniteur Belge*, the Government of the Republic of Nicaragua has just published a decree declaring free of import duty tallow imported as the raw material used in the manufacture of soap; but the manufacturing importer who sells the tallow free of duty, in virtue of this decree or of former regulations, will incur a fine equal to the value of the quantity sold; and in case of repetition he will be doubly fined, and his authority to further import this article withdrawn.

#### CUSTOMS TARIFF OF MAURITIUS.

Note.—Kilog. = 2·204 lb. avoird. Hectol. = 100 litres = 22 Imp. gallons.

The following is a statement of rates of import duty now levied in the colony of Mauritius:—

Classification of Articles.	Rates of Duty now leviable.
Animal charcoal.....	Rs. Cts. 1,000 kilos. 0·25
Charcoal.....	100 kilos. 0·10
Lime.....	" 0·20
Matches, each box not containing more than 100 matches.....	Gross 0·75
Opium: crude.....	Kilo. 20·00
" refined.....	" 10·00
Manure of all sorts; and the following substances when imported for the purpose of being used in the preparation of manures or other colonial produce, or as disinfectants, viz.: Ammoniacal liquor.....	
Bones, bone-dust, bone-oil, and dissolved bones.....	
Carbolic acid.....	
Chloride of lime.....	
Chloride of manganese.....	
Chloride of soda, solution of soda.....	
Chloride of zinc.....	
Coal and wood soot.....	
Dried muscular flesh and dried blood...	
Ether.....	
Fish and other substances damaged and condemned by the Customs sanitary officers as fit for manure only.....	1,000 kilos. 0·25
Lime, carbonate of lime, sulphate of lime or gypsum, phosphate and superphosphate of lime.....	
Nitrates, silicates, and carbonates of potash and soda.....	
Percchloride of iron.....	
Permanganate of potash.....	
Phosphate of soda.....	
Sulphate of iron.....	
Sulphate and muriate of ammonia and other ammoniacal salts.....	
Sulphate of potash.....	
Sulphate of zinc.....	
Sulphuric acid.....	
Urate and sulphuretted urine.....	
All goods, wares, and merchandise not otherwise charged with duty, and not mentioned above, or not specially exempted, shall be liable to a duty of.....	7½ % ad val.

#### THE AMERICAN TARIFF BILL.

The *Oil, Paint, and Drug Reporter* publishes the full text of the drug section of the Tariff Bill adopted by the Ways and Means Committee of the American House of Representatives. The trouble in the States is that, in spite of the fact that their tariff is higher than that of almost any other nation, the imports continue to increase, and the financial condition of the country is such that it has become

imperative to reduce the revenue. Although the Democratic party, who proposed to adopt legislation in a direction towards free trade, were defeated at the last Presidential election, the anomalies of the existing tariff are so manifest that even the present Republican and Protectionist Government have found it necessary to produce a Tariff Reform Bill of some kind. In this measure they propose, along with a reduction of certain duties, the imposition of an advance in others; but, so far as can be judged at present, the chance that the Bill evolved from the deliberations of the Committee of the House of Representatives will be passed into law is exceedingly slight. The principal alterations proposed affecting the drug trade are that acetic acid is to be reduced from  $7\frac{1}{2}$  cents to 6 cents per pound according to its specific gravity, while the duty on ammonia is changed from an *ad valorem* to a specific rate. The duties on refined camphor are reduced from 5 cents to 4 cents per pound, on chloroform from 50 cents to 40 cents per pound, on raw glycerin from 2 cents to 1 cent per pound, and on refined glycerin from 5 cents to  $4\frac{1}{2}$  cents per pound; on morphia and morphia salts from 1.00 dols. to 50 cents per ounce, on castor oil from 80 cents to 50 cents per gallon, on castor beans from 50 cents to 32 cents per bushel of 50 lb., on ultramarine blue from 5 cents to  $4\frac{1}{2}$  cents per pound, and on varnishes from 40 to 35 per cent. *ad valorem* (with 1.32 dols. per gallon additional duty for every gallon of alcohol contained in them); on acetate of lead from 6 cents to 3 cents for white and from 4 cents to 2 cents per pound for brown; on bicarbonate of soda from  $1\frac{1}{2}$  cents to 1 cent per pound; on refined roll sulphur from 10 dols. to 8 dols., and on flowers from 20 dols. to 10 dols. per ton; and on hops from 22 cents to 15 cents per pound. On the other hand, it is proposed to increase the duty on linseed oil from 25 cents to 30 cents per gallon, that on linseed, poppy-seed, and other oil seeds from 20 cents to 30 cents per bushel, and on window glass by about 10 per cent. The duty on drugs not specified is maintained at 10 per cent. *ad valorem*, on alcoholic perfumes at 50 per cent. *ad valorem* plus 2 dols. per gallon, on liquid preparations of opium at 40 per cent., on unspecified alcoholic medicinal preparations at 50 cents per pound; on all other medicinal preparations, alkaloids, and essential oils at 25 per cent.; on toilet soaps at 15 cents per pound and other soaps 20 per cent. *ad valorem*. It is not proposed to revive the duty on quinine.

#### THE TARIFF BILL.

The following is the text of the clauses in the bill prepared by the Ways and Means Committee affecting "miscellaneous metals and manufactures of" under Schedule C.

Aluminium or aluminium manufactured or in crude form or contained in alloys in which aluminium is the component material of chief value, 35 per cent. *ad valorem*.

Antimony, as regulus or metal, three-fourths of one cent per pound.

Argentine, albata, or German silver unmanufactured, 25 per cent. *ad valorem*.

Brass, in bars or pigs, old brass, clippings from brass or Dutch metal, and old sheathing, or yellow metal, fit only for remanufacture,  $1\frac{1}{2}$  cents per pound.

Bronze powder, 15 cents per pound; bronze or Dutch metal, or aluminium, in leaf, 10 cents per package of 100 leaves.

#### Copper.

Copper imported in the form of ores,  $1\frac{1}{2}$  cents per pound on each pound of fine copper contained therein.

Old copper, fit only for remanufacture, clippings from new copper, and all composition metal of which copper is a component material of chief value, not specially enumerated or provided for in this Act,  $1\frac{1}{2}$  cents per pound.

Regulus of copper and black or coarse copper, and copper cement,  $1\frac{1}{2}$  cents per pound on each pound of fine copper contained therein.

Copper in plates, bars, ingots, Chili or other pigs, and in other forms, not manufactured, not specially enumerated or provided for in this Act, 2 cents per pound.

■ Copper in rolled plates, called braziers' copper, sheets, rods, pipes, and copper bottoms, also sheathing or yellow

metal of which copper is not the component material of chief value, and not composed wholly or in part of iron ungalvanised, 35 per cent. *ad valorem*.

#### Gold and Silver.

Bouillons, or cannetille, metal thread, file or gespinst, and epaulettes, galloons, laces, knots, stars, tassels and wings of gold, silver, or other metals, 35 per cent. *ad valorem*.

Gold leaf, 2 dols. per package of 500 leaves.

Silver leaf, 75 cents per package of 500 leaves.

#### Lead.

Lead ore and lead dross,  $1\frac{1}{2}$  cents per pound; *provided*, that silver ore containing lead shall pay a duty of  $1\frac{1}{2}$  cents per pound on the lead contained therein, according to sample and assay at the port of entry.

Lead in pigs and bars, glaziers' lead, lead wire, molten and old refuse lead run into blocks and bars, and old scrap-lead fit only to be remanufactured, 2 cents per pound.

Lead in sheets, pipes, or shot,  $2\frac{1}{2}$  cents per pound.

Metallic mineral substances in a crude state and metals unwrought, not specially provided for in this Act, 20 per cent. *ad valorem*; mica, 35 per cent. *ad valorem*.

#### Nickel.

Nickel in ore, 2 cents per pound for the nickel contained therein.

Nickel in matte, or other crude form not ready for consumption in the arts, 5 cents per pound on the nickel contained therein.

Nickel, nickel oxide, alloy of any kind in which nickel is the component material of chief value, 15 cents per pound.

Quicksilver, 6 cents per pound; flasks, bottles, or other vessels in which quicksilver is imported shall be subject to the same rate of duty as they would be subjected to if imported empty.

Type-metal,  $1\frac{1}{2}$  cents per pound for the lead contained therein; new types, 25 per cent. *ad valorem*.

#### Zinc or Spelter.

Zinc in blocks or pigs,  $1\frac{3}{4}$  cents per pound.

Zinc in sheets,  $2\frac{1}{2}$  cents per pound.

Zinc, old and worn out, fit only to be remanufactured,  $1\frac{1}{4}$  cents per pound.

#### Miscellaneous.

Manufactures, articles, or wares not specially provided for in this Act, composed wholly or in part of iron, steel, lead, nickel, pewter, copper, tin, zinc, gold, silver, platinum, or any other metal, and whether partly or wholly manufactured, 45 per cent. *ad valorem*.

The most important changes under this head are therefore:—

Aluminium, hitherto free; proposed rate, 35 per cent. *ad valorem*.

Antimony as regulus.—Present rate, 10 per cent. *ad valorem*; proposed rate,  $\frac{3}{4}$  cent per pound.

Copper ore, &c.—Present rate,  $2\frac{1}{2}$  cents per pound; proposed rate,  $1\frac{1}{4}$  cents per pound.

Regulus of copper.—Present rate,  $3\frac{1}{2}$  cents per pound; proposed rate,  $1\frac{3}{4}$  cents per pound copper contained therein.

Copper in rolled plates.—Present rate, 35 per cent. *ad valorem*; proposed rate, 2 cents per pound.

Lead in sheets, &c.—Present rate, 3 cents per pound; proposed rate,  $2\frac{1}{2}$  cents per pound.

Metallic mineral substances.—Present rate, 20 per cent. *ad valorem*; proposed rate, 25 per cent. *ad valorem*. Mica, 35 per cent. *ad valorem*; at present free.

Nickel ore, &c.—Present rate, 15 cents per pound; proposed rate, 2 cents per pound for nickel contained.

Nickel in matte, &c.—Present rate, 15 cents per pound; proposed rate, 5 cents per pound for nickel contained.

Quicksilver.—Present rate, 10 per cent. *ad valorem*; proposed rate, 6 cents per pound.

Zinc or spelter.—Present rate,  $1\frac{1}{2}$  cents per pound; proposed rate,  $1\frac{1}{2}$  cents per pound.

Zinc in sheets.—Present rate,  $2\frac{1}{2}$  cents per pound; proposed rate,  $2\frac{1}{2}$  cents per pound.

Zinc, old and worn.—Present rate,  $1\frac{1}{2}$  cents per pound; proposed rate,  $1\frac{1}{4}$  cents per pound.

The other alterations of interest to our readers are those of the different classes of acids, &c., as follows:—

Acids.—Present rate, 2 cents per pound; proposed rate,  $1\frac{1}{2}$  cents per pound.

Acids.—Present rate, 10 cents per pound; proposed rate, 4 cents per pound.

Acids.—Present rate, 4 cents and 5 cents per pound; proposed rate, 5 cents per pound.

Acids.—Present rate, 15 per cent. *ad valorem*; proposed rate, 6 cents per pound.

Blue vitriol, &c.—Present rate, 3 cents per pound; proposed rate, 2 cents per pound.

Zinc oxide, &c.—Present rate,  $1\frac{1}{4}$  cents and  $1\frac{3}{4}$  cents per pound; proposed rate,  $1\frac{3}{4}$  cents per pound.

Sulphate soda.—Present rate, 20 per cent. *ad valorem*; proposed rate,  $\frac{1}{10}$  cent per pound.

Sulphur.—Present rate, 10 dols. per ton and 20 dols. per ton; proposed rate, 8 dols. per ton and 10 dols. per ton.

Sulphur, refined.—Present rate,  $\frac{3}{10}$  cent per pound, proposed rate,  $\frac{1}{2}$  cent. per pound.

Fire-brick.—Present rate, 20 per cent. *ad valorem*; proposed rate, 1.25 dols. per ton.

Cement, Roman, Portland and hydraulic.—Present rate, 20 per cent; proposed rate, 8 cents per 100 pounds.

Lime.—Present rate, 10 per cent.; proposed rate, 6 cents per 100 pounds.

Plaster of Paris, ground.—Present rate, 20 per cent., 1 dol. per ton; calcined, proposed rate, 20 per cent., 1.75 dols.—*Eng. and Min. Journal, N.Y.*

#### THE INCREASED DUTY ON SPIRITS.

Subjoined is the actual text of Mr. Goschen's proposals in regard to the increased duty upon spirits:—

That, in addition to the duty of Excise payable under the Act of the twenty-third and twenty-fourth years of Her Majesty's reign, chapter 129, for and upon every gallon computed at proof of spirits distilled in the United Kingdom, there shall be charged and paid the duty of sixpence, and so in proportion for any less quantity.

That, in addition to the duties of Customs payable on spirits under the Customs and Inland Revenue Act, 1881, there shall be charged and paid the duties following, that is to say:—

	£	s.	d.
For every gallon computed at proof of spirits of any description as in the said Act mentioned (except perfumed spirits) .....	0	0	6
For every gallon of perfumed spirits .....	0	0	9
For every gallon of liqueurs, cordials, and other preparations entered so as to be chargeable under the said Act with the duty of 1s. ....	0	0	8

And so in proportion for any less quantity.

And the duties of Customs on the articles herein-after mentioned, being articles of which spirits are a part or ingredient, shall be proportionately increased, and shall be as follows:—

	£	s.	d.
Chloroform, the pound .....	0	3	1
Collodion, the gallon .....	1	5	0
Ether acetic, the pound .....	0	1	10
Ether butyric, the gallon .....	0	15	8
Ether sulphuric, the gallon .....	1	6	2
Ethyl iodide of, the gallon .....	0	13	7

And so in proportion for any less quantity.

#### EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

##### MEXICO.

##### Drugs for Guadalajara.

The greater part of the drugs consumed in this important Mexican State are purchased from Germany, England, France, and the United States, although at present a few factories of pharmaceutical chemicals exist in Mexico, which turn out certain articles, principally acids. The largest pharmacists in Guadalajara also manufacture themselves numerous articles; for instance, nitrate of silver and gold salts, as well as a large variety of patent medicines and extracts. In the manufacture of the latter the native sugar-cane alcohol, testing 70°, is employed. Most of the leading pharmaceutical articles are obtained from Germany, and these include glassware, chemical balances, and other apparatus, antiseptic bandages, painters' brushes, coal-tar soap, salicylic acid and salicylate of soda, quinine, cocaine, camphor, borax, pepsine, iodides, opium preparations, caffeine, and vaseline. Essential oils come from Germany, but perfumeries mostly from France and the United States. The United States also supply india-rubber goods, fluid extracts, patent medicines, gelatin capsules and pills, Florida water, liquid paints and varnishes, and sulphuric acid, the latter in competition with that made in Mexico. They also furnish complete fittings for pharmacies. From England come heavy chemicals, quinine, and chloroform, the better classes of india-rubber goods, Windsor soap, scents, and surgical instruments. From France are received patent medicines, fine glassware, bandages, surgical and optical instruments, medicinal wines, quinine, Lourdes water, and many patent medicines and perfumes. — *Chemist and Druggist.*

#### MISCELLANEOUS TRADE NOTICES.

##### THE PRODUCTION OF ALFA IN ALGERIA.

The *Journal Officiel* for the 24th February has an article upon Algeria, in which the following passages, having reference to the uses and production of alfa, occur:—

Alfa, from time immemorial, has been utilised for its fibres. At the present day, alfa is employed in various ways. It is used for cordage and basket-ware; mats, brooms, shoes, &c. are made from it, or again, cords, thick carpets, as also hangings and curtains; the purified fibres can be converted into celluloid; there is obtained from it an excellent pulp for paper making, which is used pure or mixed with the pulp of rags, wood, or straw. It is well known that paper makers, finding a difficulty in obtaining the quantity of rags necessary for an increasingly large manufacture, have had recourse to a large number of vegetable fibres, which have rapidly grown in favour, namely, alfa, straw, wood, and jute.

Paper manufactured with alfa is supple, silky, tenacious, transparent, and very pure. It is, for the same weight, much thicker than any other kind. It acts very well for printing on, a quality much desired; it is also perfectly convenient for *editions de luxe* and for engravings.

Many of the best illustrated journals print on alfa paper, which is also used to make an excellent letter paper. An addition of alfa pulp greatly improves pure straw paper.

England consumes the largest part of the material furnished by the alfa countries, that is to say, Algeria, Spain, Tunis, Tripoli, and Morocco. Of the 225,000 tons of this product yielded in 1885, England took for her share nearly 200,000, and of this quantity of 225,000 tons exported from the alfa countries, the paper industry has taken 210,000, the other 15,000 have been used in the manufacture of cordage and basket-ware.

France uses very little alfa, because of the high cost of transport of chemical products and of coal.

In Algeria, the province of Oran has always preserved the alfa monopoly. At first, it was confined to the coast district, and the fields of alfa were at little distance from the sea; now the inland railways permit of an economic transport.

The value of the exportation of alfa from Algeria at present is estimated annually at 10 million francs. It is stated that on completion of all the ways of communication, Algeria will be able to produce annually 400,000 tons. Thus, in the department of Algeria, in the military territory, more than 6,000 hectares of alfa were wasted because of the difficulty of transport; this means a loss of 120,000 tons of the raw material.—*Board of Trade Journal*.

#### ASPHALT AND PETROLEUM IN MEXICO.

The proofs of the existence of petroleum in certain districts consist of two kinds, viz., large deposits of asphaltum (called here "chapopote") formed by the residue of oil, and flowing springs of the crude oil itself in a state of more or less density. The belt of country over which indications of oil extend is immense; in fact, the whole Atlantic coast of Mexico shows traces of it. But while these localities are distant from the coast and situated in a mountainous country in the southern part—for instance, in the State of Tabasco—in the northern portion of the Republic the deposits and springs are found on those extensive plains between the sea-coast and the foot of the mountains, very near to the sea and in most cases close to or on the banks of navigable rivers, such being the case in the district to which we refer, which must certainly be called the most important of all those around the ports of Tuxpam and Tampico. In these districts the deposits of asphaltum are of immense size and so favourably located that with a few miles of river navigation the open sea is reached. In some instances large vessels could go up almost to the spot; and in one case the deposits are in the immediate vicinity of the Tampico branch of the Mexico Central Railway. These deposits of asphaltum are of such pure composition that during the night they condense into a certain state of glossy hardness, whilst during the daytime the sun renders them so soft that the cattle passing over them sink down. The commercial value of this asphaltum has not been ascertained as yet, but it has been shipped with profit, in small lots, at various times, to the States and even to Europe, by the merchants of the coast. Its breaking or cutting on the spot amounts to next to nothing, and it can be thrown into the river and floated down to the sea-coast, where it may be collected again and loaded on the vessels. Some of the springs where crude petroleum runs out freely are situated on the very banks of rivers, the oil flowing into the same and covering the surface of the water for a great distance. A few samples of the different kinds of crude oil, some of which have been assayed in Pennsylvania, have turned out to be of a quality at least equal to the crude produced in that State. Some of these springs have a natural flow of a stream three inches in diameter.

Again, in the same districts, there exist in several places deposits or veins of a certain bituminous coal, which, upon careful examination by competent authorities, proved to be a very good class of "grahamite," which kind of coal has so far, if we are correctly informed, only been found in New Brunswick and somewhere in Virginia, which deposits are said to have given out. Its value is much greater than anthracite coal—perhaps three times as much—because of its superior qualities for the manufacture of gas. There is especially one deposit existing a few miles up the river from the city of Tampico, which, although not developed to any extent, has enough coal in sight to prove it to be an important deposit, worthy of careful investigation and further development.—*Ibid*.

#### REPORTS FROM BAKU.

Chem. Zeit. 14, 8.

According to the report of the Caucasian administration, the production of copper in 1888 amounted to 93,385 puds 17 lb.

On the 1st (13th) November there were in the peninsula Apochewn 432 productive naphtha borings; 231 in action,

110 at the time not in action, and in the case of 92 boring was going on. Four of the borings were in action as fountains. The maximum depth was 358½ metres, minimum depth 49 metres, average 192½ metres. The Government has offered to buy Nobel's naphtha-duct between Michailas and Kvirili.—N. H. J. M.

#### THE CONSUMPTION OF CUTCH.

The destruction of the cutch trees has been proceeding at such a rate during the last few years that the Government of British Burma has thought it necessary to adopt special measures for their protection.

During the last season cutch was also greatly mixed with a spurious article called "than," which deteriorated the quality considerably. The Government has, therefore, strictly prohibited the felling of "than" trees, and the market will not therefore be swamped this season by such inferior parcels as have accumulated in London and Liverpool, and now form a large portion of the stock there. The natives had also been cutting down the cutch trees indiscriminately, thus spoiling the forests. The Government, with a view to remedying this evil, have in some districts almost entirely withdrawn the licences from the native boilers, and only granted a very limited number in others.

These measures are reducing the output of cutch this season, and so far the shipments from Rangoon are less than one-third of those of 1889 and 1888.

The English stocks have yearly increased since 1887, owing to the vast amount of inferior cutch imported, which is unsuitable for most manufacturing purposes; but this nominally very large stock contains hardly 10 per cent. of really good consuming cutch.

The average consumption of cutch during the last four years is calculated to amount to 14,118 tons per annum.—*Ironmonger*.

#### THE OKRA PLANT AS A SUBSTITUTE FOR HENEQUEN.

Considerable attention is being directed to the okra plant, an annual of South American origin, which, heretofore, has been known chiefly, says the *South American Journal*, as furnishing an excellent vegetable for soups. It has recently been discovered, however, that this plant has an excellent fibre, and an American citizen asserts that he has invented a process for extracting okra fibre at a cost not exceeding 1 cent a pound. It is believed that okra fibre, especially if extracted at this price, will largely displace jute, and it is also likely to come into competition with henequen.—*Board of Trade Journal*.

#### PRODUCTION OF IRON IN INDIA.

See *Board of Trade Journal* for April, p. 465, quoting *Times of India* of February 21st, 1890.

#### SUGAR IN INDIA.

See *Journal of the Society of Arts*, April 4th, 1890, p. 495.

#### IMPORTANT PATENT DECISION.

The decision announced by the Supreme Court of the United States in the case of Pohl v. The Anchor Brewing Company is one of far-reaching consequences. The text of the decision is not yet printed, but the announcement is sufficiently full to show that the Supreme Court has held—overruling the Circuit Court of the Southern District of New York—that United States patents issued for inventions which have been previously patented abroad do not terminate when the foreign patents may happen to come to an end as a penalty for non-payment of taxes, importation in contravention to foreign laws, or other breaches of conditions subsequent on which those patents are issued.

The Westinghouse and Edison Companies have been in litigation for a long time on questions involving the one decided in this case, which is upon a patent for the washing of beer barrels. This case was availed of by the Edison and Westinghouse Companies, they having none of their own sufficiently forward to reach an early decision, and it was argued by their respective counsel. A judgment was rendered by Judge Wallace overruling his former decision

under the authority of *Bates v. Hammond*, which he interpreted as requiring him—apparently contrary to his convictions of what the decision ought to be—to declare the beer barrel patent expired here because of its forfeiture in Germany. The appeal from that decision was submitted out of its order under a rule of the court upon briefs signed by Mr. Grosvenor P. Lowrey, Mr. Benjamin F. Thurston, Mr. Clarence A. Seward, Mr. J. M. Denel, and Judge Davis on the one side, and by Mr. Wetmore, Witter and Kenyon, and Hess and Townsend upon the other. The fulness of the consideration which this question has now had seems to settle the law upon this point, and leave it certain that American patents can suffer no detriment by reason of those foreign patents, except to be limited to the term for which the foreign patent issues. Nothing done after that time by the foreign owner can prejudice the American interest.

It is believed that this decision is far-reaching to a degree that can scarcely be estimated. To the Edison Company alone the result is deemed of the greatest importance, since it is claimed by them that it rids them of the only serious difficulty in the way of establishing the principal Edison lamp patent; and doubtless other patents of a value nearly as great in various branches of industry which were compromised while this matter remained in doubt are now secured.—*Engineering and Mining Journal*.

#### THE ZINC WHITE INDUSTRY IN GERMANY.

The high prices of zinc have seriously restricted the trade in zinc white. The total production of the Silesian district last year amounted to only 715 tons, against 2,369 tons in 1888. Among the substitutes for zinc white, zinc dust, which is sold at three-fourths the price of the metal, is being more and more largely used. Another substitute, soapstone, used from time immemorial in China and Japan for painting metal-work, is also growing in favour in Germany.—*Industries*.

#### ANTIMONY ORES IN SPAIN.

The first lot of antimony ore, of great yield, from the Zalamea de Serena mines, in Estramadura, has been despatched to England. A large sample of this ore, sent to Germany, was analysed, and found to contain 15 grms. of gold per ton. As a rule, all the ores of that place, both antimony and silver lead, have shown more or less gold, but the company do not yet look upon their property as a gold mine.—*Ibid*.

#### THE NEW CALEDONIA MINES.

The New Caledonia mines, according to official reports, produced during the last fiscal year 8,423 tons of nickel ore, worth 125 frs. a ton; 3,020 of cobalt ore, worth 80 frs.; 236 of copper, at 300 frs.; 500 of lead, at 150 frs., and 2,475 tons of chrome ore, worth 40 frs. a ton.—*Chemist and Druggist*.

#### THE EXPORTS OF CHEMICALS.

The exports of chemicals from the Tyne for the first quarter of this year show a considerable increase in tonnage over the exports for the corresponding quarter of last year.

	1889.	1890.
	Tons.	Tons.
Alkali and soda ash .....	2,702	3,704
Bicarbonate of soda .....	26	24
Bleaching powder .....	3,911	6,424
Manure .....	1,963	2,955
Soda crystals .....	2,980	3,303
Sulphate of soda .....	187	1,107
Other chemicals .....	3,761	4,911
Total .....	15,539	22,428

Being a total increase of 44 per cent.

#### GLAZING A BLAST FURNACE LINING.

An experiment was tried at the Crown Point Iron Company's plant, Lake Champlain, N.Y., some time ago, on the occasion of their relining and starting in blast one of its large furnaces. After the fire-bricks were in place, a cheap article of graphite or plumbago, supplied by the Joseph Dixon Crucible Company, of Jersey City, N.J., was bought, reduced to a paste with water, and the interior of the furnace washed with the plumbago paste. It gave a slippery gloss to the fire-brick lining which refused to be coated with slag, and the charge passed down in less time and left the lining free and clear. The Crown Point managers claim quite a success for their scheme.—*Eng. and Min. Journal*, N.Y.

#### SALT SPRING IN THE MANCHESTER SHIP CANAL.

*Industries* states that a brine spring has been discovered in the cutting of the Manchester Ship Canal near Partington. The water from the spring is being tested in order to ascertain its strength and the probable richness of the assumed salt beds.

#### MINERALS IN SOUTH AFRICA.

The Transvaal appears to be very rich in minerals other than gold, and if we may place implicit reliance upon the statements recently made by Mr. W. H. Furlonge, of Johannesburg, it possesses most of the elements of success for the making of iron and steel. Mr. Furlonge remarks the almost entire absence of lime throughout the country, which would be very prejudicial to blast-furnace work, but silica is most abundant, and oxides of iron are to be found everywhere amongst the rocks. Many of the "bars" of oxides, containing 30 to 40 per cent. of iron, are alongside deposits of auriferous quartz, and the ironstone itself carries gold, so that it is one of the possibilities of the future Transvaal iron trade that gold may be raised with iron instead of being made out of it! In addition to these "bars" of ironstone, there are amongst the schists and shales of the De Kaap district of the Transvaal enormous deposits of iron ore, some of the stratified beds being hundreds of feet thick, and of almost pure hematite, with some magnetite. Mr. Furlonge says that some, at least, of these are Bessemer ores, and he predicts that the Transvaal will never be at a loss for iron ores. There is coal in inexhaustible quantities in the High Veldt, within about seventy miles of the iron-ore deposits, consequently it seems to be only a question of time for the two to be used in conjunction for the production of iron, or even of steel, by the pneumatic or open-hearth process. Of other minerals—lead, mercury (cinnabar), nickel, cobalt, copper, and antimony—the Transvaal has plenty, and Mr. Furlonge, who is a practical geologist, hints at the growth of a large silver-mining industry, seeing that some of the galena on the High Veldt contains silver up to as high as 600 oz. to the ton. The great want of this rich mineral country is railways, and as soon as they are made on a proper scale we may anticipate considerable developments on all sides.—*Ironmonger*.

#### EXTRACTS FROM GEIHE AND CO.'S REPORT.

##### Acid (Carbolic).

In Germany the use of carbolic acid has grown very considerably in the last few years, since this acid has been used more frequently than formerly in the preparation of stores for war. The home production has not been at all equal to fill the increased demands, but the assistance of foreign makers had to be invoked, with the result that the imports advanced from 698,200 kilos. in 1887 to 1,191,800 kilos. in 1888 and 2,432,100 kilos. last year. Of the 1889 imports, 2,267,800 kilos. came from England. The interest in synthetically-made carbolic acid has perceptibly fallen off since it became clear that the new article shared with the old one the fatal defect of reddening. It is true that the synthetic acid possesses some few advantages over the coal-tar product, but not sufficient to compensate for the important difference in price, particularly as the Imperial Department of Health has ascertained that the disinfecting properties of both acids are equal.

*Ambergris.*

It is but natural that the excessive prices demanded for this article should have had the effect of diminishing the demand, but however dear it may be there are always perfumers who will not do without this favourite article. If we consider, however, that by a suitable treatment of the combinations belonging to the aromatic acid series it has been possible to obtain a substitute for musk, it does not seem beyond the reach of possibility to manufacture synthetic ambergris also, the natural product consisting principally of a peculiar non-saponifiable fat. Such a discovery would have the result of putting an effectual limit to such exorbitant quotations as are now made, while the discoverer would be sure to reap a material reward from the constant demand of this article, which does not depend upon fashion.

*Borax.*

The present year has not brought any alterations in the price of borax, and so long as the union of the manufacturers continues to exist the market will retain its stability. Whether this combination can be maintained in future is questionable, because the German production grows every year at the expense of the British output. The German Imperial statistics show an increase in the exports of borax and boracic acid from 800,900 kilos. in 1887, to 1,172,500 kilos. in 1888, and 1,664,200 kilos. in 1889.

*Camphor.*

The large Hamburg refineries are now sold out, and it is difficult to form an opinion of the future of the article, as the principal consuming time is now approaching. It is also impossible to indicate the true causes of the advance. It is a fact that the consumption of camphor has enormously increased in consequence of its use in industrial purposes, both in blocks and in powder, while the imports remained small, and there is no means of judging whether and when it will again increase. The annual consumption of raw camphor in the United States is said to have averaged 2,100,000 lb. during the last four years, while the importation last year decreased by 1,200,000 lb. This deficiency has to be provided for from elsewhere, and this conclusion agrees with the reports spread from Hamburg that one large firm in the States will not only require for this year a surplus of 600 kegs of refined camphor over its usual consumption, but has not even covered as yet the principal part of its usual requirements of 800 kegs. As regards the question whether the supplies of raw camphor are kept back artificially in Japan, or whether the production has really diminished in the same measure as the supply, has hitherto been considered as an unsolved question; but the alleged diminution of the production is a favourite explanation of the smallness of the quantity offered. According to reports from an official source in Japan, it is quite possible that there may have been some limitation of the production, but the reduction in the quantity offered is entirely the result of the manoeuvres of native speculators in the primary markets. But already, last year, it was said that the advance in the price of raw camphor was caused by the wholesale destruction of trees by the natives. As regards the speculative rushing up of prices since the middle of February, that movement is said to have been caused by the fact that certain Japanese firms had requested their buyers in Europe to cancel existing contracts against payment of heavy damages, their requests being partly successful. The consequence of these cancellings was, of course, that the buyers had to cover their own contract sales of refined camphor, producing thereby a considerable excitement in the market. In view of the present elevated prices of camphor, it would not be surprising if experiments were to be made to find a substitute for it in the manufacture of smokeless gunpowder. To that purpose, about 8 per cent. of camphor was required, in addition to about 72 per cent. of nitro-glycerin and 20 per cent. of pyroxylin. The idea may be brouched to manufacture on a cheap scale, and for experimental purpose hydrochloric acid camphor, which in former years had a short run as artificial camphor. Perhaps the strong evolution of gas from this compound might render it specially suitable (?) for this purpose.

*Phosphorus.*

The dissolution of the union for the fixing of the phosphorus prices between the English and the French manufacturers has brought about a struggle of the respective works for the possession of the German and Austrian markets, which has resulted in a reduction in the quotations. The German Imperial statistics show that in 1889 the English makers succeeded in maintaining the field against their French competitors; but, on the other hand, the competition of the Russian works is becoming somewhat more perceptible. The imports of white and red phosphorus in 1889 were 266,800 kilos., against 136,300 kilos. in 1888. Of the former quantity, 212,500 kilos. came from England, 38,300 kilos. from Russia, and 2,100 kilos. from France.—*Chemist and Druggist.*

## EXPORTS OF DRUGS AND CHEMICALS FOR MONTH ENDED 31ST MARCH.

Articles.	Quantities.		Values.	
	1889.	1890.	1889.	1890.
			£	£
Alkali..... Cwt.	528,296	417,209	131,292	128,492
Bleaching materials ..	113,494	109,129	43,370	29,417
Chemical manures. Tons	26,598	28,211	191,812	189,807
Medicines..... Value £	..	..	92,250	92,459
Other articles ... ..	..	..	228,744	270,986
Total value .....	..	..	680,477	741,152

## EXPORTS OF MISCELLANEOUS ARTICLES FOR MONTH ENDED 31ST MARCH.

Articles.	Quantities.		Values.	
	1889.	1890.	1889.	1890.
			£	£
Gunpowder..... Lb.	756,260	948,600	17,905	23,435
Military stores.. Value £	..	..	86,989	106,505
Candles..... Lb.	833,400	1,256,800	16,418	23,016
Caoutchouc .... Value £	..	..	98,392	94,297
Cement..... Tons	66,026	57,655	127,423	117,603
Products of coal Value £	..	..	96,750	133,351
Earthenware ... ..	..	..	194,828	139,641
Stoneware ..... ..	..	..	18,128	17,699
Glass:—				
Plate..... Sq. Ft.	378,568	256,550	22,700	12,642
Flint..... Cwt.	11,912	12,337	26,765	23,423
Bottles..... ..	82,033	75,276	38,696	35,011
Other kinds.... ..	17,995	13,674	14,336	11,963
Leather:—				
Unwrought .... ..	13,458	12,734	123,130	115,482
Wrought ..... Value £	..	..	37,180	29,307
Seed oil..... Tons	6,446	5,673	133,273	129,985
Floor cloth ..... Sq. Yds.	1,549,800	1,608,900	72,859	70,081
Painters' materials..... Value £	..	..	140,272	132,839
Paper ..... Cwt.	90,489	83,313	159,955	147,389
Rags..... Tons	4,920	3,427	41,812	26,470
Soap..... Cwt.	35,577	40,186	40,798	45,792
Total value .....	..	..	2,940,056	2,800,032

## TRADE BETWEEN SPAIN AND THE UNITED KINGDOM.

## IMPORTS INTO THE UNITED KINGDOM FROM SPAIN FOR THE THREE MONTHS ENDED 31ST MARCH.

Principal Articles.	Quantities.		Values.	
	1889.	1890.	1889.	1890.
			£	£
Chem. products unenumerated Value £	..	..	12,469	8,471
Copper ore and regulus ..... Tons	25,229	15,829	399,853	271,731
Iron ore ..... ..	990,734	1,138,142	703,911	907,027
Lead ore..... ..	170	320	1,260	2,870
Lead, pig and sheet ..... ..	18,913	19,174	242,233	251,201
Manganese ore.. ..	1,430	2,350	2,860	5,250
Olive Oil..... Tons	1,082	484	36,592	18,287
Pyrites of iron and copper ... Tons	201,643	156,487	493,593	305,730
Quicksilver ..... Lb.	1,389,555	1,534,914	151,403	209,010
Rags, esparto ... Tons	21,704	20,687	133,196	118,102
Zinc ore ..... ..	4	577	25	1,841
Total value .....	..	..	3,079,821	3,162,431

## EXPORTS OF HOME PRODUCE FROM THE UNITED KINGDOM TO SPAIN FOR THE THREE MONTHS ENDED 31ST MARCH.

Principal Articles.	Quantities.		Values.	
	1889.	1890.	1889.	1890.
			£	£
Alkali..... Cwt.	76,216	64,686	22,679	22,519
Caoutchouc manufactures .... Value £	..	..	4,123	3,233
Cement..... Tons	1,350	1,483	2,180	2,893
Chemicals (including dye-stuffs) ..... Value £	..	..	20,691	49,034
Products of coal .. ..	..	..	13,256	17,942
Glass manufactures ..... ..	..	..	1,667	1,629
Manure..... ..	..	..	60,294	52,456
Oil, seed ..... Tons	131	135	2,640	3,067
„ other sorts.. Value £	..	..	2,843	9,235
Painters' colours &c. .... ..	..	..	7,657	7,688
Paper of all sorts Cwt.	1,388	1,183	3,799	2,951
Sap..... ..	201	437	249	547
Oil and floor cloth ..... Sq. yds.	89,109	88,609	3,791	3,761
Total value .....	..	..	1,080,138	1,270,562

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### APPLICATIONS.

4225. J. von Langer and L. Cooper. Improvements in or connected with valves for hot gases. March 18.

4309. J. Foster. Improvements in and relating to evaporating and distilling apparatus. March 19.

4354. A. Eickhorn and R. Jaspar. Improvements in hydrometers. Complete Specification. March 20.

4532. E. G. Lawrence.—From S. Pick, Galicia. See Class VII.

4562. J. Coppard. Improvements in the construction of appliances for extracting the juices from fruits and other substances. March 24.

4594. E. Jones. Improved apparatus for separating liquids or solids from vapours or gases in which they are suspended. March 24.

4802. G. C. Topp. Improvements in hydrometers, saccharometers, and lactometers. March 27.

4822. H. A. A. Dombrain. See Class XX.

5038. H. Trott. Improvements in apparatus for operating valves for controlling the passage of fluids. April 1.

5142. E. Theissen. Improvements in apparatus for condensing steam and other condensable vapours or gases. April 2.

5267. A. Chapman. Improvements in the construction and working of double, triple, and multiple effect evaporating apparatus. Complete Specification. April 5.

5419. J. Guillaume. Improvements in the treatment of organic matters. Complete Specification. April 9.

5598. H. A. Fleuss. Improvements in freezing or refrigerating apparatus. April 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1889.

5592. W. L. Wise.—From Escher Wyss and Co. Manufacture of clear ice, and apparatus therefor. April 2.

6391. W. Hucks. Method and means for separating solids from liquids. April 15.

8184. J. J. Hicks. Improvements in brewers' and other thermometers. March 26.

8687. E. F. Varaldi. Vacuum pumps. March 26.

8882. W. P. Branson and H. W. Neild. See Class VIII.—A. April 9.

9354. F. J. Brough. — From S. Jonsson. Centrifugal separating machines. April 9.

9375. G. King. Fastenings for retort lids. April 2.

1890.

1910. J. F. H. Gronwald. Sterilising apparatus. April 2.

### II.—FUEL, GAS, AND LIGHT.

#### APPLICATIONS.

4197. H. L. Müller and W. Adkins. Improvements in apparatus for the production of lighting gas. March 18.

4217. L. van Vestrout. Improvements in apparatus for charging inclined gas retorts. March 18.

4223. J. von Langer and L. Cooper. Improvements relating to the production of water-gas and generator-gas, and to apparatus connected therewith. March 18.

4224. J. von Langer and L. Cooper. Improvements in apparatus for the generation and enrichment of water-gas and producer-gas. March 18.

4236. W. E. Smith.—From S. T. J. Bray, Russia. Improvements in apparatus for burning liquid fuel. March 18.

4324. J. A. Kehuan. Improvements in apparatus connected with the manufacture of gas. March 19.

4326. C. A. Sahlström and A. F. Hill. An improved burner for liquid fuel. March 19.

4355. D. Hancock and J. B. Craig. Improvements in carburated air-gas produced from mineral oils or spirits. March 20.

4374. F. R. Engledow and The Engineering Joint Stock Company. Improvements in heating and heating apparatus. March 20.

4457. E. Edwards.—From F. Strohmer, Germany. Improvements in coke ovens and in the method of using the same. March 21.

4542. T. C. Fawcett and J. B. Swallow. A new manufacture of briquette or block fuel. March 24.

4598. W. Gray. Improvements in the manufacture of gas. March 24.

4708. R. M. Whitaker. Improvements in apparatus for utilising the waste heat from steam-boiler and other furnaces, and applying it to the heating of air to support combustion and consume smoke in those furnaces. March 26.

4928. The Manchester Oxygen Company, Lim., and W. M. Jackson. Improvements in the mode of using compressed gases for illuminating purposes. March 29.

4936. S. Girding. Improvement in a mantle or filament holder and burner for incandescent gas lamps. March 29.

5078. C. Hunt. Improvements in inclined gas retorts and in apparatus for charging the same. April 1.

5163. S. J. Woodhouse. Improvements in the mode and means employed for charging and discharging retorts used in the manufacture of gas. April 3.

5194. G. Waller. Improvements in apparatus for cooling and conveying coke discharged from gas retorts into suitable receptacles or places. April 3.

5239. J. Blum. The instantaneous production of water-gas. April 5.

5243. H. Fourness. Improvements in apparatus for carburetting water-gas. April 5.

5434. H. Williams. Improvements connected with the manufacture of water-gas and other gases for lighting and manufacturing purposes. April 10.

5453. W. Ackroyd, T. H. Ackroyd, and J. Willoughby. Improvements in the method of and apparatus for effecting or increasing the combustion of smoke in steam-boiler and other furnaces, and in the utilisation and transmission of heat produced therein, and for economising fuel and improving the draught. April 10.

5461. J. G. Hawkins and J. Barton. Improvements in vertical gas retorts, together with their lids, doors, and other attachments. Complete Specification. April 10.

5485. J. Westray. Improvements in apparatus for the better combustion of fuel, and supplying hot air to steam-boiler or other furnaces. April 11.

5543. E. Manbre. Improvements in the burning of liquid fuel, and in apparatus or furnaces therefor or appertaining thereto. April 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

9279. B. Loomis. Process and apparatus for manufacturing heating and illuminating gas. April 9.

9327. S. Fox and E. Blass. Manufacture of water-gas and apparatus therefor. April 9.

9454. G. Love. Apparatus for generating and consuming combustible gas. April 16.

11,456. N. Meiklejohn. Anti-dips for hydraulic mains employed in the manufacture of gas. April 9.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

## APPLICATION.

4120. J. Laing. Improvements in the apparatus for destructive distillation of mineral oils at atmospheric pressure. March 17.

### IV.—COLOURING MATTERS AND DYES.

## APPLICATIONS.

4382. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture of new derivatives of phenyl-amido-acetic acid. March 20.

4577. O. Inray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Improvements in the production of grey colouring matters. March 24.

4596. S. Pitt.—From L. Cassella and Co., Germany. The manufacture of sulphonated thionines. March 24.

4901. S. Pitt.—From L. Cassella and Co., Frankfurt-on-Maine. Improvements in the manufacture of dyestuffs. March 28.

4930. W. Hay, W. M. Alexander, and E. Bentz. Improvements in the preparation or admixture of indigo with certain substances for commercial and industrial purposes. March 29.

4946. O. Inray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Production of ethylether of cinnamic acid. March 29.

5155. The Clayton Aniline Company, Lim., and J. Hall. Improvements in the manufacture of colouring matters. April 2.

5455. J. Mills. A new or improved application of ceramic colouring matters, or colouring matters obtained from metallic oxides to india-rubber, gutta-percha, vulcanite, or other like substances or materials. April 10.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

7802. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture of azo-dyes and materials therefor. April 16.

7857. O. Inray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of a new colouring matter of the induline series. April 16.

7977. S. Pitt.—From L. Cassella and Co. Production of bluish black colouring matters. March 26.

8373. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. Preparing colouring matters of the oxyketone group for dyeing and printing. March 26.

9428. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. Preparing colouring matters of the oxyketone group for dyeing and printing. March 26.

9429. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. Production of coloured compounds of galactophenone within or upon animal and vegetable fibres. March 26.

9612. J. Y. Johnson.—From F. von Heyden. Manufacture of beta-naphthol carbo acid. April 16.

9642. O. Inray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Production of oxysulphonic acids and naphthalin. April 16.

9643. O. Inray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Production of colouring matters from oxysulphonates of naphthalin.—April 16.

11,000. H. H. Lake.—From W. Oehler. Production of colouring matters. April 9.

12,549. T. R. Shillito.—From A. Feer. Manufacture of yellow to orange colouring matters.—April 2.

### V.—TEXTILES, COTTON, WOOL, SILK, Etc.

## APPLICATIONS.

4231. H. Smith, E. D. Smith, and H. D. Smith. Improvements in the method of and apparatus for washing wool and other fibres. March 19.

4452. H. A. Lowe. Improvements in the treatment of or finishing of manufactured or partially manufactured materials from cotton or other cellulosic fibres. March 21.

4958. T. Burrows. Means and machinery for removing the fibrous filaments from fibre-bearing leaves and stems of plants. March 29.

5271. J. Saleha. A new or improved process for cleaning and separating cotton from the cotton seeds. April 5.

5413. W. P. Thompson.—From H. Orval, France. Improvements in and apparatus for drying, cleaning, or otherwise treating wool. April 9.

5482. G. W. Arnott, P. A. Olivier, and G. Sengrave. An improved process for washing and scouring wool and fibrous materials containing grease. April 10.

5532. C. L. Field. A process for decorticating ramie and other fibrous stems. April 11.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

7058. B. W. Weatherdon.—From T. A. Compere. See Class IX.

7090. C. Dreyfus and J. Robinson. Manufacture of india-rubber or waterproof textile fibres and fabrics. April 9.

8106. V. Schevelin and P. Mindovsky. Treating vegetable fibres by acid, neutral, and alkaline residues of naphtha manufacture or specially prepared substances analogous to such residues. April 2.

### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

## APPLICATIONS.

4409. J. O. Muller and C. O. Weber. Improvements in dyeing vegetable and certain animal fibres a fast aniline black, said fibres being either in the loose or manufactured state. March 21.

4450. W. Turnbull, W. Stockdale, and G. Duerr. Improvements in the process of mordanting cotton or other vegetable fibrous materials. March 21.

4610. G. Newsum. Improvements in apparatus for applying bronze and other powders to the surface of paper and the like. March 25.

4683. A. J. Boulton.—From A. Koblenzer and M. Koblenzer, Germany. Improvements in or relating to the dyeing of yarns. Complete Specification. March 25.

4854. W. E. Heys.—From E. Châtel, France. Improvements in machines for dyeing, bleaching, and similarly treating yarn and threads in cops and bobbins. March 28.

5054. C. Kellner. *See* Class XI.

5285. C. Kellner. Improvements in the process of and apparatus for bleaching vegetable fibres. April 5.

5385. W. E. Heys.—From E. Châtel, France. Improvements in apparatus for steeping, dyeing, and otherwise treating yarn and similar textile materials in cops and bobbins. April 9.

5547. B. Haigh. Improvements in dyeing and apparatus therefor. April 12.

#### COMPLETE SPECIFICATION ACCEPTED.

1889.

9149. S. Mason, jun. Apparatus for dyeing and otherwise treating wool. April 16.

### VII.—ACIDS, ALKALIS, AND SALTS.

#### APPLICATIONS.

4171. C. S. Negrier. Improved method and apparatus for concentrating sulphuric acid. March 17.

4394. F. Ricard. Improvements in the manufacture of soda by the ammonia process. March 20.

4434. J. J. Meldrum and T. F. Meldrum. Improvements in or connected with apparatus used in the distillation of ammonia. March 21.

4435. J. J. Meldrum and T. F. Meldrum. Improvements in or connected with apparatus used in the distillation of ammonia. March 21.

4473. H. H. Lake.—From La Société Anon. Jay et Jellathier, France. Improvements in apparatus for producing carbonic acid and similar gas. March 21.

4519. H. Precht. An improved process for the production of potash from potassium and magnesium carbonate. March 22.

4532. E. G. Lawrence.—From S. Pick, Galicia. Improvements in apparatus for evaporating liquors containing salts, and for separating such salts, when rendered insoluble by evaporation of the liquors. March 22.

4588. H. Precht. Improvements in the process or apparatus for the production of carbonate of magnesium and double carbonate of magnesium and potassium. March 24.

4652. J. C. Mewburn.—From C. C. Peck, United States. Improvements in purifying brine. Complete Specification. March 25.

4694. E. G. Lawrence.—From S. Pick, Galicia. Improvements in the manufacture or production of salts from brine. March 25.

4695. E. G. Lawrence.—From S. Pick, Galicia. Improvements in apparatus for drying salt. March 25.

4751. E. A. Cowper. Apparatus for producing fine salt from brine. March 26.

4759. H. Precht. An improved process for the production of hydrate of magnesia. March 26.

4780. B. H. Thwaite. The treatment of salt preparatory to its dechlorination by sulphurous acid. March 27.

4950. A. W. Ellis. Improvements in the distillation of ammoniacal liquors, and in the apparatus to be employed therein. March 29.

5058. E. Delplace and J. Delplace. Improvements in or connected with apparatus for the manufacture of sulphuric acid. April 1.

5072. L. Mond. Improvements in treating phosphatic minerals. April 1.

5205. T. Wilton. Improvements in saturators used in the manufacture of sulphate of ammonia. April 3.

5287. L. J. de Graef. Improvements relating to the manufacture of phosphates and to apparatus therefor. April 5.

5442. C. A. Burghardt. Improvements in the manufacture of nitrate of ammonium and of resulting by-products. April 10.

5469. R. H. Wilson. Improvements in the manufacture of sulphuric acid, and in apparatus therefor. April 10.

5488. W. Donald. Improvements in obtaining chlorine. April 11.

5571. A. Campbell and W. Boyd. Improvements in obtaining chlorine and in utilising calcium chloride or other by-products. April 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

6172. F. M. Lyte. Production of magnesia chloride and magnesia oxychlorides. April 9.

6433. W. Schlenking. *See* Class IX.

6968. J. Hargreaves, T. Robinson, and T. Hargreaves. Obtainment of sulphuretted hydrogen, sulphur and cement from black ash and alkali waste, and apparatus therefor. March 26.

7733. The Alkaline Reduction, Lim., and A. B. Cunningham. Recovery of soda from slags containing same. April 2.

8841. C. A. Burghardt. Manufacture of nitrate of ammonium and resulting by-product. April 16.

19,225. T. Wilton and G. Wilton. Manufacture of sulphate of ammonia and apparatus therefor. April 9.

1890.

1653. G. Kennedy. Saturators for sulphate of ammonia plant. March 26.

### VIII.—GLASS, POTTERY, AND EARTHENWARE.

#### APPLICATIONS.

4356. A. J. Wilkinson. Improvements in ovens for firing pottery. March 20.

4504. E. P. Lee. Improvements in kilns for burning bricks, tiles, and other clay goods. March 22.

4509. D. Rylands and B. S. Shepeote. Improvements in or applicable to machinery for the manufacture of glass bottles or other hollow glass ware. March 22.

4592. H. T. Parfitt. Improvements in kilns or ovens for firing glass, enamel ware, and for other purposes. March 24.

4792. D. Rylands and A. Hisselbee. Improvements in the manufacture of glass-lined fittings for glass-lined piping. March 27.

4800. C. Cockburn. Enamelling, rendering opaque or discernible, raised or indented designs on glass utensils, &c. March 27.

5079. S. Washington. Improvements connected with the manufacture of glass bottles and other hollow glass ware. April 1.

#### COMPLETE SPECIFICATION ACCEPTED.

1889.

8511. E. Bussy. Compounds for manufacture of pottery goods in general, and combination of ingredients for manufacture of white enamel or opaque colours as a surface or glaze for said bodies. April 2.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

## APPLICATIONS.

4741. W. A. Gibbs. Improvements in kilns for cement and the like. Complete Specification. March 26.

4995. G. A. Mansfield. Road paving by composite block process. Complete Specification. March 31.

5206. J. Chambers. A new or improved material for light roofing and such like purposes. April 3.

5349. C. O. Weber and G. F. Freeman. Improvements in the manufacture of artificial stones, slabs, or compositions for building and other purposes. April 8.

5515. P. M. Justice.—From S. W. Parker and A. Gates, New York. An improved material for building purposes. April 11.

5533. A. McLean. Improvements in asphalt paving. April 11.

5581. G. H. Skelsey. Improvements in kilns, more especially applicable to cement kilns. April 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

6433. W. Schlenning. Application of the residues of soda manufacture for building purposes. April 16.

7058. B. W. Weatherdon. — From T. A. Compere. Combining and treating hemp, flax, jute, &c., and employing same for roofing and building purposes. April 2.

8145. G. P. Gildea. Making cement from chalk, marls, and argillaceous limestones, and utilising poor clays for making cement, and apparatus therefor. March 26.

10,824. J. Brunton and L. Griffiths. Apparatus for mixing the materials used in manufacture of artificial stone, concrete, &c. April 16.

## X.—METALLURGY, MINING, Etc.

## APPLICATIONS.

4201. T. Teague. Improvements in smelting furnaces for treating tin ores, slags, or debris, or other metallic matters. March 18.

4386. J. von Ehrenwerth. Method for producing iron from ores. Complete Specification. March 20.

4420. J. T. Beilly and G. G. Henderson. The extraction of metals from their ores and apparatus therefor. March 21.

4560. T. Teague. Improvements in processes for refining raw tin and extracting and utilising the combined metals. March 24.

4631. R. H. Radford. Improvements in casting compound or composite metallic ingots and other metallic castings, and in machinery and appliances connected therewith. March 25.

4675. R. T. Tiefert. Improvements in the welding of metals. Complete Specification. March 25.

4690. H. J. Haddan.—From G. Conkling, United States. A process for concentrating magnetic iron ore. Complete Specification. March 25.

4752. D. Cameron.—From R. Pearce, United States. Improved process of extracting silver from copper ores, mattes, and other copper products. March 26.

4832. R. N. Oakman, jun. Improvements in furnaces for melting, heating, and welding metals. March 27.

5003. A. K. Eaton and K. A. Vanderbilt. Improvements in processes for obtaining chromium and chromium-alloys. Complete Specification. March 31.

5140. W. A. Thoms. Improvements in coating metallic and other surfaces with metals and alloys. April 2.

5199. The Electric Construction Corporation, Lim., T. Parker, and A. E. Robinson. Improvements in the treatment of copper nickel matte and the obtainment of products therefrom. April 3.

5306. W. E. Langdon. The detection of flaws or impurities in steel and iron. April 8.

5319. J. Lewthwaite. Improved method of operating upon and improving the quality of iron in the process of converting it into steel. April 8.

5407. O. Lumaghi. Improvements in apparatus for the reduction of argentiferous or other zinc ores. April 9.

5545. A. Turner, A. Baird, and M. B. Baird. Improvements in the manufacture of iron and steel. April 12.

5546. B. Mountain. Improvements in the manufacture of wire from copper, zinc, lead, brass, or other ductile metals or alloys. April 12.

5569. A. C. Kirk. Improvements in the manufacture of armour plates. April 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

5578. J. H. Pollok. Improvements in wet method of extracting gold. April 2.

7443. J. McCann. Blast furnace blocks and tuyères. April 16.

7666. G. Bamberg. Reducing aluminium by the action of molten metals, particularly iron, zinc, copper, and lead, on chloride of aluminium, or double chloride of aluminium and sodium. April 16.

7667. G. Bamberg. Reducing aluminium by the action of zinc vapour on chloride of aluminium or double chloride of aluminium and sodium. April 9.

8297. F. Bachschmid. Inlaying metals. March 26.

8492. J. Riley. Manufacture of steel or steel-like compounds. March 26.

8543. T. Twynam. Carburisation of steel or ingot iron. March 26.

8608. R. L. Consins. Process and apparatus for extracting precious metals from ores or quartz. March 26.

8822. E. Matheson. Manufacturing pots or crucibles of wrought iron or other malleable metals. April 2.

9358. R. E. Green. Production of alloys of aluminium. April 9.

9592. S. Alley. Apparatus for treating metallic ores or compounds with chemicals. April 9.

9632. T. Parker. Pickling and preparing iron for galvanising. April 16.

9784. W. White. Distillation of sodium and potassium, and their alloy. April 16.

11,788. D. Dennes.—Partly from T. K. R. Denver. Obtaining precious metals from their ores, and apparatus therefor. April 2.

19,334. W. L. Wise.—From B. Natuseh. Production of solutions of the chlorides of nickel and cobalt and other metals from ores or products containing them. April 9.

1890.

3782. L. Pszczolka. Obtaining uniform products from the Thomas converter, Siemens open hearth, and other basic furnaces. April 16.

## XL.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### APPLICATIONS.

4191. T. D. Farrall. Improvements in method and mechanism for generating heat, steam, and light by electricity. Complete Specification. March 18.

4246. Sir C. S. Forbes, Bart. Improvements in primary batteries, and in apparatus connected therewith. March 18.

4383. J. Pitkin and H. C. L. Holden. Improvements in the preparation of active or storage material for use in secondary batteries or accumulators. March 20.

4384. J. Pitkin and H. C. L. Holden. Improvements in plates for secondary batteries or accumulators. March 20.

4648. P. F. Degn. Improvements in the construction of dynamo-electric machines. March 25.

4657. H. H. Lake.—From E. Thomson, United States. Improvements relating to the soldering or uniting of metals by electricity and to apparatus therefor. Complete Specification. March 25.

4943. W. Balch and S. S. Bromhead. Improvements in batteries for electrical purposes. March 29.

4949. L. Weigert. An improved electrolytic solution for galvanic batteries. Complete Specification. March 29.

5049. A. de Méritens. Means for effecting the sterilising of liquids by electricity. April 1.

5054. C. Kellner. Improvements in the process of bleaching fibrous material by aid of electricity. April 1.

5228. W. P. Thompson.—From L. Hoppe and G. Hoppe, Germany. Improvements in galvanic elements. April 3.

5400. R. Schorch. Improvements in dynamo-electric machines. April 9.

5420. C. Kellner. Improvements in the process of, and means for, the manufacture of cellulose with the aid of the electric current. April 9.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

13,818. V. H. Ernst. Secondary batteries. April 2.

1890.

1281. V. H. Ernst. Secondary batteries. April 2.

1878. J. B. Williams. Electric insulating compounds. April 9.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

### APPLICATIONS.

4607. W. E. Crane. An improved process of filtering oil. March 25.

4809. J. Y. Johnson.—From M. Duclou, France. Improvements in the manufacture of soap. Complete Specification. March 27.

5226. W. P. Thompson.—From R. Krause, Prussia. A new or improved lanolin compound, and process for preparing and utilising the same, specially applicable to the preparation of lubricants. Complete Specification. April 3.

5375. E. Noppel, B. Grosche, and J. Bigler. Improvements in apparatus for purifying and refining oil. Complete Specification. April 8.

### COMPLETE SPECIFICATION ACCEPTED.

1890.

540. J. L. Wade. Improved non-freezing and lubricating oil. April 2.

## XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

### APPLICATIONS.

5342. E. Bruce. A varnish or enamel for leather. April 8.

5380. A. F. St. George. An improved method of and apparatus for preparing copal and other gum-resins and resins, and manufacturing varnish. April 9.

5387. D. Fulton.—From D. F. Schmid, United States. An improved manufacture of anti-corrosive compound. Complete Specification. April 9.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

### APPLICATION.

5004. A. Foelsing. Process for clarifying and bleaching tannin extracts or tannin liquors. March 31.

### COMPLETE SPECIFICATION ACCEPTED.

1889.

8191. J. Kristen. Process and means for dyeing hides. March 26.

## XV.—AGRICULTURE AND MANURES.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

8782. A. Booty. Manurial composition or stimulant for vegetable produce. April 2.

19,225. T. Wilton and G. Wilton. See Class VII.

1890.

2238. C. W. Doughty. Means and proportions of materials used for the deodorisation, evaporation and decomposition of human excrement, and its transformation into a nearly inodorous fertiliser. March 26.

2450. F. Dorr. Treating cereals. April 9.

## XVI.—SUGARS, STARCHES, GUMS, Etc.

### APPLICATIONS.

4181. S. Spitzer. Improvements in the method of and apparatus for the manufacture of starch and other products. March 17.

4513. J. Duncan. Improvements in the treatment of molasses or syrup obtained from beetroot. March 22.

4754. A. J. Boulton.—From L. Bon, Cuba. Improvements in or relating to apparatus for drying sugar-cane trash. Complete Specification. March 26.

5282. G. F. Redfern.—From M. Wienrich. Improvements in washing and cleaning raw sugar. April 5.

5283. G. F. Redfern.—From M. Wienrich, United States. Improvements in the manufacture of sugar. April 5.

## XVII.—BREWING, WINES, SPIRITS, Etc.

## APPLICATIONS.

4108. J. McKinless. Improvements in maturing spirits and other liquors and apparatus connected therewith. March 17.

4550. E. Rudgard. A new or improved nourishing stout or beverage. March 24.

4746. S. Joseph and H. Citron. Fermenting process in rarefied air-space. March 26.

4876. W. E. Gedge.—From E. J. Fraser, United States. New apparatus for improving wine and other alcoholic liquors. March 28.

4982. M. Hanford. An apparatus for cooling and aerating the hot worts for the production of malt liquors. March 31.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

221. A. Perry. Preparation of rice and other grain or cereals for brewing, &c., and apparatus therefor. April 16.

9181. E. Luck. Purification of alcohol and alcoholic liquors, and apparatus therefor. April 2.

9280. S. Herschler. Apparatus for agitating and turning over malt, &c. March 26.

10,762. T. Vogel. Apparatus for treating yeast. March 26.

15,772. J. Bruce. Manufacture of yeast. April 2.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

## APPLICATIONS.

*A.—Chemistry of Foods.*

4266. P. Jacoby. Automatic apparatus of domestical and industrial use for to sterilise milk. Complete Specification. Filed 18th March. Date applied for, 16th August 1889, being date of application in France.

4554. J. Shoveller. An improved cooked food for horses, cattle, and other animals. March 24.

4701. E. Sonstadt. Improvements in stoppering or closing vessels containing solid or liquid articles of food or other organic matters in order to exclude micro-organisms, and in sterilising such matters conjointly with the stoppering. March 25.

4979. G. W. Thomas. Improvements in the preservation of eggs. March 31.

*B.—Sanitary Chemistry.*

4151. F. P. Candy. Improvements in the manufacture of materials for use in the purification and clarification, and decolouration of water and sewage and other liquids, and for other uses. March 17.

4500. R. S. Brownlow. Improvements in the construction of apparatus for removing the solid and flocculent matters from impure water. March 22.

4732. W. Birch. Improved apparatus for filtering sewage and other liquids. March 26.

4836. J. Preece. Improvements in the treatment of sewage. March 27.

5113. J. Stilling. Improvements relating to a method of destroying microscopie organisms for disinfecting and other purposes, and to substances used therefor. April 2.

*C.—Disinfectants.*

4151. F. P. Candy. See Class XVII.—B.

5438. J. Wheeler. An improved antiseptic deodorant and germicide, also particularly for preventing the ravages of moths, book worms, and other insect pests. April 10.

## COMPLETE SPECIFICATIONS ACCEPTED.

*A.—Chemistry of Foods.*

1889.

5356. H. W. Harr. Manufacturing food in a concentrated cooked form. March 26.

6280. J. F. H. Gronwald and E. H. C. Oehlmann. Method and apparatus for preparing milk so as to enable it to be preserved indefinitely. April 16.

6984. A. Vasarhelyi and J. Jambor. Preserving milk. April 2.

8882. W. P. Branson and H. W. Neild. Condensing milk or other liquids. April 9.

8963. T. Williams. Smoke-curing fish and flesh foods, and fuel compounds therefor. April 16.

9303. T. D. Constat. Preserves and condiments. April 9.

*B.—Sanitary Chemistry.*

1889.

6994. C. H. Harsey, for The Barry Patent Manure Company, Lim. Clarification or purification of sewage and other analogous foul waters. April 2.

1890.

2238. C. W. Doughty. See Class XV.

*C.—Disinfectants.*

1889.

8527. W. Black and W. L. Rennoldson. Preparation of disinfectants or anti-septics. March 26.

16,427. H. Staples, J. Staples, and W. Staples. Manufacture of a cattle cleanser, sheep dip, or disinfecting fluid. April 2.

## XIX.—PAPER, PASTEBOARD, Etc.

## APPLICATIONS.

4360. J. Robertson. Improvements in glazing paper and in machinery or apparatus therefor. March 20.

4914. W. Crosland. An improved method of graining or making a rough surface on paper. March 29.

4959. C. Kellner. Improvements in boilers for the manufacture of sulphide cellulose and in the method of heating the same. March 29.

4960. C. Kellner. Improvements in the process of and means for purifying paper pulp. March 29.

5053. C. Kellner. An improved process of softening brittle paper pulp, and apparatus therefor. April 1.

5128. C. Kellner. Process of modifying the properties of fibres used in the manufacture of paper. April 2.

5196. J. G. Walliker. Manufacturing bilge-shaped barrels from paper or other pulp. April 3.

5500. E. G. Wrigley. Improvements in the manufacture of absorbent sheets, rolls, or pads of paper, for blotting, filtering, and other similar purposes. April 11.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

5418. W. L. Wise.—From J. M. Badon. Transparent printed paper having the appearance of stained glass, and apparatus for manufacturing same. April 2.

5643. A. J. Boulton.—From Messrs. Jung and Lindig. Prevention of corrosion in vessels, tubes, valves, &c., used in the manufacture of sulphite cellulose. April 2.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES,  
AND EXTRACTS.

## APPLICATIONS.

4822. H. A. A. Dombrain. Improvements in apparatus for extracting fatty and other matters from substances by means of volatile solvents. March 27.

5366. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Production of guaiacol ether. April 8.

5367. H. H. Lake.—From W. V. McKenzie and H. J. Braker, United States. Improvements in refining apparatus for camphor or similar substances. April 8.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

6494. O. J. Steinhart. Manufacture of ethyl mercaptan. March 26.

1890.

1422. A. A. Vale.—From The Chemische Fabriks-Aktiengesellschaft. Process of manufacturing cumarone. March 26.

1583. S. Radlauer. Preparation of ethyl chloral urethane. April 16.

XXI.—PHOTOGRAPHIC PROCESSES AND  
MATERIALS.

## APPLICATIONS.

10,393A, 1889. J. S. Fairfax.—From F. Crane, United States. Improvements in the films or supports used for photographic negatives or prints. Previously included in No. 10,393 of June 26, 1889.

4606. J. Leslie. Improvements in the manufacture of transparent flexible films for photographic purposes. March 25.

## XXII.—EXPLOSIVES, MATCHES, Etc.

## APPLICATIONS.

4243. W. Schückher. Manufacture of grained smokeless explosive. Complete Specification. March 18.

4798. C. A. Burghardt. Improvements in the manufacture of nitrate of ammonium and of a resulting by-product. March 27.

4808. H. J. Haddan.—From E. Passburg, Germany. Improved vacuum drying apparatus for explosive substances. March 27.

5157. A. Noble and G. Stewart. Improvements in the manufacture of pellets or plungers for percussion fuses. April 2.

5209. H. H. Lake.—From H. S. Maxim, Austria. Improvements relating to the manufacture of explosives, and to apparatus therefor. April 3.

5292. W. C. Morison. Improvements in ammunition. April 8.

5364. J. R. France. Improvements in the manufacture of nitro-cellulose and apparatus for that purpose. April 8.

5376. H. de Chardonnet. Improved processes for the nitration and the denitration of cellulose, and for regaining the acids employed, and apparatus employed in connexion therewith. April 8.

5422. K. K. Malmström. Improvements in percussion fuses. April 9.

5535. R. Low. Improvements in percussion fuses. April 11.

5552. S. V. Dardier. Improvements relating to time and percussion fuses. April 12.

## COMPLETE SPECIFICATION ACCEPTED.

1889.

1884. P. Jensen.—From H. G. Underwood. Solidified pyrotechnic powders, and method of converting same into solid form for convenience in transportation, storage, and combustion. April 2.

## XXIII.—ANALYTICAL CHEMISTRY.

## APPLICATION.

4840. E. Chameroy. Improvements in apparatus for weighing and measuring the volume and density of bodies. Complete Specification. March 27.

# THE JOURNAL OF THE Society of Chemical Industry:

## A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 5.—VOL. IX.]

MAY 31, 1890.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers  
Single Copies (Members only) 2/6.

## NOTICES.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those Members of Council whose names are placed in italics in the annexed list will retire from their respective offices at the forthcoming Annual General Meeting.

Mr. E. Rider Cook has been nominated to the offices of President and Treasurer; and Sir Lowthian Bell, Bart., F.R.S., has been nominated Vice-President under Rule 11.

Mr. David Howard, Mr. B. E. R. Newlands, and Mr. J. C. Stevenson, M.P., have been nominated Vice-Presidents under Rule 8; and Mr. R. R. Tatlock and Mr. T. W. Stuart have been nominated Ordinary Members of Council under Rule 17, in the place of Mr. B. E. R. Newlands and Mr. J. C. Stevenson, M.P., nominated Vice-Presidents.

The Foreign Secretary has been nominated for re-election.

### ANNUAL GENERAL MEETING.

Notice is hereby given that the next Annual General Meeting will be held in Nottingham on Wednesday, Thursday, and Friday, the 9th, 10th, 11th July next.

The following is a synopsis of the arrangements:—

- Wednesday, July 9th.
1. Annual Meeting, University College - 11 a.m.
  2. Midland Railway Works, Derby; train leaves Nottingham - 1.10 p.m.
  - Or, Messrs. Morley's Hosiery Factory, Messrs. Turney's Leather Works, and Messrs. Blackburn's Hosiery Machine Works - 2.30 p.m. to 4 p.m.
  3. Conversation at Nottingham Castle - 8 p.m.

- Thursday, July 10th.
1. The Burton Breweries; train leaves Nottingham - 9.50 a.m.
  2. The Butterley Iron Company; train leaves Nottingham - 1.25 p.m.
  - Or, The Birks Company's Embroidery Works, Messrs. Manlove's Engineering Works, The Nottingham Company's Hosiery Factory, and Messrs. Dobson's Lace Factory - 10 a.m. to 11.30 a.m.
  - And The Corporation Gas Works, Messrs. Doughty's Lace Factory, and Messrs. Morley's Hosiery Factory - 2.30 p.m. to 4 p.m.
  3. The Dinner at the Exchange Hall - 7.30 p.m.

- Friday, July 11th.
- Excursion to Welbeck Abbey and Clumber; train leaves Nottingham - 8.40 a.m.
- Or, Excursion to Wollaton Hall and Newstead Abbey (if possible).
- Or, Messrs. Lambert's Lace Dressing Rooms, The Midland Lace Company's Frilling Factory, and Messrs. Lindley, Wright, and Cox's Lace and Hosiery Finishing Works - 10 a.m. to 11.30 a.m.
- Tickets of membership will be issued with the Ballot Lists in time for the meeting.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

#### LIST OF MEMBERS ELECTED, 23rd MAY, 1890.

- Aldrick, E. J., 15, Charles Street, Millwall, E., clerk in chemical works.
- Anderson, Eugene E. J., Gasworks, Maryhill, by Glasgow, assistant manager.
- Anderson, Wm. F., 20, Montague Road, Dalston, N.E., engineer.
- Barrie, Daniel McL., c/o Pollok Patents Gold Extracting Co., Ltd., Johannesburg, S.A.R., chemist.
- Benyon, Jos. A., c/o And. Allan, Ionontch, Montreal, Canada.

- Brasher, F. W., 20, Mainstone Terrace, Cattedown Lane, Plymouth, chemical engineer.
- Caldwell, H. M., 3, New North Road, Huddersfield.
- Chester, W. R., Gas Offices, George Street, Nottingham, gas engineer.
- Dudley, Dr. Chas. B., 1219, 12th Avenue, Altoona, Pa., U.S.A., chemist.
- Earnshaw, Edwin, 24, Mark Lane, E.C., accountant.
- Eastlake, A. W., Ropienka Oel Gruben, Post Olszanica, Galizien, Austria, petroleum works manager.
- Fergusson, J. Henry, 14, Batavia Buildings, Hackins Hey, Liverpool, director of gas company.
- Field, Walter D., Short Hills, N.J., U.S.A., technical chemist.
- Frankenburg, Alf., 62, Waterloo Road, Manchester, rubber works manager.
- Glen, Jno., jun., Glengowan Printworks, Airdrie, N.B., calico printer.
- Hedley, Jno., jun., c/o Coignet and Co., 150, Fenchurch Street, E.C., chemical merchant.
- Hodgson, Wm., Wheelgate, Malton, Yorks, manager Malton Farmers Manure Co., Ltd.
- Holloman, Fred. R., Sugar Refinery, Rawcliffe Bridge, Selby, Yorks, chemist.
- Laycock, Dr. W. F., Guncotton Works, Stowmarket, analytical chemist.
- Losanitsch, Prof. S. M., Belgrad, Servia.
- McLellan, Duncan, Annock Bank, Helensburgh, N.B., chemist.
- Moodie, Wm. E., Croftingea Works, Alexandria, N.B., analytical chemist.
- Moulton, G. J., Henderson Street, Macclesfield, manufacturing chemist.
- Reade, Thos., Oakleigh, Compton, near Wolverhampton, manufacturing chemist.
- Sanford, P. Gerald, c/o The National Explosives Co., Ltd., Hayle, Cornwall, chemist.
- Schofield, J. E., Old Street, Newchurch, near Manchester, assistant chemist.
- Stearns, Fred. K. (F. Stearns and Co.), Detroit, Mich., U.S.A., manufacturing pharmacist.
- Sutherland, J. A., 88, Gloucester Street, Glasgow, chemical works manager.
- Wachtel, Gregory, Elabonga, Government of Viatka, Russia.
- Wells, Jno., 33, Northampton Square, Clerkenwell, E.C.
- Whiteley, Jno. W., 210, North Hill Street, Prince's Road, Liverpool, chemist.
- Williams, Herbert C., Chemical Laboratory, Ruskin Road, Tottenham, N., chemist.

#### CHANGES OF ADDRESS.

- Archbold, Dr. Geo., 1/o West 14th Street; 7, Van Nest Place, Charles Street, New York, U.S.A.
- Bailey, E. M., 1/o Midcalders; Millbank Cottage, Uphall, N.B.
- Beringer, Cornelius, 1/o Camborne; 9, West End, Redruth, Cornwall.
- Buchan, Alex., 1/o Willowbank Crescent; 1, Carlyle Terrace, Cambridge Drive, Kelvinside, Glasgow.
- Buchanan, Josh., 1/o Glasgow; Poste Restante, Taltal, Chili.
- Burn-Murdoch, J. V., 1/o Boksburg; Botha's Reef Gold Mining Co., Ltd., Box 38, Krugersdorp, S.A.R.
- Dewey, F. P., 1/o Smithsonian Institute; Lanier Heights, Washington, D.C., U.S.A.
- Driffield, V. C., 1/o Farnworth; Appleton, Widnes.

Ellis, G. E. R., 1/o Montana; Nelson, Lake Kootanie, British Columbia.

Forth, H., 1/o Beech Avenue; 17, Herbert Road, Sherwood Rise, Nottingham.

Gregory, Wm., 1/o Walmer; Dover Place, Ashford, Kent.  
Griffith, Agnew, 1/o Southport; 28, Earl's Court Gardens, South Kensington, S.W.

Hanrez, P., 1/o Rue Moris; 188, Chaussee de Charleroi, Brussels.

Hardy, H. J., 1/o Greenwich; 163, Edmund Road, Sheffield.

Hart, Peter, Journals to 49, Faulkner Street, Manchester.  
Knight, A. H., 1/o Chapel Street; 34, Bentley Road, Prince's Park, Liverpool.

Leech, F. S., 1/o Loop Street; 39, Plein Street, Cape Town, South Africa.

Lovett, W. Jesse, 1/o Wakefield; 29, Brookland Street, Weaste, near Manchester.

Macdonald, P. C., 1/o Port Darwin; c/o A. Gallagher and Co., Post Office Chambers, Pitt Street, Sydney, New South Wales.

Macfarlane, R. F., 1/o Jarrow; Rio Tinto Co., Lim., Cwm Avon, Port Talbot.

Markham, A. D., 1/o Sutton; 2, Railway Terrace, Warrington, Surrey.

Moss, Jno., 1/o Thornton Heath; Clovelly, Norbury, S.W., and Wilson Street, New Cross Road, S.E.

### CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

*Chairman: David Howard.*

#### *Committee:*

<i>Sir F. A. Abel.</i>	R. Messel.
<i>H. E. Armstrong.</i>	R. E. R. Newlands.
<i>W. Lant Carpenter.</i>	B. Redwood.
W. Crowder.	T. Royle.
<i>W. J. Dibdin.</i>	John Spiller.
<i>C. Graham.</i>	Wm. Thorp.
S. Hall.	C. R. Alder Wright.
C. C. Hutchinson.	

*Hon. Local Sec. and Treasurer: Thos. Tyrer, Battersea, S.W.*

The names in Italics are those of members of Committee who retire at the end of the current Session.

The following have been elected to fill the vacancies and will take office in July next:—*Chairman: T. Tyrer; Secretary: T. W. B. Mumford; Committee: J. Dewar, A. G. Green, C. W. Heaton, D. Howard, W. S. Squire, T. E. Thorpe.*

#### SESSION 1889-90.

1890.

June 2nd:—Discussion on Messrs. Cross and Bevan's paper on the Chemistry of Hypochlorite Bleaching.

July 9th, 10th, and 11th:—Annual General Meeting in Nottingham.

*Meeting held Monday, 21st April, 1890.*

MR. DAVID HOWARD IN THE CHAIR.

### DISCUSSION ON MR. BOVERTON REDWOOD'S PAPER ON THE OIL-FIELDS OF INDIA.

(This Journal, April 1890, 359.)

THE CHAIRMAN considered that there could be no doubt as to the immense importance of the subject which Mr. Redwood had brought forward. The petroleum industry was so unmistakably one of the questions of the future, from many points of view, that it was a matter of the greatest importance to find our great Indian dependency so amply provided with this valuable product. It was to be hoped that these resources would be exploited with skill and energy, so that early and favourable results might be obtained. He was glad to see several gentlemen present who could speak with authority on the subject, and therefore would not further take up the time of the meeting himself.

MR. CHARLES MARVIN said that every one would, he was sure, concur with the remarks of the Chairman as to the importance of Mr. Redwood's paper. The Russian Government had some years ago published a bibliography of the various works dealing with petroleum. This bibliography was a bulky tome of some 300 pages, but the number of references to Indian petroleum that might be collected from the volume would not occupy more than two pages of the Journal of this Society. So far as he knew, no paper of importance dealing with the chemical aspect of Burmese petroleum had up to the present time been published in this country. All the more value, therefore, attached to Mr. Redwood's paper on the subject. The author had drawn the attention of the meeting to the four principal petroleum fields of India—those of Baduchistan, the Punjab, Assam, and Burma. He himself had always regarded the petroleum question from the political and popular point of view, rather than from the chemical. Regarded from that standpoint, it was interesting to note that Russia was developing railways on both sides of the Caspian which

## Death.

Joseph Jackson, Ashbank, Rudheath, Northwich.

would have to depend for fuel on the petroleum supply of Baku. Ten years ago the country east of the Caspian Sea was a prey to the man-stealing Turcomans. These had been replaced in power by the Russians, who had now a railway stretching for a distance of a thousand miles from the Caspian, which was consuming 10,000,000 gallons of liquid fuel a year from Baku alone. Such an immense consumption of oil from Baku for fuel purposes was due to the fact that the country traversed by the Merv railway was, like Badkhistan, almost devoid of coal and timber. That did not matter much so far as the Russians were concerned, because they had abundant supplies of liquid fuel to depend upon. The English, however, had nothing but the relatively limited supplies furnished by the Badkhistan region. As Mr. Redwood had pointed out, the Indian Government was engaged in carrying out boring operations there, but unfortunately the oil found was of such a character that it would not readily pass through the pipes, and was therefore troublesome to use as liquid fuel. He thought that the attention of the members of the Society might be advantageously directed to the problem of how to satisfactorily use this oil sludge for fuel on the Quetta railway, now running to within 70 miles of Candahar. Next in political importance came the oil-fields of Rawul Pindie, and those other northern fields to which the author had not referred, but which had been recently discovered, lying in the Waziri country, near the Khyber Pass. It was of course impossible to say what these oil-fields might yield; the present indications were very slight, but it was to be hoped that further investigation might prove that a copious supply was in existence there. Next to these two districts, which, as the meeting would see, were situated along the principal communications of India in the direction of Russia—from Quetta to Herat, and from Peshawur to Cabul, came the oil-fields of Assam. These also were of great political and commercial importance. For some time past the Government had been pushing a railway up the Brahmahpootra, and another up the Irrawaddy, towards the Assam frontier. Sooner or later there would be a connexion of the two railways in that quarter, and the petroleum fields of Makum would then be admirably placed for supplying fuel to that system of Indo-Burmese railways. After these in importance came the petroleum fields of Yenangyoung, which were exciting the greater amount of interest at the present time owing to the operations which were being carried on there by Messrs. Finlay, Fleming, and Co. He himself had long held the opinion that these fields would yield satisfactory results. As Mr. Redwood had pointed out, drilling operations had only been carried to a depth of 800 or 900 ft., whereas in the case of American borings 1,500 ft. was a common depth, and in many cases 2,000 ft. was reached. At such a depth as that, it was impossible to say what might be the yield of the Yenangyoung wells. As an illustration to support this opinion, he would remind the meeting of what had occurred at Baku. Professor Abich, one of the greatest geologists of Russia, visited that place when the drillers were commencing operations some years ago, and told them that it would be quite useless to drill below a certain point, because they would not find any oil in the lower strata existing there. The drillers disregarded his advice, and the result had been those enormous fountains of oil which were at present the wonder of the world. Mr. Redwood had given an immense amount of original information to the meeting, but, owing obviously to pressure of space, had omitted one point which seemed to him of such importance that he might perhaps be permitted to draw attention to it. It was this, that the crude petroleum of every country had its own special characteristics. The petroleum of the United States differed as much from that of Russia as the latter did from the petroleum of Burma. The oil of each country had its own special problems, requiring to be solved by the chemical expert. In the case of the United States, where the oil industry was about 30 years old, most of those problems had been overcome. The refiners there got the utmost possible yield of oil—results so exhaustive that until the Americans recently discovered certain extensive fields at Lima, Ohio, yielding petroleum of a sluggish character, not well adapted for lamp oil, they had no spare oil suitable for application as liquid fuel. The

petroleum of Russia was of an essentially different character, yielding a small proportion of illuminating oil, but large quantities of heavy lubricating oils. So far as Russia was concerned, the chemical problems connected with the oil supply had not yet been solved. She had one great chemical expert; he referred to Professor Mendeleeff, who had devoted a certain amount of scientific attention to the oil industry, but he was so much occupied with his professorial duties at St. Petersburg as to be unable to give the technical problems the requisite care at the refineries themselves. There were at present about 200 oil refineries at Baku, but the amount of chemical skill available for the industry being very limited, the refiners had so far devoted their attention to the task of merely extracting kerosene and overcoming the difficulties of transport, rather than to the solution of the problem of getting the largest possible results from their crude oil. In the case of the Burmese oils, apart from the local operations of Messrs. Finlay, Fleming, and Co., which had been of the most enterprising character, and the painstaking researches of Professor Dewar and Mr. Redwood at home, nothing had been done towards solving the problems connected with them. As Mr. Redwood had pointed out, those oils were of a peculiar character, and would require the most careful consideration of chemical experts in this country to render them of general commercial value. He felt sure that the admirable lecture to which they had listened would lead to many members of the Society taking a deeper interest in the subject. If they did, they would find that petroleum was undoubtedly one of the coming subjects of the future, and the study of it could not fail to lead to interesting and lucrative results.

MR. KIRKMAN FINLAY (of Messrs. Finlay, Fleming, and Co.) desired to thank the author and the speakers who had followed him for their kind remarks with respect to himself and his firm. It had afforded him and his partners great pleasure to add, in however small a degree, to the great store of knowledge possessed by Mr. Redwood with regard to the oil-fields of Burma. They felt strongly that it was better that the world should know the whole truth about those fields, and not be led away by irresponsible conjecture. Capital and knowledge were indispensable in conducting the enterprise there. If such were forthcoming the results would in all probability be satisfactory; if not, adventurers would be introduced and the results might be entirely different. It was their desire therefore to give the Society every information in their power with respect to these oil-fields.

MR. WATSON SMITH said that during the reading of Mr. Redwood's admirable paper it had occurred to him, as it apparently had also to the last speaker but one, that the commercial interest of this Burmese petroleum would depend to a considerable extent upon its containing considerable quantities of solid paraffins. The Caucasian petroleum was, he believed, very deficient in that class of hydrocarbons, whereas it now seemed that the crude petroleum of Burma was tolerably rich in them. It appeared to him that this Burmese petroleum was a kind of compromise, chemically speaking, between the crude American and the crude Caucasian oils. The fact called attention to by Mr. Redwood, of the close proximity of petroleum wells yielding oils containing high boiling and heavy hydrocarbons to others, the oils of which consisted of very light hydrocarbons of low boiling point, was of extreme interest, and seemed to him to present much that was suggestive. In Pennsylvania there were immense beds of anthracitic coal lying in close proximity to the petroleum springs and deposits. They now learnt that in Burma they not only had the petroleum wells, but, according to Mr. Redwood, large deposits of coal closely contiguous to them. He had awaited, during the reading of the paper, a statement of that fact, or the converse of it, and it just seemed to supply a missing link in connexion with the ideas already referred to, which had occurred to him. It would be of great interest to know whether this Burmese coal was, like that of Pennsylvania, of an anthracitic or even semi-anthracitic character. If so, the suggestion was that probably the petroleum was due to a slow kind of destructive distillation from these coal measures with subsequent condensation in contiguous

layers or strata of earth. Of course, in such case, in what particular strata the oils or crude products were deposited would naturally depend upon the physical condition of those strata as regards penetrability, &c. There was a further analogy which led one to believe in the probability as to correctness of this view, namely the fact that oils containing light products, as stated by Mr. Redwood, were found in close proximity to those containing heavy and high-boiling products. In that case also, one could imagine that subterranean heat, possibly resulting in emanations of steam or hot water, may have caused distillation of the heavier petroleum to take place, the lighter products of which, at first vaporised, would gradually and subsequently pass through and settle in the more impervious of the neighbouring strata, and there accumulate. But his theory might still hold good even if the Burmese coal only approached the anthracitic character, were, say, a slightly bituminous steam-coal, the distillation being then one of a less degree than that supposed to have occurred in Pennsylvania, though similar in character and effect. He might mention one fact which would be of interest in connexion with a slow distillation of petroleum oils. Those who had been practically engaged in the distillation of such oils might have observed, when employing ordinary glass retorts, that besides the usual distillation process there was a tendency to what he might term a "creeping over," due to capillary attraction. One could imagine it possible that this might afford an explanation of the passage of these light oils from the strata containing the heavier oils.

Mr. BOVERTON REDWOOD, in reply, said that he entirely agreed with Mr. Watson Smith as to the importance of the question whether these Burmese petroleum oils contained solid hydrocarbons in considerable quantity. He had already pointed out that a large proportion of the petroleum found in Upper Burma was of that class. He had indicated, further, that, according to information kindly given to him only that day by Dr. J. B. White—who, if he were present, would perhaps give the meeting the benefit of some further information—there was reason to believe that the petroleum now being obtained at Digboi would also be found to contain large quantities of solid hydrocarbons. With respect to the comparison made by Mr. Watson Smith between the petroleum of India and that of America, he thought it important to bear in mind that there was this fundamental difference between the two, that throughout India the petroleum occurred in the Tertiary formation, whereas in Pennsylvania, though not in California, it was found in the comparatively very old Devonian and Silurian formations. The speculation in which Mr. Smith had indulged with respect to the possible relations between petroleum and coal were of an extremely interesting character, and he hoped that Mr. Smith would pursue the inquiries he had suggested, and give the Society the results on some future occasion.

Dr. J. B. WHITE (Director of the Assam Railways and Trading Company) said, that in reply to Mr. Watson Smith's inquiry, he could state that the oil which they were now obtaining at Digboi contained a much larger proportion of solid paraffin than was formerly found in American petroleum. The specific gravity of the Assam oil indicated on Mr. Redwood's diagram was that of oil which had been exposed to the air for 10 or 12 years. He had himself taken the specific gravity of the oil from a flowing well some 17 years ago, and it was then  $\cdot 8683$ ; and he had no doubt that the oil now obtained was much thinner and would give a much larger proportion of illuminating oil than was yielded by the samples previously sent over for examination. As to the question which Mr. Smith had raised with respect to the distance of the oil deposits from the margin of the great coal-field, he might say that in Assam, generally speaking, it lay all along the coal-field for a distance of about 120 miles. So far, however, from being of the anthracitic character which Mr. Smith had suggested, the Assam coal was decidedly bituminous, closely resembling the coal of South Wales—so closely indeed, that it had driven South Wales coal out of the Calcutta market. They had no coal resembling anthracite in Assam, and he had reason to believe that there was nothing of that kind in

Burma either. He could not sit down without thanking Mr. Redwood for the very able paper which he had read, and which he hoped would have the effect of directing attention to the immensely valuable deposits of oil which undoubtedly existed.

Mr. BOVERTON REDWOOD hoped that he might be allowed to make a few further remarks with regard to the question of the specific gravity of Assam oil raised by Dr. White. He might mention that within the past 10 or 12 years he had had to examine samples of that oil submitted by the Assam Railways and Trading Company, of which Dr. White was a director. He understood that the samples were obtained from surface collections, and he had no doubt that oil obtained from a fresh-flowing well would be found to be of far lower specific gravity. So far as he knew, the only samples which had come to this country were those which he had analysed and had been kindly permitted to refer to in his paper. He hoped shortly, however, to have an opportunity of examining the oil obtained from the well at Digboi, and might perhaps be able to supplement his remarks of to-night by giving the results obtained.

#### NOTE ON THE EXPULSION OF AMMONIACAL COMPOUNDS FROM SULPHURIC ACID USED IN KJELDAHL DETERMINATIONS.

BY E. R. MORITZ.

SOME time ago, in conjunction with Professor Meldola, I communicated to this Society\* a method for the freeing of the sulphuric acid used in the Kjeldahl method from the ammoniacal compounds which are apt to be contained in it. This method consisted in digesting the acid with a small proportion of potassium nitrite. Shortly after its publication Professor Lunge criticised it adversely,† contending that the nitrous acid would not be completely expelled owing to the formation of nitroso-sulphuric acid; and, further, that the nitrous acid locked up in this way would seriously interfere with the accuracy of any Kjeldahl determinations which might be made with the sulphuric acid so treated. Lunge bases these views upon the results of experiments in which the amount of nitrous acid remaining in the acid after digestion with nitrite was estimated by potassium permanganate. He finds this acid retained by the sulphuric acid to equal approximately 95 per cent. of that originally added. It was our intention to go over the ground immediately after the publication of Lunge's criticism, but the pressure of many and more immediately important duties has prevented us from doing so until quite recently. Although Professor Meldola has left the recapitulation of the work in my hands, it has been submitted to him from time to time; and I may add that he endorses all that now follows.

I do not deny that nitroso-sulphuric acid is formed during the treatment of the sulphuric acid with the nitrite, but I argue that this is a matter of no moment so long as the compound is broken down and the nitrous acid expelled before the digestion is completed. The experiments which follow show, I think, that such is the case:—

Experiment 1.—0.3 per cent. of ammonium sulphate was added to pure sulphuric acid. The above acid was then digested with potassium nitrite; after digestion it gave no reaction (after neutralisation and dilution) with Nessler solution, and no reaction (after dilution) with starch and potassium iodide.

Experiment 2.—The same acid as above was digested with potassium nitrite (0.05 grm. per 10 cc.). After digestion the residual nitrous acid was determined by potassium permanganate. The sulphuric acid was found to contain 0.0008 grm. nitrous acid per 10 cc.

\* Journal of the Society of Chemical Industry, Vol. VII., p. 63.

† Zeits. f. angew. Chem. 1888, No. 23.

Experiment 3.—The same acid, after similar digestion, was used as in an ordinary Kjeldahl estimation, pure cane sugar being the substance operated upon. The nitrogen calculated upon 100 parts of cane sugar was 0.01 part.

Experiment 4.—The same acid, after treatment with potassium nitrite, was used as in an ordinary Kjeldahl determination, urea being the substance operated upon. The same sample of urea was also subjected to another Kjeldahl determination, pure sulphuric acid being used. The following results were obtained:—

—	Theory.	Pure Acid.	Treated Acid.
Percentages of nitrogen .....	45.67	46.38	46.38

Experiment 5.—A set of determinations were then made as described in Experiment 4, uric acid being substituted for urea. The following results were obtained:—

—	Theory.	Pure Acid.	Treated Acid.
Percentages of nitrogen .....	33.33	33.77	33.71

Experiment 6.—A sample of malt extract was now analysed by Kjeldahl's process, both with treated acid, and with some pure acid.

—	Treated Acid.	Pure Acid.
Percentage of nitrogen .....	1.09	1.11

The above experiments show, I think, that the treatment suggested is competent to free the acid from combined ammonia, while no nitrous acid remains in the sulphuric acid to interfere with the accuracy of Kjeldahl determinations subsequently made with it.

I must add, however, that I have come across cases where the whole of the nitrous acid was not expelled in the time originally suggested (two hours), owing probably to insufficiently high temperature of digestion or other accidental causes of that kind. But as it is exceedingly simple to test each batch of acid for nitrous acid before employing it as an analytical reagent, this constitutes no practical argument against the process originally suggested. For if the nitrous acid is not completely expelled in the time suggested, the digestion can be continued until the whole of the impurity is found to have been removed.

I may add that the acid used in the foregoing experiments was digested in beakers covered with clock glasses, 0.05 grm. of potassium nitrite having been added to each 10 cc. of previously ammoniated acid.

I have to thank my assistant, Mr. H. T. Pentermann, for carrying out the above experiments.

#### DISCUSSION.

The CHAIRMAN said that only those who had tried the experiment knew how difficult it was to get pure sulphuric acid; whereas in the Kjeldahl determination absolute purity was required. Therefore this paper was of great practical importance. The smallest traces of ammonia would entirely vitiate the results of the process; and it would appear that Dr. Moritz had clearly made out that Professor Lunge's objection to the use of nitrites in purifying the sulphuric acid must be based on the results of an imperfect boiling. The presence of ammonia or nitrate was alike objectionable; but in this case, if proper precautions were taken, there appeared to be no danger of either. If any members present had had experience of the process, he would be glad to hear their opinion on that point.

Dr. J. W. LEATHER had had no difficulty in obtaining pure sulphuric acid straight from the dealers, and therefore did not see the use of trying to purify impure acid. He got pure acid at a nominal price, something under 8d. a pound, it having become much cheaper recently.

Mr. BERTRAM BLOUNT wished to point out, with regard to the temperature needed to effect a complete decomposition in the Kjeldahl process, that the advantage of using a high temperature lay in the fact that the decomposition of the substance was thereby rendered more perfect. According to a private communication made to him, such a temperature could be readily obtained by adding to the sulphuric acid a suitable proportion of potassium sulphate. Acid potassium sulphate was formed, which body, having a higher boiling point than sulphuric acid, caused the organic substance present to be decomposed more completely than would otherwise be the case.

Mr. W. FOSTER would like to ask whether there was any limit to the use of Kjeldahl's method for the estimation of nitrogen. It had occurred to him recently to use the process, and he had not found it to answer as he expected. In the case of the hard cokes left after the destructive distillation of organic bodies, such substances were not attacked by strong sulphuric acid in such a way as to warrant him in considering the results good. He would be glad to know, therefore, whether any other member had used the process for such purposes. For soft substances, the method seemed to him to be well adapted; but he wanted to know how it could be applied to such bodies as were generally got by the destructive distillation of such substances as petroleum, for instance. He believed that a paper had recently been read upon the subject by a German chemist whose name he could not for the moment remember, and he thought that there must be some modification of the method for dealing with hard substances such as he had mentioned.

Mr. E. J. BEVAN said that in reply to the question put by the last speaker, he would suggest that the use of Nordhausen acid might perhaps get over the difficulty. Mr. Cross and he had devised a process for the estimation of carbon by digesting the carbon compound with sulphuric acid and chromic acid, and measuring the mixture of carbon monoxide and dioxide evolved. In the case of coals, when ordinary sulphuric acid was used no action took place, but with Nordhausen acid a considerable amount of the mixed gases was given off.

Mr. W. FOSTER explained that the cokes to which he had referred were so hard as not to be easily attackable under any circumstances, and certainly Nordhausen acid would not attack them—at least the action appeared to be very slow. The cokes were in the finest state of division. Nordhausen acid had always been used, and, in some instances, potassium permanganate had been finally added in small quantities.

Mr. BERTRAM BLOUNT suggested that in such case Mr. Foster might find that potassium sulphate would answer the purpose.

*Meeting held on Monday, May 5th, 1890.*

MR. DAVID HOWARD IN THE CHAIR.

#### THE CHEMISTRY OF THE DINSMORE PROCESS FOR THE MANUFACTURE OF COAL GAS.

BY WATSON SMITH,

*Lecturer in Chemical Technology in University College, London, &c.*

At a meeting of the Liverpool Section of this Society, held December 4, 1889, a paper was read by Mr. Isaac Carr, in which a description of the plant was given as well as the general *modus operandi* for carrying out the Dinsmore

process. For this I will refer you to this Journal, 1889, 960—962. Mr. Carr there makes good his claims for increased luminosity whilst using inferior species of coal not usually employed in gas-making, such as Arley coal, mingled with 25 per cent. of its weight of Arley slack. These claims as regards increased luminosity were supported by the experiments of Mr. Wm. Foster, M.A., of Middlesex Hospital. However, the statements as to the quality of the tar products were somewhat vague, and rumours got abroad of a rather sensational character, either as to failures of supply or failure as to quality of coal-tar, if this process were generally adopted. In order to combat these notions, and also to ascertain the condition of the coal tar produced, I undertook for Mr. Carr and the Widnes Gas Company an investigation of the tars produced at the works of this company, of which Mr. Carr is the manager. My results were communicated to a meeting of the Manchester District Institution of Gas Engineers on March 1st, and appeared in the "Journal of Gas Lighting," of March 11, 1890, 436—440. Since this I have tried certain experiments with the view of ascertaining some of the conditions under which the constituents of vaporised tars may undergo transformation, and what the nature of such transformation is, and the results I hope to lay before you this evening.

The Dinsmore process, as modified by Mr. Carr, consists in subjecting coal to a kind of double destructive distillation, the first operation being to carbonise the coal and produce gases and tar vapours; the second to further transform some of the constituents of the tar vapours into a sufficiently permanent illuminating gas, besides furnishing to the gas of the first heating a certain quantity of highly illuminating vapour, which may raise the total illuminating value by several candles. The question will be asked, and was asked at Liverpool, when Mr. Carr read his paper, "Has not this been done before?" I may reply, "It has all been tried before, but certain insuperable difficulties remained which hitherto had prevented success." It remained for Mr. Isaac Carr to engraft upon the best that had been so far done in this direction, in short, upon the Dinsmore process as it was, one or two apparently trivial improvements, to give rise to the Dinsmore process as it is. It may be instructive to go back to one of the earliest recorded attempts to subject coal to such a double destructive distillation as that referred to. This I find was in the year 1830, when James Down (Eng. Pat. 5966) patented a process of which the following is an abstracted record, his object then being to convert tar into gas, since tar was almost a valueless substance, if not a nuisance. The patentee made or generated gas out of certain portions of the "residuum" by passing crude or "nascent" gas with its vapour of tar and ammonia through a long stratum of ignited charcoal or coke, thereby evolving an additional quantity of gas free from the impurities "of the said nascent gas." A kind of box with divisions in it, which would stand the heat well, was arranged, and nearly filled with charcoal or coke, and connected with the ordinary retorts. The idea was to furnish a long stratum of ignited charcoal or coke, and the containing partitioned box was to be set like an additional retort, and to be fired with the waste heat of the other two ordinary retorts from one and the same furnace set below these. Down does not claim increased illuminating power, but merely says he thus does away with the necessity for a separate purifying apparatus. No doubt he also very much desired to consume as much as possible of his tar in the process.

In 1850, Michiel (Eng. Pat. 13,066) proposed to collect the tar and then feed it by a pipe into a hot retort or other heated vessel, in order to gasify it. He proposed to let in half a gallon of tar per given period of time, indicated for the workmen by an index; and in this manner he would work it all up. These are two of the most reasonable processes patented at the earlier dates.

I consider the earliest one, *viz.*, that of Down, an admirable conception in theory, though absolutely unrealisable in practice on the lines laid down by that inventor, for the divided box would most certainly be stopped up with thick pitch, sooty matter, and possibly coked or semi-coked pitch, and probably after one working of the retorts.

In the original Dinsmore process it was, I believe, proposed to run in tar to the retorts, and the result was then

obstinate stoppages in the ascension pipes from the ducts. So that the Dinsmore process, until modified by Isaac Carr, was by no means a success.

Carr's modifications consist, in the first place, in such a setting and arrangement of the extra heating apparatus termed the duct, that the heat applied is not excessive, and is, moreover, a graduated heat, strong as the crude gas enters, and less strong as it reaches the ascension pipe. The ascension pipe is, moreover, surrounded by a water-jacket, the effect of this cooling arrangement being to prevent the excessive charring and pitch-formation, otherwise causing the choking-up of this pipe. But just below this ascension pipe is a vertically descending pipe, leading from the duct downwards, so that any pitch formed in the duct and ascension pipe can run down towards this outlet, and, descending by it, slowly ooze out below the surface of water by which the extremity of the pipe is sealed. It is on these last-named devices by Isaac Carr that, in my opinion, the whole success of the Dinsmore process depends.

More recently, Mr. F. Pritchard, manager of the gas works of the Huyton and Roby Gas Company, near Liverpool, has made a further addition by a modification of the duct E. (Compare ducts E, E, Figs. 2 and 4.)

In connexion with and intersecting the ascension pipes is a collecting chamber D (Fig. 3), uniting together the various retorts of each bank, and fitted with valves C, to prevent back-flow of gas from the other retorts when any one of the bank is being separately drawn and charged. (See also Fig. 1.) The end of the collecting chamber is connected with the duct E, which is made of cast iron, and fitted with a cast diaphragm or midriff E, (Fig. 1), cast in solid, and running to within 8 inches of the far end of the duct. The gas thus passes along the under side of the diaphragm, up the space at the far end, along the top side, and through the water-jacketed ascension pipe G, to the hydraulic main. A temperature of from 700° to 800° F. is found to yield the best results in the iron duct, whereas in the fire-clay duct double that temperature is necessary. Since only such a low heat is used, the life of the duct will be probably of many years' duration. It is estimated that the cost of applying the system to existing systems of through-retorts is about 6*l.* per mouthpiece. It is found necessary to open the duct once a day, to remove the pitch which condenses in and runs down the water-jacketed pipe, and for this purpose a valve C, separating the duct from the collecting chamber, is closed, the gas meanwhile passing to the hydraulic main in the ordinary way, by the ascension pipe, with small dip pipes at J, leading direct from the retorts. There is a heavier seal on these pipes than on those leading from the duct at G to the hydraulic main.

Now, when I have recounted all these precautionary arrangements to prevent stoppages, even when using a duct heated only to dull redness, you may well imagine what the fate of a process in which Down's earlier apparatus was used would be.

That water-jacketed ascension pipe looks like a daring adventure, but it is really very ingenious, and scientifically correct. That which usually collects in the ordinary ascension pipes is what may be termed semi-coked pitch, a something between pitch and gas-coke, or pitch much thickened with soot. The water jacket, with water entering cool and escaping boiling, causes condensation of a little more tarry matter than would otherwise separate, and this, so to say, reduces the melting point of the whole, which consequently keeps "on the move" downwards, and so, slowly but continually, slides down into the duct, or, at all events, keeps the ascension pipe open to the gas current. The duct consequently plays, in the Dinsmore process, not only the part of a carburetting apparatus, but also a part precisely analogous to that of a dust-chamber; it is a "pitch-chamber," as well as a carburetter.

Now, with regard to the capacity as a pitch collector or chamber, the function of the duct is a mechanical one and readily comprehensible, but the case is different when we regard it as a carburetting apparatus, as an instrument for increasing the luminosity and, to some extent, the volume of the gas.

As regards actual increase of illuminating power, there can be no question after the exhaustive tests and determina-

tions of Mr. Wm. Foster, M.A., and later by Mr. Francis Jones (this Journal, 1889, 961). Mr. Francis Jones finds a larger quantity of acetylene in Dinsmore than in ordinary gas. The prolonged heat probably accounts for the reduction of olefiant gas to acetylene, as well as the formation of the latter by other modes. Now, seeing that there is some increase in volume, and certainly an increase in illuminating power, it would seem that certain hydrocarbon constituents of the gas are broken up into less luminous constituents, which swell the volume to the decrease doubtless of illuminating value, while certain constituents of the crude gas otherwise condensing to form tar, are also decomposed to yield highly illuminating compounds retaining the gaseous form, in contact with so large a volume of permanent gases. But the puzzle has been this, that hitherto gas manufacturers and chemists have been assuming that continued high temperatures in the retorts whilst decomposing and breaking down hydrocarbon substances, generally separating some carbon, of necessity must give rise to bodies of less and less illuminating value as the decomposing and disrupting action goes on, and now Mr. Carr, with the Dinsmore process, succeeds in *doing both*, namely, breaking down with increase of volume and diminution of illuminating power, and at the same time adding illuminating power, derived from the tar vapours, over and above that lost in increase of volume. Before proceeding to show how this is quite possible, let us inquire into the condition of the tar produced in the Dinsmore process, for, by subjecting crude gas, which includes the tar in the state of vapour, to continued high temperatures, it may be confidently expected that the resulting tar, which is condensed, will bear its own testimony. I have analysed two samples of tar from the Widnes gasworks, of which Mr. Carr is manager, that marked A. being actual, or, as it is termed, surplus Dinsmore tar, and that marked B. being ordinary tar, containing  $\frac{1}{3}$ rd of the Dinsmore product.

	A.	B.
	Surplus Dinsmore.	Ordinary Tar. ( $\frac{1}{3}$ rd of Dinsmore.)
	Per Cent.	Per Cent.
Water .....	1.1	7.1
Light oils .....	1.3	5.4
Creosote oils .....	16.5	17.8
	(rich in naphthalene.)	
Anthracene oil .....	12.1	8.6
Pitch .....	63.0	61.1
Specific gravity of the two tars .....	<div style="display: flex; align-items: center;"> <div style="font-size: 3em; margin-right: 10px;">}</div> <div> A .. 1.157 B .. 1.150 </div> </div>	

**The Creosote Oils.**—These contain somewhat over 50 per cent. of naphthalene. The specific gravity of the oils after the separation of naphthalene:—A. = 1.030; B. = 1.025.

**Carbolic Acid.**—This, as is usually the case with tars very rich in naphthalene, as, for example, the London tars, is chiefly found in the creosote oils. The light oils were also extracted. A. contains 2.5 per cent., B. contains 5.4 per cent. of crude carbolic acid.

**Anthracene.**—A. contains 0.79 per cent., B. 0.32 per cent. of real anthracene. The anthracene from A. was obtained without any coking of the pitch; that from B. after incipient coking.

The results were quite what I expected to find. It is clear that the phenols (see analysis of A., carbolic acid) have been drawn up in the extra-destructive distillation process. It is also probable that the increase of anthracene is at all events in part due to the reduction of higher phenols, and it must be remembered in this connexion that Noelting has discovered the phenols both of anthracene and phenanthrene in coal-tar heavy oils (this Journal, 1884, 234). The benzene in A. has been doubtless considerably

drawn upon along with others of the benzene hydrocarbons, by the gas produced, to the increase of its illuminating power.

It is clear that A. as a tar is very little behind B. in point of value. The lower specific gravity of B. than that of A. indicates what is really the case, viz., that B. is richer in naphthalene than A., and contains less crude anthracene. The light oils from A. and B. gave the following results on distillation:—

LIGHT OILS.  
(Per cent. by volume.)

	A. (Sp. gr. = 0.930.)	B. (Sp. gr. = 0.923.)
Below 100° .....	4	4
From 100°—120° .....	11	11
„ 120°—130° .....	16	14
„ 130°—150° .....	20	27
„ 150°—175° .....	18	150°—180° .. 24
„ 175°—195° .....	14	180°—185° .. 7

Residue = solidified naphthalene.

The best criterion for the tar distiller as to how far the distillation must be driven to obtain such results as those given, is to be found in the quality of the pitch left behind as residue.

The pitch from A. and B. was tested, and found to be good hard pitch.

PITCH.

Action of heat {	Softens at 67½° C.	68° C.
	Twists „ 71½° C.	72° C.
	Melts „ 94° C.	95° C.

I may mention that other samples of Dinsmore and ordinary tar from the Widnes works were also tested by Mr. W. R. Chester, manager of the gasworks of the Corporation of Nottingham, and our results were mutually confirmatory.

Some interesting results were obtained with a sample of tar taken directly from the Dinsmore duet at a temperature of about 350° F. The specimen contained no first and scarcely any of the second light oils. These must have been carried forward, and only condensed further on. What was actually condensed was a product containing a very large quantity of anthracene, with scarcely any naphthalene. Now, naphthalene is generally looked for in such high-boiling tars, but doubtless this hydrocarbon had been nearly all carried forward by the hot gas and vapours, the less volatile crude anthracene remaining behind. The remarkable thing is that amongst the anthracene oils was a large proportion of phenols with carbolic acid, showing that crude phenol and cresol will condense at a temperature at which naphthalene is carried forward in the state of vapour, if in addition to heat there be a current of gas. In this tar there were 2.8 per cent. of water; light oils, nil; heavy oils, only 1.7 per cent.; creosote oil, 14.6 per cent. (sp. gr. 1.04); anthracene oil, 25.9 per cent.; pitch, 55 per cent. The amount of crude carbolic acid was extraordinary, viz., 5.1 per cent., and it was contained chiefly, as stated, in the anthracene oil.

With regard to the tar obtained when a duet is used like that devised by Mr. Pritchard, in which the gas has to pass over a still greater heated surface, I have tested a small sample of such tar and found it of good average quality.

# THE DINSMORE PROCESS.

Fig. 1.

Fig. 2.

THE DINSMORE PROCESS.

Fig. 3.

Fig. 4.

Having given a fair notion of the character of the tar produced by the Dinsmore process, I must only add that the coal used by Mr. Carr was not the usual gas coal, or Lancashire cannel, but a common steam coal from the St. Helen's district, ordinarily yielding about 9,000 cubic feet of 15-candle gas. By the use of this coal in the Dinsmore process Mr. Carr produces 9,800 cubic feet of from 20 to 21 candle gas. It may not be known to many present, and so I will just mention the fact, that it is now pretty accurately ascertained that the celebrated Lancashire cannel coals, such, *e.g.*, as Wigan cannel, are getting near their end, and consequently begin to rise in price. This is a very cogent reason alone for the energetic way in which the Dinsmore process has been perfected and pushed forward.

Proceeding now to the chemical changes taking place in the Dinsmore duct, let us ask, "What are the results of a prolonged red heat on the vaporised products of the gas retort?" The direction, it may be replied, is one and the same in all cases, with but few exception, *viz.*, to the decomposition or resolution of the more complex hydrocarbons or carbon compounds into less complex and more simple forms, the extreme limits being carbon (soot, coke), carbonic oxide and hydrogen. This final ideal stage is never fully reached, of course, and yet to some extent and in some degree it is, for the products named are always present, and increase with increased heats; and there are some carbon compounds more easy of such ultimate resolution than others. The paraffins may suffer resolution and yield olefines and hydrogen, and these again may be further reduced to acetylene and hydrogen. Mr. Francis Jones found in the Dinsmore gas about 0.14 per cent. of acetylene, and he adds that the acetylene in the gas of the Manchester Corporation does not exceed 0.05 per cent. Acetylene being an illuminating constituent, this is a point favourable to the Dinsmore gas; but whilst no doubt its greater quantity is due to the prolonged heat in the duct, yet it may also be due in part to the class of coal carbonised. But let us once more regard the acetylene which Francis Jones finds present to an extent nearly three times that usual in ordinary gas. Berthelot has shown that when heated in a glass tube to dull redness, it is converted into benzene,  $3 \text{C}_2\text{H}_2 = \text{C}_6\text{H}_6$ . It also plays an important part in the formation of toluene, the xylenes, and probably of anthracene. Now when we regard the tar analyses we observe the diminution of the phenols in the Dinsmore tar, besides that of the first light oils containing the benzenes. Let us now ask, what becomes of the phenols which have vanished from the Dinsmore tar? Experiment has proved that phenols may be reduced, either alone, to form the corresponding hydrocarbons, or in conjunction with certain non-saturated hydrocarbons to form aromatic hydrocarbons of more complex types. The Dinsmore duct we may consider as a red-hot tube lined with carbon in a finely divided, or at all events porous form, and the crude gas itself, as it comes from the retorts, as filled with a vapour of finely divided carbon or sooty particles. The duct thus serves to prolong the contact of the red-hot carbon with the constituents of the gas. I have proved by actual experiment that when pure carbonic acid vapours are passed through a red hot glass tube containing iron turnings, or carbon, the result is the same, *viz.*, reduction to benzene is effected, according to the equation—

In fact this is the most convenient way, I know, for preparing pure benzene free from thiophen for lecture experiments, and I have long used it. Cresol in like manner yields toluene. I have also tried the experiment of passing a mixture of carbonic acid vapour and carbonic oxide through a red-hot tube with pumice stone, and I found scarcely any action to take place, whilst with a mixture of hydrogen gas and carbonic acid or cresol, reduction takes place at a high temperature with formation as with carbon, of benzene or toluene, as the case might be. Tervet has shown that the last gaseous products yielded by the almost exhausted fuel in a gas retort, consist of nearly pure hydrogen. He patented a process for increasing the yield of ammonia from the coal being carbonised in the gas

retorts. He proposed to turn the final products of a finishing retort consisting mainly of hydrogen into a retort which had been charged and working for about an hour, and thus by supplying hydrogen at the right period, he claimed an increased production of ammonia, and, indeed, he proved by experiment that this increase is an undoubted reality (this Journal, 1883, 445—449). If, then, the retorts in the Dinsmore process are worked consecutively through the duct, we should have along with the usual average gas from one retort, the finishing gas of the other retort (if two were working through one duct). The hydrogen at the high temperature would then certainly reduce phenols to great advantage. I am informed that the retorts are thus worked consecutively. Again, crude phenol (phenol and cresol) may contribute to form anthracene. Köhler has proved this (this Journal, 1885, 335). Probably in this reaction two molecules of cresol and one of phenol interact:—

Finally, it will be observed that an essential difference between the ordinary gas process and the Dinsmore process is that in the ordinary case we have each retort acting independently and discharging independently its issues into the hydraulic main, where, of course, no further chemical change in the gases can be expected to occur; but in the Dinsmore process we have the final issues (hydrogen) of one retort mingling in a red-hot pipe with the earlier issues of a neighbouring retort, and we have now seen that under the circumstances interaction may take place. The latter slightly- or non-luminous constituents of the finishing retort thus enrich themselves and become carburetted.

#### DISCUSSION.

The CHAIRMAN said that the chemistry of gas manufacture was apparently an inexhaustible field of interest. Whether the total destruction of benzol and toluol was desirable was, however, a serious question, upon which the Dye Industry would have something to say. Papers of the nature of that just read by Mr. Watson Smith were specially valuable as indicating to gas engineers the conditions under which they can produce such constituents as might be required at the moment. At one time the demand might be for hydrocarbons for use in various industries, at another the chief object would be to produce as much gas and as little of by-products as possible. Mr. Foster being present, would, he hoped, give the meeting the benefit of his wide knowledge and experience of this subject.

Mr. W. FOSTER said that he was glad of an opportunity of explaining certain proceedings on his part which, as Mr. Watson Smith had observed, had given rise to some comment. In November 1889 he visited Widnes to report on the character of the gas then being made by Mr. Carr. The table before the meeting\* was prepared by him for the purposes of the paper read by Mr. Carr at Manchester. Nothing was said on that table as to the illuminating power of the gas under notice, but the point was fully gone into at the time, and was embodied in the original report. He was at Widnes for four days, and spent the whole of the time with Mr. Carr at his works. He wished to explain, however, that he was not able to go fully into the question of the tar at the time, though he took samples of tar both from the Dinsmore duct and the works main, each of which was examined and the results incorporated in his report, a further description of his results and his own opinions being expressed in a discussion at Manchester on the reading of Mr. Carr's paper. On the termination of that discussion his obligation to the Dinsmore Company was discharged. A point about the Dinsmore process as practised at Widnes which struck him as specially admirable was that one retort of a bed of six was drawn and charged hourly. Each retort

\* See this Journal, Dec. 1889, 961, 962.

was heated for six hours, and during all that time gases were coming off in the different phases of destructive distillation and commingling in the central chamber or duct. When the workmen wanted to discharge a retort, all that was necessary was to turn a special tap, thus shutting off that retort from the duct and causing the gas, when the lid was again closed, to pass into the ordinary hydraulic main. The gas was never subjected to the action of water in the hydraulic main except during the few minutes occupied in taking out the coke and putting in the coal. That was a most important feature of the process, and required emphasising. (The speaker here entered into a description of the manipulation of the apparatus illustrated by the diagrams.) The gas made by the Dinsmore process at Widnes was decidedly richer in heavy hydrocarbons than gas made in the ordinary way from such coal, and from a chemical point of view was altogether better as an illuminating agent. The particular coal employed during his experiments was Abram Arley Mine slack, a cheap coal which would not ordinarily produce the quantity of gas which he had found it to produce by this process, the illuminating power of the gas being at the same time several candles higher. When his results became known, some gas engineers shrugged their shoulders. They held it impossible to heat coal gas without impoverishing it, because so many people had tried to do so before and failed, and in this respect, speaking broadly, such a view was correct. But the Dinsmore process in operation at Widnes consisted in heating for a limited period a stream of crude coal gas laden with tar particles and heavy hydrocarbon vapours, the latter of which were capable of being further decomposed by the action of heat. He had had this question before him in another form for years, and the thing was perfectly intelligible. In examining very rich coals (say from Kentucky), which were so rich as to be incapable of being distilled for gas by the ordinary apparatus, either larger surfaces or increased temperatures were necessary for fully developing the gas-producing qualities which they possessed. His experiments at Widnes had fully borne out Mr. Carr's assertions. That he did get more gas was verified by the measurements. The plant and everything connected with the process was thrown open to those who cared to see it, and there were absolutely no secrets about the matter. Moreover, the illuminating values as stated by him were fully borne out by the complete chemical analyses of the samples. He attached considerable importance to these figures because they had been arrived at after very long experience. (The speaker here referred in detail to the table of analyses, and showed that the results brought forward by Mr. Watson Smith were in accord with his own original report.) But there was one point about the experiments that was questioned, and very properly so, and that was the extreme lowness of the specific gravity. Nobody had yet accepted those figures as exact without reserve, and they were still under surveillance. It was, however, not his business to write history, but to try to make it; and he had therefore left the gas engineers to dispute over this matter among themselves. He had been taken to task because his observations on specific gravity and illuminating power were not in accordance with statements in the text-books. He would leave the engineers to settle that point, merely observing that the only way in which they could properly do so was to bring forward actual experiments proving the opposite. Having dealt with many sorts of coal, and finding that by means of high temperatures he could split up the tars, Mr. Carr's results were quite intelligible to his mind. Given a coal, the amount of tar would vary, and in such cases the amount of gas would vary also. Where there was more gas there would be less tar, because the amount of coke was found to be a pretty constant quantity. That had been shown over and over again. In the case of the carbohydrates, matters were not so simple, because the amount of coke was much smaller; but with ordinary coal the coke was fairly constant and the changes were rung on the tar. Supposing a hydrocarbon like ethane were decomposed by heat, thus  $\text{C}_2\text{H}_6 = \text{C}_2\text{H}_4 + \text{H}_2$ . The two volumes of the ethane furnished two volumes of ethylene and two volumes of free hydrogen, the total lighting efficiency of the new bodies being greater than that of the old. Further,

it was known that marsh gas was of itself non-luminous; yet if the amount of air supplied to it during combustion were modified it became luminous. The luminosity could only be explained on the assumption that free carbon or hydrocarbon vapours were produced. It was difficult to prove the production of these hydrocarbons, but nevertheless he believed it was a fact. So it was with other bodies. Therefore if marsh gas, which was a saturated hydrocarbon, could thus be made to yield a luminous flame, it might be inferred that it was due to the temporary production of other hydrocarbons presumably unsaturated. He would point to an equation illustrating this assumption. If they took marsh gas,  $\text{CH}_4$ , they might, hypothetically, suppose acetylene,  $\text{C}_2\text{H}_2$ , to be produced. Thus,  $2\text{CH}_4 = \text{C}_2\text{H}_2 + 3\text{H}_2$ . Marsh gas, as he had said, was non-luminous, but was rendered luminous by the least trace of acetylene. So that if by the Dinsmore or any similar process acetylene were produced, each four volumes of marsh gas would give two volumes of acetylene and six volumes of free hydrogen, not merely an increase in volume, but the communication of illuminating power to that which was previously non-luminous. Dr. Percy Frankland had determined the lighting values of the paraffin  $\text{C}_{10}\text{H}_{22}$ , and also of the olefine  $\text{C}_2\text{H}_4$ . The speaker thought it desirable to coin an expression for such lighting values, and therefore preferred the expression "specific illuminating power" of a given substance. The specific illuminating power of ethylene ( $\text{C}_2\text{H}_4$ ) was much greater than that of ethane,  $\text{C}_2\text{H}_6$ , and he had no hesitation in advancing the opinion that the specific illuminating power of acetylene,  $\text{C}_2\text{H}_2$ , would be found on determination to be much greater than that of ethylene,  $\text{C}_2\text{H}_4$ , because it was a less saturated substance. For these and analogous reasons he considered that the Dinsmore process, if they could only heat up to the necessary point and supply the duct with gases of these various characters, possessed all the elements of success. The difficulty was to regulate the temperature so as to resolve these saturated or analogous bodies into non-saturated bodies known to be luminous. As Mr. Watson Smith had pointed out at Manchester, there were several ways of representing the matter. He was still convinced, however, that the results of the process were, as he had stated in his original report, due to the breaking up of the hydrocarbons. He did not like to go further than that at the time. There were contracts at the back of his observations; and gentlemen engaged in trade would know what that meant. Therefore having regard to the tar, he had confined himself to stating that there was less benzene and the light naphthas, less light oils, more of the heavy oils up to anthracene, and more pitch than in ordinary tar, quantities by volume being given. Probably by mere accident the sample of Dinsmore tar which he had examined was more than usually viscous, it being difficult to get the water from the tar by allowing it to stand. With reference to the low specific gravity of the Dinsmore gas, he thought that his hearers, as chemists, would concede that if one could make acetylene or any similar hydrocarbon from marsh gas, thereby giving it a higher illuminating power, that was a possible explanation of the effect of the Dinsmore process. The carbon and hydrogen densities of the heavy hydrocarbons were very suggestive, and pointed clearly to the conclusion that they were bodies of the olefine rather than of the paraffin type. Mr. Watson Smith had referred to the absence of carbonic acid gas. There was some misunderstanding, as this body was always present in the Dinsmore gas. Column I. of the table gave the specific gravity of a specimen of Dinsmore gas after passing through a lime purifier. The same column gave the amount of  $\text{CO}_2$  and  $\text{H}_2\text{S}$  before the action of the lime, and the following figures of the same column gave the composition of the sample after the complete removal of  $\text{H}_2\text{S}$  and  $\text{CO}_2$ . The figures of the second column gave the composition of another specimen of Dinsmore gas after its passage through a lime purifier, while the third column gave the composition of a specimen of town gas (a mixture of Dinsmore and ordinary gas) after its passage through an oxide of iron purifier only. It would be seen that the crude gas contained 2.75 volumes per cent. of  $\text{H}_2\text{S}$  and  $\text{CO}_2$ . Some people who had argued this question had inquired: "Where are the sperm candles you claim to get from these few gallons of tar?" But the

question could not be so discussed, the expression "illuminating power equal to so many candles" being merely a convenient form of representing lighting values. The carbonic oxide was by no means exceptional. Its correct determination was troublesome. His friend Professor Thomson of King's had privately expressed to him his own experience of such difficulty. It was removed by means of euprous chloride. A mixture of gases containing carbonic oxide would even after three successive treatments contain a trace of carbonic oxide sufficient to vitiate the determination of the free hydrogen when based on the amount of oxygen needed.

Mr. F. SCUDDER said that he would like to be informed as to the illuminating power of the town gas as compared with the Dinsmore gas.

Mr. W. FOSTER replied that he would have given the figures, but feared to be wearisome. He would now give them from his report.

Town gas after purification with oxide of iron	18.6

He might add that he strongly believed in the process. One of its chief advantages would be that it would enable the cheaper classes of coal to play a very different part from what they did a few years ago. There was no merit in making 22-candle gas. At Widnes the Corporation was under contract to supply gas of much lower illuminating power. But the Dinsmore process enabled Mr. Carr to use a coal which he could not possibly employ in the ordinary method of distillation. He certainly robbed his tar to the extent of about 33 per cent. in order to attain this result; but if he could use a coal not usually considered as a gas coal, and obtainable at a lower price, and still make his gas as good or better, that was a very important point. Cannel coal was already becoming scarce in this country, and the freight from America was so great as to prohibit the use of American cannel in this country. Everything therefore tended to force the gas engineer to fall back on inferior coal. But, as the Chairman had said, it would always be a question of gas or tar; and that question must of course be settled by the relative market values of products.

Mr. F. SCUDDER remarked that the increase of illuminating power in the Dinsmore gas was about 17 per cent. But it was to be noted that the ordinary town gas contained 2 per cent. of carbonic acid. If that carbonic acid were taken out the illuminating power of the gas would be increased by 10 per cent. There was also another very ugly figure in the analysis of the town gas, namely, free nitrogen 1.1, whereas the Dinsmore gas showed only 0.5, which entailed little loss of illuminating power. If these two faults were corrected (and it was to be remarked that the quantity of nitrogen was extraordinary) it would be found that the illuminating power of the two gases was practically the same. It would be interesting to know what kind of hydrocarbons the 6.6 was composed of; for instance, what was the proportion of benzene vapour? He would also be glad to know how long the gas was kept before it was tested. He could quite understand gas being prepared with tar at 230° F., in which case the illuminating power would be increased; but if the gas were kept for two days the illuminating power would go back, and the hydrocarbons would condense from the gas. No experiments had been brought forward to show the permanent character of the Dinsmore gas.

Dr. C. R. ALDER WRIGHT had not had the advantage of hearing the earlier part of the paper, and was therefore running the risk of putting questions which need not have been put if he had been present from the first. He would like to know precisely what the terms "carbon density" and "hydrogen density" referred to in the table displayed

giving the relative compositions of "Dinsmore gas" and "town gas." He thought he understood, but was not quite sure. He assumed that they referred to the average state of condensation in the hydrocarbons other than marsh gas; so that, taking the first specimen, 5.3 per cent. of hydrocarbons containing carbon at the density of a little less than .3 would contain about the same amount of carbon as would be present in about 15 per cent. of CO. In other words, he understood "carbon density" to mean the average number of carbon atoms per molecule of the hydrocarbons. If that were the correct interpretation, he could not see that the figures were much in excess of those ordinarily obtained with gas coal, or gas coal with cannel. He remembered years ago making some analyses of Rochdale gas by Bunsen's method, where the amount of hydrocarbons absorbable by fuming sulphuric acid ranged between five and seven, and represented an amount of carbon condensation equivalent to from a little under to rather over three atoms of carbon in the molecule. In other words, the carbon was in a more condensed state on the average than in ethylene approximately in the same state of condensation as in propylene. Analogous results were obtained more than 30 years ago by Bunsen with Manchester gas, and described in his "Gasometry." He would like to know how the figures were obtained for the percentages of hydrocarbons, whether by fuming acid or bromine; and if there were any certainty that other hydrocarbons of the paraffin class (*e.g.*, dimethyl or ethane) were wholly absent; for if not, the ordinary method of determining hydrogen marsh gas and carbonic oxide would be wholly fallacious. Assuming that the town gas was made from the same coal as the Dinsmore gas—and even apart from that assumption—it was difficult to understand how one could materially diminish the amount of marsh gas and correspondingly increase the amount of hydrogen, and yet keep the density practically constant. It seemed at first sight as if the figures quoted were incompatible in that respect. Then as regarded the hydrogen density in the hydrocarbons, he would like to know how the figures had been determined. As they stood they indicated that the hydrocarbons belonged to the ethylene series; so that benzene and less hydrogenised hydrocarbons would seem to be almost wholly absent. He did not know if that was the result of the breaking up taking place in the duct; but if it were, it was then not difficult to understand how the total volume of gas produced was increased in the process. He did not gather that the actual yield of tar constituents had been calculated out per ton of coal. The percentages of the various constituents contained therein were intelligible enough as they stood; but if one reckoned them per ton of coal, it might be that in one case one would get only one-third the proportion obtained in another case, and so on; it was obvious that the percentage compositions alone did not tell the whole story. He was asking these questions simply for his own satisfaction, and trusted that they were not out of place.

THE CHAIRMAN felt that the course of the discussion had placed him in a condition of some difficulty, inasmuch as although Mr. Watson Smith was the author of the paper before the meeting, the criticisms and questions which it had called forth were addressed chiefly to Mr. Foster. Under the circumstances, therefore, he would call upon that gentleman to reply.

Mr. W. FOSTER replied that in the first place he would like to call attention to the town gas given in the right hand column. If the carbonic anhydride were removed the density would work out to .382. It was obviously paradoxical, however, to have a gas of that high value and very low specific gravity. Mr. Scudder had inquired about the heavy hydrocarbons, and the answer to him would apply also to Dr. Wright. The volume of those hydrocarbons was determined by absorption with Nordhausen sulphuric acid. The amount of carbonic anhydride produced by these bodies, and the amount of oxygen needed for their combustion, furnished the experimental data. The figures for the carbon and hydrogen densities gave the *average molecular* composition of the substances present. There was no attempt made to differentiate the substances classed under the head "heavy hydrocarbons," that being quite impossible

at the time. But the specific gravity of the sample was taken at the time by means of a special globe kindly made for him by Mr. Lennox, of the Royal Institution, to whom he was much indebted in many ways. The gas was always kept for a day in a holder exposed to the air laterally in the month of November. No attempt whatever had been made to nurse the gas. He had gone down to Widnes under somewhat exceptional circumstances, but though aware of some hostility to the process he had tried to keep a perfectly judicial mind, and had recorded everything as he had found it. If there had been any attempt at padding, the amount of carbonic anhydride in the town gas remarked upon by Mr. Seadder would have been different. He scarcely ever found a sample of coal-gas containing less than 1 per cent. of nitrogen. One did not like to call in question the work of a confrere; but a distinguished chemist, who was probably a member of that Society, had quite recently recorded as much as 10 per cent. He thought he knew how he had found that figure, and why. Certainly 1 per cent. could not be considered high, when it was remembered that coal-gas was passed through purifiers to which the air had access during the transfer of material for purification. Air was always introduced in small quantity during the charging of the retorts and through the action of the gas exhauster.

MR. WATSON SMITH, in answer to Dr. Alder Wright, desired to say that the yield of tar per ton of coal carbonised in the ordinary retorts is about 11 galls. The same coal carbonised by the Dinsmore process would yield about 7 galls. per ton. It must, however, be borne in mind that the coal from which these quantities of tar are obtained is of low class quantity, a good Arley mine coal yielding from 12 to 13 galls. of tar per ton. He also wished to say one word with regard to the absence of carbon dioxide in Dinsmore gas, which was the only point upon which he had seemed to be at variance with Mr. Foster. He had founded his views on that head, and it now appeared erroneously, at the Manchester meeting, from statements he had heard there and had taken to be originated by Mr. Foster. Now that Mr. Foster assured him that the result he had mentioned was not really in accordance with his figures, he, of course, withdrew the application of his theory accounting for it. At the same time he believed that the reaction would be in that direction, for if carbon dioxide passed into a duct containing red hot carbon it must be reduced to some extent.

MR. F. SCUDDER remarked that in that case the carbonic oxide would increase; whereas, according to the analyses, it was less in the Dinsmore gas than in the town gas.

MR. W. FOSTER replied that there was no evidence before them yet as to what the town gas was before the Dinsmore gas was mixed with it, and he thought that the Dinsmore Company were a little at fault in that matter. They would like to know exactly what an ordinary coal would do by the ordinary method, and then ascertain how the same coal behaved under the Dinsmore method. He was informed that Mr. Duxbury, of Darwen, had instituted experiments of the character he had suggested.

### BÖTTINGER'S NEW REACTION FOR TANNIC AND GALLIC ACIDS.

BY WATSON SMITH.

MR. WATSON SMITH illustrated this reaction by heating separately small quantities of the above acids with double their weight of phenylhydrazine for a few minutes to a temperature slightly over 100° C., adding a little water, and boiling for a few seconds, and then allowing a drop or two from either vessel to fall into large beakers containing water which had been made alkaline with caustic soda.

In the case of the tannin compound, a beautiful blue colouration was developed, gradually subsiding into yellow, whilst in that of the gallic acid hydrazide, an orange or golden yellow colouration was produced.

The details of this method and its *rationale* will be found on page 555.

### DISCUSSION.

THE CHAIRMAN said that the chemistry of these allied but totally different acids was always a matter of interest, but in the present case the meeting had to consider an entirely novel reaction. He hoped that if there were any members present who had studied these bodies and their reactions, they would give the meeting the benefit of their views as to the practical applicability of such a process as Mr. Watson Smith had described.

MR. CROWDER inquired whether the reaction was intended as a test for quantitative purposes, or whether it was simply a qualitative test?

MR. WATSON SMITH replied that at present the reaction was simply qualitative, but what it might come to ultimately he did not know.

MR. CROWDER asked if it was to be regarded as a qualitative reaction which might be used for a quantitative process?

MR. WATSON SMITH replied in the affirmative.

MR. C. F. CROSS inquired whether the reaction had been studied so far as to determine the constitution of the bodies?

MR. WATSON SMITH replied that it had been studied by Herr Böttinger, and that a detailed account of the research, so far as it had gone, was given in the article from which he had quoted. There appeared to be a certain amount of mystery in connexion with the substances which had as yet been only partially isolated.

### SOME CONSIDERATIONS ON THE CHEMISTRY OF HYPOCHLORITE BLEACHING.

BY C. F. CROSS AND E. J. BEVAN.

WITH the assistance of our friend and pupil, Mr. F. E. Nelson, we are investigating the reactions which take place in the processes of bleaching vegetable fibres, confining ourselves for the present to those in which the chloroxygen compounds are used.

In the subjoined brief account of our results we shall endeavour to elucidate the following points:—

(a.) Bleaching by means of the hypochlorites is attended with chlorination of the fibre constituents, more or less, according to the nature of the basic constituent of the bleaching solution and the condition of the fibre substance.

(b.) The chlorination is conspicuously less in the case of magnesium hypochlorite—prepared by double decomposition from bleaching powder—and still less in the case of solutions prepared by electrolysis of  $MgCl_2$  Aq.

(c.) The evidences of chlorination are: (1), a portion of the chlorine of the bleaching solution does not revert to the condition of hydracid, *i.e.*, chloride, and in consequence, a portion of the base with which it was combined as hypochlorite, is otherwise combined than as chloride in the exhausted mixture (solution and fibre substance); (2), "organic" chlorides are present in the washed pulp.

(d.) The factor of chlorination differentiates bleaching by means of hypochlorites from those processes in which the only possible factors are oxidation and hydrolysis, *e.g.*, bleaching with permanganates and hydrogen peroxide.

(e.) The cause of chlorination lies in the presence of ketonic oxygen in the fibre constituents (non-cellulose).

Also the following points of practical rather than theoretical import :—

(f.) The simple and accurate method of determining the "free base" in hypochlorite solutions, by direct titration after destroying the hypochlorite by means of hydrogen peroxide.

(g.) As a result of such determinations, that the proportion of free base to hypochlorite, in solutions made from bleaching powder at various concentrations, varies inversely with the concentration.

(h.) That bleaching, to be efficient, economical, and safe requires a careful regulation of the several factors; these are, translated from their more theoretical expression under (d), nature and proportion of the basic constituent, both free and combined; the temperature of the solution; and the nature (composition) of the negative or oxidising constituents.

(i.) The presence of organic chlorides in bleached esparto and straw pulps is a probable result of the bleaching process, requiring the careful attention of the paper-maker.

Before proceeding to our experimental matter, we may, perhaps, be allowed to offer a few considerations in *a priori* elucidation of these several heads of the subject.

(a.), (b.), (c.). If the chlorine of a hypochlorite solution act only indirectly, if, *i.e.*,  $\text{Cl}_2\text{O}$  act, as regards bleaching, as  $\text{O}_2$ , it will revert in the process entirely to the hydracid, that is, to  $\text{CaCl}_2$ . Chlorine or base otherwise combined, at the conclusion of the bleaching, than as calcium chloride, is an indication that the process is complicated by other reactions, *e.g.*, chlorination of the fibre constituents. Deficiency of "total chlorine," would indicate loss, either as volatile  $\text{ClO}$ -compounds, or an organic chloride of low molecular weight, *e.g.*, chloroform. By means of the inorganic constants alone, therefore, the problem of their mode of action admits of solution in general terms, and the experimental evidence which we have to offer in this paper is chiefly concerned with these.

Bleaching consists for the most part in the isolation of a pure cellulose from a compound cellulose. Such is the cotton bleach (cloth and yarn) and the linen "bottom bleach" (almost exclusively cloth), as well as the preparation of pulps for white papers. In these cases the bleaching process proper is preceded by a severe treatment of the raw material—generally a digestion with alkaline lye at high temperatures—which removes the greater proportion of the non-cellulose constituents, leaving the bleaching solution little more than residues of these to deal with. In contradistinction to these, there are the kinds of bleaching which are well called "whitewash" bleaches, in which the purpose is to whiten, as far as possible, a compound cellulose itself, by removing colouring matters, either adventitious (*e.g.*, chlorophyll and proteid residues) or products of change of the fibre substance. In such bleaches the purpose is to resolve the compound cellulose as little as possible, for resolution means loss of weight and, in cases where the fibre is made up of units of microscopic length—as in jute, with an ultimate fibre of 2—3 mm.—serious loss of strength. In this category we include, in addition to jute bleaching, whether for textiles or coloured papers, the various treatments of linen yarn known as "creaming," "half," and "three-quarters" bleach, and also some of the paper-makers' bleaches for low-grade papers. In all these cases the consumption of the bleaching-agent is relatively high. This, of course, immediately follows from the more-oxidisable character of the non-cellulose constituents of fibres. The distinction in this respect between cellulose and non-cellulose may be more definitely expressed in terms of their actual constitution, so far as ascertained. In the latter we have ketonic, aldehydic, and hydroxylic oxygen, either or all, with the "reactivity" characteristic of the presence of the CO, COH, and OH groups (Watts' Diet., New Ed., Art. Cellulose; also C. S. J., 1889, 199, and 1890, 1), whereas in cellulose we find none of the reactivity characteristic of an aldehyde or ketone; and even the hydroxyls, if present as such, are abnormally inactive. The directions of attack presented by such compounds to the alkaline hypochlorites are, in the case of the non-cellulose constituents, obviously,

oxidation and hydrolysis, and in lesser degree, also chlorination, the cellulose, on the other hand, remaining inert so long as a certain limit of intensity of oxy-hydrolytic action is not exceeded.

As subjects of experiment, we have confined ourselves for the most part to esparto and wood pulps prepared by the alkali process, as practised in a "news" mill; that is, pulps boiled so as to retain a maximum of non-cellulose constituents consistent with the degree of whiteness required for cheap printing papers. As bleaching agents, we have investigated the hypochlorites of calcium, sodium, and magnesium—the two latter prepared by double decomposition from the former—and, in addition, the solutions prepared by electrolysis from magnesium chloride.

(f.) A satisfactory method of estimating the oxides in presence of the hypochlorites (of the alkali and alkaline earths) has not, so far as we are aware, been proposed. The usual method of destroying the hypochlorite by ammonia, boiling off the excess and estimating the residual oxide, is open to an error resulting from the interaction of ammonia and hypochlorous acid, with formation of a volatile compound containing the elements of the latter combined with ammonia (Cross and Bevan, Proc. C. S. 1890, 22). That the results obtained are in excess of the actual amount of free lime present we have found by comparison of this method with those about to be described. The cause is obviously due to the loss of chlorine and the setting free of the equivalent of base.

The destruction of the hypochlorite by means of a solution of arsenious acid containing a known quantity of alkali, and subsequent titration of the total alkalinity, is unsatisfactory from the want of sharpness of the colour changes with the ordinary indicators. Sulphite of soda, oxidised by the hypochlorites to the neutral sulphate, appears to satisfy the required conditions; and the results obtained by subsequently titrating the free base in presence of phenolphthalein, are concordant and in fair agreement with those obtained by a method which we describe last, but which we should put first in order of simplicity and accuracy. This method consists in destroying the hypochlorite with hydrogen peroxide, which may obviously be used in excess without affecting the subsequent titration—and estimating the residual free base with acid; allowance being, of course, made in calculating the result for the acidity of the peroxide solution.

We subjoin the results of estimating the free lime in filtered solutions of calcium hypochlorite, which, besides illustrating the method, bring out a fact of some practical importance, *viz.*, that in dissolving bleaching powder the quantity of free lime taken up, calculated upon the chlorine strength, varies inversely with the concentration, *i.e.*, is approximately constant for the unit volume of solution.

Hydrogen peroxide: "10 vol." solution. Acidity, 1 cc. =  $0.34 \frac{\text{N}}{10}$  acid.

Hypochlorite solution: 10 cc. used in each determination.

—	Cc. $\text{H}_2\text{O}_2$	Free CaO per 10 cc.	Ratio. Free CaO to CaO as $\text{Ca}(\text{OCl}_2)$ .
10 grms. bleaching powder to 100 cc. ....	8.50	0.0070	1:20
7.5 grms. bleaching powder to 100 cc. ....	6.30	0.0073	1:14
5.0 grms. bleaching powder to 100 cc. ....	4.30	0.0087	1:8
2.5 grms. bleaching powder to 100 cc. ....	2.15	0.0078	1:4.5

The proportion of free to total combined CaO in the bleaching power itself has been found by O'Shea\* (C. S. J., 1883, 417) to be about 1:2.4; one-half of the combined CaO, however, reverts on solution to  $\text{CaCl}_2$ , the other half

\* These determinations were made by means of the ammonia method.

remaining combined with the chloroxygen group. The ratio of free to combined CaO expressed uniformly with those of the last column of the above table is 1:1.2; i.e., in a mixture of bleaching powder and water there is nearly as much CaO free, as in combination as hypochlorite.

It is obvious, therefore, that a sodium hypochlorite solution prepared by double decomposition from an unfiltered solution of bleaching powder will contain free soda in this proportion: prepared, on the other hand, from a clear solution, the proportions will be those of the above table.

Magnesium hypochlorite solutions similarly prepared show, on the other hand, a minimum basicity, owing to the relative insolubility of the oxide. These points are worthy of note in connexion with the practical work of bleaching.

We now pass to the experimental investigation of the bleaching process itself.

The points which we aimed at determining in the first place was, as already explained, (1), the proportion of base combined otherwise than as chloride in the exhausted mixture (solution and pulp); and (2), the distribution of the chlorine. As regards (1), the data required are relative rather than absolute, and we have taken as the measure of this factor the volume of standard acid required to neutralise in presence of methyl orange. The numbers obtained afford certainly minimum values for base not reverting to chloride, and a sufficiently exact comparison of the various solutions for the purposes of this investigation.

In our first experiments the conditions were such as obtain in the ordinary process of bleaching. The well-washed pulps (esparto and wood) were digested at ordinary temperatures

with the bleach liquor diluted to 20—30 times the weight of the pulp. The "available chlorine" taken varied from 2.2 to 6.6 per cent. of its weight. In calculating the results, due allowance was made for the free base in the bleach solution, and for the basicity of the water employed. The following were the general conclusions arrived at:—

The proportion of base not reverting is highest, and approximately the same, for soda and lime, lowest for magnesia, viz., from 20—to 30 per cent. for the two former, 10—15 per cent. for the latter. The proportion is higher in the early stages of the bleaching. As regards the distribution of the base between pulp and solution, an average of the numbers showed that in the case of lime,  $\frac{2}{3}$  was present in the pulp, in the case of soda only  $\frac{1}{3}$ , in the case of magnesia the distribution was approximately equal.

To establish an exact comparison between the several hypochlorites, in regard to this particular point, experiments were made in series and simultaneously, under uniform conditions, the base alone being varied.

The pulps were prepared by digesting in dilute acid and thoroughly washing off with distilled water; the bleaching solutions were also made up with distilled water. To give clearer expression to the results the numbers—for base—are given in cc. of normal acid required to neutralise. The particulars of the experiments are as follows:—

In each case we employed 20 grms. pulp and 500 cc. solution containing 1.010 grms. "available Cl," combined with base equivalent to 14.3 cc. normal acid. Experiments in each case simultaneous. Time, 18 hours.

Bleaching Agent.	Base as MOCI= cc. normal Acid.	Base after Exhaustion = cc. normal Acid.		Proportion of Base not reverting to Chloride.
		Pulp.	Solution.	
<b>A. Wood pulp:</b>				
Calcium hypochlorite .....	14.3	1.25	2.5	Per Cent. 26.0
Sodium hypochlorite .....	14.3	1.0	2.0	21.0
Magnesium hypochlorite.....	14.3	0.9	1.0	13.0
<b>B. Esparto pulp:</b>				
Calcium hypochlorite .....	14.3	2.2	2.0	29.5
Sodium hypochlorite.....	14.3	0.75	3.25	27.8
Magnesium hypochlorite.....	14.3	0.65	1.75	16.5

These results differentiate magnesia from lime and soda, the two latter appearing closely similar in their actions.

It was important to examine, in the next place, the mode of action of the bleaching solutions prepared by electrolysis magnesium chloride in dilute solution. We prepared two such solutions, uniform as regards chlorine strength with the above. In one we employed the pure salt alone; in the other magnesia was added in excess at the commencement of the electrolysis. The former solution, treated with the equivalent of sodium sulphite, was brought to exact neutrality; the latter was found to contain 12.5 per cent. of magnesia in excess of the equivalent of the chlorine set free by the electrolysis. Bleaching experiments were performed, using these solutions under conditions exactly uniform with the above. In the case of the first solution the mixture after exhaustion was neutral; in the second, the residual base was exactly that contained in the original solution in excess of the equivalent. *In these solutions, therefore, there appears to have been a complete reversion to chloride.*

The proof that the bleaching process is or is not attended with chlorination of the pulp constituents, is so far only inferential. Direct experimental evidence of chlorination in bleaching with calcium hypochlorite is afforded by the following observations:—Esparto pulp was freed from chlorine by digestion with dilute nitric acid (containing some sulphurous acid) and thoroughly washing. 6.4 grms. of this pulp was bleached under the usual conditions with 10 cc. of a solution of bleaching powder (7.2 per cent.), the total chlorine in which was estimated in a second quantity. After exhaustion the pulp was washed free from soluble

chloride, the original solution and washings being treated with silver nitrate. The washed pulp was "fused" with pure sodium hydrate, and the chlorine determined in the fused residue. The numbers obtained were:—

Cl in exhausted solution .....	0.2414
Cl in pulp .....	0.0255
Total Cl.....	0.2669
Total Cl in original bleaching solution.....	0.2750
*Difference .....	0.0081

The presence of an "organic" chloride in the pulp thus indicated was confirmed by taking a second portion, and after bleaching and washing till free from soluble chloride, drying and exhausting with alcohol. The alcoholic solution gave a copious precipitate of chloride with silver nitrate. On distilling off the alcohol from the remainder an oily residue was left, which was found to be partially soluble in sodium sulphite solution, with formation of sodium chloride.

Some years ago we called attention to the chlorination of the jute fibre in the bleaching of textiles with calcium hypochlorite, and the consequences attending the subsequent decomposition of the chloride in the fabric (Bull. Mulhouse, 1882). From what is now known of the constitution of the fibre substance there can be little doubt that it is the

\* This difference is a loss of Cl, either escaping during the bleaching process or in that of "fusing" the pulp with alkali, or it may be due to Cl in the exhausted solution not reacting with AgNO<sub>3</sub>. In any case the proportion is small.

ketonic oxygen which opens up a path to the chlorine, and the same cause would appear to be at work in the case of the esparto; for, on removing portions of the fibre, washing with water and sulphurous acid, and treating with magenta-sulphurous acid the characteristic reaction is obtained upon the fibre. The presence of a chloride in bleached pulps, not removable by washing, is a point of considerable practical importance. Such a chloride may be presumed to have acid properties, and its formation to account in part for the retention of the basic constituents of the bleaching solutions. The presence of the latter doubtless safeguards the fibre from being attacked by the hydrochloric acid, which would result from the hydrolysis of the chloride in the after processes of working up the pulp, but no doubt also tends to increase the discolouration ("going back") of the pulp resulting from the same cause. We would further remark that the presence of chlorine in a paper is also seen to be not necessarily an evidence of imperfect washing.

We now have to consider briefly the somewhat vexed question of bleaching efficiency. So far we have not spoken of the quality of the bleach obtained with the solutions which we have investigated. We do not, indeed, propose to go into a detailed account of the numberless experiments which we have made on this subject, in comparing the results obtained with the various systems used or proposed to be used. These more recent investigations have shown us that wide variations in efficiency are to be expected even when the actual bleaching agent is a constant quantity, and that no measure of the efficiency of a process will be complete which does not take into account the influence of the several factors. We cite one or two considerations in illustration. Thus *hydrolysis* will vary with the several bases, their proportion to pulp and solution, with the temperature, and evidently also with the condition of the pulp. *Oxidation*. The mode of action of the active constituent of a bleaching solution, we may assume, will not be seriously affected by variations of temperature within the ordinary range, nor directly influenced by the base with which it is combined. But the indirect influence of both, through the influence on the hydrolysis, may be considerable. We may cite experiments in illustration of these points.

(a.) *Temperature*.—Two identical solutions of bleaching powder were employed upon esparto pulp, the one being kept at 35° C. the other at 0°—4° C. The former was washed off when the solution was exhausted (2 hours), the latter allowed to remain until brought up to an equal colour (5½ hours). The residual chlorine in the latter was determined and found to amount to 20 per cent. of the original; also the proportion of base not reverting to chloride was found to be 40 per cent. less than in the experiment at the higher temperature.

(b.) *Quantity of base*.—Five solutions of sodium hypochlorite was prepared, in one the proportion  $\text{Na}_2\text{O} : \text{Cl}_2\text{O}$  was approximately normal, to the four remaining,  $\text{Na}_2\text{O}$  was added to increase the molecular proportion by 1, 2, 3, 4, units. At the conclusion of the experiment the solutions were found equally exhausted and the gradations of bleach were exactly in inverse order with the increments of base.

We should interpret these results as follows:—

(a.) At the lower temperature hydrolysis and tendency to chlorination are lessened: the same result as regards colour being obtained with a consumption of 20 per cent. less of the bleaching agent, the economy is due to limiting its work to that of simple oxidation, and the hydrolysis being a minimum, the oxidation is rather confined to the constituents upon the fibre, and not used up inefficiently in further oxidation of dissolved substances.

(b.) By the addition of alkali the hydrolytic tendencies are increased, and the sphere of oxidation is consequently extended, probably to the cellulose itself. It is well known in fact that with very alkaline oxidations the cellulose fibres are weakened, and fabrics are thus "tendered." The probable results therefore would be ineffectual oxidation—ineffectual, i.e., from being extended beyond the range of the colouring constituents, and even probably by promoting tendencies of the opposite kind to that desired, i.e., tendencies to fix the products of oxidation upon the cellulose.\*

\* In linen goods "dipped" before the "bottom" is "out" the difficulty of bleaching is much increased; the bottom, i.e., the non-cellulose residues, are fixed on the cellulose.

Lastly, the factor of *chlorination* in relation to bleaching efficiency is an element, *sui generis*, of the process of bleaching with the hypochlorites, upon the advantages or disadvantages of which we would not as yet pronounce any final opinion. Of course we may find that it plays a more important and necessary part than would appear from a study of the final products of the process. Further investigation of the hypochlorites, compared amongst themselves and with bleaching compounds into the composition of which chlorine does not enter, will lead to a definite solution of the problem, and this we have no desire to anticipate.

The presence of residual organic chlorides in bleached pulps is a disadvantage which we need not emphasise, and to the danger of which practical men will be alive. This matter certainly requires attention at their hands.

Generally we would remark that the familiar operations of the bleacher, to be recognised as definite chemical processes, require extended investigation and establishment upon a basis of exact knowledge, from which they will come to be presided over by instructed common sense and not by the much invoked genius of "fog."

## MOISTURE IN PAPER PULP.

BY MARTIN L. GRIFFIN, OF HOLYOKE, MASS., U.S.A.

MR. G. H. GEMMELL'S paper on moisture in paper pulp, read before this Society and published in the February number of its Journal, leads me to give the results of my experience as to the proper amount of atmospheric moisture allowable in paper pulp, and the methods of sampling and making the correction for atmospheric moisture. As the chemist to a soda fibre mill producing daily 30 tons of paper, this question was brought to my attention very early. Uniformity in results by different observers is not to be expected, because there are so many different conditions which enter into the question.

The term "atmospherically dry" as applied to paper pulp in its usual form is not satisfactory to me for this reason: it is not dried in the atmosphere, but usually passed over a machine to dry it, and while it is easy to dry a sheet of pulp in the air so that it does not feel moist, it is equally true that pulp may be atmospherically wet from such exposure. There is every gradation of moisture in this New England climate from the minute amount in January, when the thermometer is 25° below zero, to that during the rains of April and the thunder showers of July and August. I have a galvanised iron closet so arranged that neither snow nor rain can enter, yet freely accessible to air, for the exposure of samples; nevertheless, fog and mist, which we frequently have during certain seasons of the year, make samples so exposed feel wet to the touch. No one would call such fibre dry.

A certain amount of moisture should be allowed before a complaint is instituted, but this does not signify that the average limit should be aimed at any more than, when the law fixes the standard of purity of new milk at 13 per cent. milk solids, that all milk producers should reduce the quality to this standard. Every paper or pulp manufacturer would object to receiving lime air-dried or hide cuttings for sizing air-dry. Such cuttings easily absorb 20 to 25 per cent. moisture without feeling moist.

Not only do fibres from different sources acquire different proportions of moisture, but the same kinds differ in this respect according to the formation of the sheet and the pressure upon it. Some mills make a very light and soft fibre, while others make a stiff and harsh fibre from precisely the same kind of wood, and each takes up a different amount of moisture accordingly.

During the year 1884 I exposed daily about 10 samples of pulp dried at 212° in a room having windows open and with no fire, with the result that they gained by atmospheric moisture 6.38 per cent.

## MOISTURE TESTS.

November .....	+ 2'23	9'21
December.....	+ 1'04	9'21
Average.....	+11'76	7'40

Above I give the results of the average for each month in the year 1886 with the corresponding mean departure from the average precipitation for New England. There were from three to five samples previously dried at 212° exposed daily for a week in a well-aired brick storehouse, with cellar and good floor. These samples weighed 50 grms. each, were poplar fibre made by the alkaline process, and the sheets were comparatively thin, as pulp is usually made. It will be observed that the year 1886 was nearly normal in New England as regards precipitation, and substantially confirms my standard adopted, namely, 6'38 per cent.

I have also given the results for the year 1888, which were the same in method except that the samples were exposed in my air-closet referred to above, and the observations included weighing the same 20 samples daily without intermediate drying, allowing them to fluctuate according to the conditions of the atmosphere, and renewing them about once in three months.

It has been my experience that atmospheric changes will make as great a difference as 5 per cent. at times. 1888 was a wet year and the precipitation was 26'26 per cent. above the mean average during the whole year. The average increase by moisture for the year was 7'40 per cent.

As I sample most of the pulp in the consumer's mills, I remove a sample sheet about one-third the way in from the exterior usually, and in lots of 200 bales or rolls and

under 1 sample 10 per cent., above this number I take 20 samples.

To make the mathematical correction for atmospheric moisture, two methods may be employed. First, we may say that the standard is, in every 100 lb. commercial fibre, 94 lb. absolute fibre and 6 water, therefore, if we purchase fibre which dries so that every 100 lb. as invoiced weighs only 85 lb. containing 15 lb. water, to find what these 85 lb. would become atmospherically dry, the inquiry is stated thus: If 94 lb. become 100 on exposure to the air, what will 85 lb. become? The result is 90'42 lb. This method has nothing to do with percentage, and every reference to percentage should be avoided or mistakes will occur. The other method is purely by percentage. Let us consider the same example. Our standard by the first method was in 100 lb., 94 should be fibre and 6 water. If, therefore, 94 lb. fibre has gained 6 lb. water on exposure it has acquired 6'38 per cent. moisture and our percentage standard is 6'38. The problem is solved by finding 106'38 per cent. of 85, which gives 90'42 lb. as above.

My results have been generally accepted by domestic manufacturers. Foreign manufacturers have not as a rule come down to this standard, but no longer claim 12 per cent. in our markets here, and of late many invoices are dry according to the standard named in this paper.

For 1886 the excess percentage precipitation was 2'21 per cent.

The excess percentage of the average increase by moisture (7'04) over my standard (6'37) is 10'51 per cent.

For 1888 the excess percentage precipitation was 26'26 per cent.

The excess percentage of the samples over the standard was 16'17 per cent.

## DISCUSSION.

The CHAIRMAN said that members of the Society were always glad to have results of this sort which had been obtained in other climates and under circumstances different from those which generally ruled in England. If the phraseology of the paper were translated into the more ordinary language of this country, that would materially assist members in appreciating its full value. In a climate in which the difference between a wet and a dry day accounted for as much as 5 to 10 per cent. in the estimation of moisture in certain goods, the "precipitation of water which we call rain" became a matter of considerable importance.

Dr. C. R. ALDER WRIGHT did not see how a correction was to be applied to a bale of material only the outside of which was exposed to the air. If a truss of hay, for example, were exposed to a damp atmosphere for a few days, the outside of it might be thoroughly water-logged, while the inside might be in good condition. It would be better, he thought, though it might not be the usual practice of that trade, to adopt a system by which an average sample was estimated, and a *pro rata* deduction made for the moisture present, as was done in the case of the sale of pyrites and such like goods.

Hon. Treasurer: W. P. Thompson.

Hon. Local Secretary:

Dr. C. A. Kohn, University College, Liverpool.

The names in Italics are those of members of Committee who retire at the end of the current Session.

The following have been selected to fill the vacancies, and will take office in July next:—Chairman: A. Norman Tate; Vice-Chairman: F. Hurter; Secretary: Chas. A. Kohn; Treasurer: W. P. Thompson; Committee: C. L. Higgins, A. H. Knight, E. K. Muspratt, and A. Watt.

SESSION 1889-90.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

Meeting held on Wednesday, 7th May, 1890.

DR. J. CAMPBELL BROWN IN THE CHAIR.

### PHOTO-CHEMICAL INVESTIGATIONS AND A NEW METHOD OF DETERMINATION OF THE SENSITIVENESS OF PHOTOGRAPHIC PLATES.

BY FERDINAND HURTER, PH.D., AND V. C. DRIFFIELD.

#### I.—WHAT IS A PERFECT NEGATIVE? DENSITY, OPACITY, TRANSPARENCY.

THE production of a perfect picture by means of photography is an art; the production of a technically perfect negative is a science.

A perfect negative demands, in the first place, a perfect plate, and as the manufacture of dry sensitive plates is a large and rapidly-growing chemical industry, we need offer no apology for bringing this subject before this Society.

Our researches, which have covered a period of over 10 years, were made with a view to rendering the production of perfect negatives as far as possible a matter of certainty.

What is a perfect negative? A negative is theoretically perfect when the amount of light transmitted through its various gradations is in inverse ratio to that which the corresponding parts of the original subject sent out.

The negative is mathematically the true inverse of the original when the opacities of its gradations are proportional to the light reflected by those parts of the original which they represent.

Before we can clearly understand this definition, it will be necessary to state shortly the laws of absorption of light by opaque black substances, and to define clearly the meaning we attach to the terms opacity, transparency, and density of a negative. It is the more necessary to do this, as the whole of our investigations depend upon these laws.

For substances which do not reflect much light, such as black opaque bodies, or transparent coloured bodies, the relation between the light absorbed and the quantity of the substance present is very simple. If between the eye and a source of light we place a thin layer of dilute Indian ink, that layer absorbs light, and thereby reduces the intensity of the light transmitted. Assume that such a layer absorbs one-half of the light, then one-half of the light will be transmitted. Whatever may be the intensity of the original light, the intensity after passing this layer of ink will be one-half of what it was. The interposition of two such layers will reduce the light to  $\frac{1}{4}$  the original intensity; three such layers will reduce it to  $\frac{1}{8}$ , and so on, each layer reducing the intensity to one-half of what it receives.

Had the first layer allowed  $\frac{1}{3}$  of the light to pass through, then two such layers would reduce the intensity to  $\frac{1}{9}$ , three layers to  $\frac{1}{27}$ , &c. In general any number of layers would reduce the intensity of the light to a fraction, which is equal to the fraction the first layer allows to pass, but raised to a power, the index of which is the number of layers employed. If  $n$  equal layers were employed, and the first one reduced the intensity of the light to a fraction  $\frac{1}{m}$ , the  $n$  layers would reduce it to  $\left(\frac{1}{m}\right)^n$ .

If instead of using so many successive layers, the first layer were made to contain as much Indian ink as the  $n$  successive layers contain altogether, we should find that the one layer now reduces the intensity of light by exactly the same amount as the  $n$  layers did. The reduction of the intensity is of course due to the black particles, and depends simply upon the number of them which are interposed per unit of area. We can thus replace the number of layers by the number of particles, and the law takes this form:—The intensity  $I_x$  of light after passing  $A$  molecules of a substance is a fraction of the original intensity  $I$ , such that—

$$\frac{I_x}{I} = \left(\frac{1}{C}\right)^A$$

For purely mathematical reasons the fraction  $\frac{1}{C}$  is usually expressed as a negative power of the base of the hyperbolic logarithms  $e$ , say  $\frac{1}{C} = e^{-k}$ , and we can write—

$$\frac{I_x}{I} = e^{-kA}$$

where  $k$  is called the coefficient of absorption. This form of the law we shall frequently use again. The fraction  $\frac{I_x}{I}$  represents and measures the transparency of the substance.

The inverse of that fraction, or  $\frac{1}{\frac{I_x}{I}} = \frac{I}{I_x} = e^{kA}$  measures the opacity of the substance. It indicates what intensity of light must fall on one side of the substance in order that unit intensity may be transmitted.

In our investigations we use the letter  $T$  to denote transparency, and  $O$  to denote opacity, and the two symbols are related thus:  $O \times T = 1$ .

We must further define what we mean by density as distinct from opacity. By density we mean the number of particles of a substance spread over unit area, multiplied by the coefficient of absorption;  $kA$  is what we term density, and mark by the letter  $D$ .

For our purposes, *i.e.*, in its application to negatives, the density is directly proportional to the amount of silver deposited per unit area, and may be used as a measure of that amount.

The relations between the three terms, transparency, opacity, and density, are the following:—

$$T = e^{-D}$$

$$O = e^D$$

$$D = \log e O = -\log e T$$

The density is the logarithm of the opacity, or the negative logarithm of the transparency.

These relations hold good for some substances with regard to ordinary white light, for others only with regard to monochromatic light, and for others they do not hold good

at all. We have satisfied ourselves that they do hold good for the silver deposited as a black substance in negatives so long as the silver does not assume a metallic lustre, and reflects but a very small amount of light.

By means of these definitions we are now in a position to trace the connexion between the densities of a theoretically perfect negative and the light intensities which produced them.

Since the density is the logarithm of the opacity, and since, in a theoretically perfect negative, the opacities are directly proportional to the intensities of the light which produced them, it follows that each density must be proportional to the logarithm of the light intensity which produced it. (More correctly, the density is a linear function of the logarithm of the intensity of light and time of exposure.)

The result is this:—In a theoretically perfect negative, the amounts of silver deposited in the various parts are proportional to the logarithms of the intensities of light proceeding from the corresponding parts of the object.

The question arises, can such a negative be produced in practice?

In order to answer this question, we had first to find a simple method of measuring the density of the silver deposited in negatives. We had then to study the influence of the developers upon the density of the deposits, and we were then in a position to investigate the action of the light itself.

## II.—INSTRUMENT FOR MEASURING DENSITIES.

We proceed to describe the instrument for measuring the density of the deposit. It is based on the relation existing between density and opacity. We measure the opacity of the plate, and in order to avoid calculations and references to tables of logarithms, the scale of the instrument is so arranged as to read the logarithm of the opacity, which is the density. The reason why we prefer to have the results expressed as density is because the density is a measure of the amount of silver deposited, or of the chemical work done by the light.

The instrument pictured in Figs. 1 and 2 consists essentially of a small Bunsen photometer similar to those used for testing the illuminating power of gas, &c. The paper disc with its grease spot is placed in a small cubical chamber. The chamber carries an eye-piece, through which an image of each side of the disc can be viewed in two small mirrors, and so compared. The chamber can be made to slide in a straight line on a support by turning a key connected to one of two pulleys, over which passes an endless cord attached to the chamber. This arrangement is placed within a larger box, the ends of which have apertures through which light is admitted from two powerful petroleum lamps. Corresponding exactly with these apertures, similar apertures are bored into the sides of the small chamber, which admit the light to either side of the Bunsen disc. The dimensions we have adopted are, for the larger box, 12 in. long, 6 in. high, and 4 in. deep. The small chamber is a cube measuring 2 in. inside. We find it necessary to blacken everything within the box except the scales, and it is also important to exclude all extraneous light by means of a screen. The heat of the lamps also very soon injures the woodwork unless it is covered with asbestos cardboard and sheet metal.

The aperture in the left-hand end of the large box we reduce to about  $\frac{1}{4}$  in. diameter by a diaphragm. At this end is placed the plate to be measured, held in position by springs. The hole at the right-hand end of the box is reduced by a rectangular diaphragm,  $\frac{1}{4}$  in. wide and  $\frac{1}{2}$  in. long, the length being vertical. This diaphragm can be reduced in length by moving a taper diaphragm past it.

The instrument is provided with two scales, one fixed, the other moveable, the use and construction of which we will now explain. The fixed scale indicates the position of the disc chamber, and is constructed as follows:—

Suppose that the lamp on the left-hand side gives light of the intensity  $I_1$ , and that on the right-hand side light of intensity  $I_2$ , and that both lamps are equidistant from the centre of the instrument, and that this distance is  $l$ .

Then, when the disc chamber has been moved to a distance  $x$  from the centre of the instrument, so that—

$$(1) \quad \frac{I_1}{(l-x)^2} = \frac{I_2}{(l+x)^2} \text{ or } \frac{I_1}{I_2} = \left(\frac{l-x}{l+x}\right)^2$$

the two images of the disc will be alike. If a plate is now inserted, which reduces the light from the intensity  $I_1$  to intensity  $i$ , then the disc chamber will have to be moved to another place nearer to the plate before the two images of the disc are alike again. Supposing the distance of the disc from the centre of the instrument is now  $y$ , then—

$$(2) \quad \frac{i}{(l-y)^2} = \frac{I_2}{(l+y)^2} \text{ or } \frac{I_2}{i} = \left(\frac{l+y}{l-y}\right)^2$$

By multiplying the two equations we find the fraction, which measures the opacity—

$$\frac{I_1}{i} = \left(\frac{l-x}{l+x}\right)^2 \left(\frac{l+y}{l-y}\right)^2$$

Taking logarithms on both sides, we have, since  $\log. \frac{I_1}{i}$  is the density  $D$  of the plate,

$$D = \log. \left(\frac{l+y}{l-y}\right)^2 - \log. \left(\frac{l+x}{l-x}\right)^2$$

If therefore at the distances  $x$  and  $y$  we write on the scale the values of  $\log. \left(\frac{l+x}{l-x}\right)^2$  and  $\log. \left(\frac{l+y}{l-y}\right)^2$  we can simply read off these logarithms, subtract one from the other, and the result is the density of the plate. For general convenience we use vulgar and not hyperbolic logarithms. In order to avoid all errors arising from the distance of the lamps, we make the apertures in the box small compared with the luminous portion of the flame of the lamps; it can be shown that in that case the distance  $l$  must be measured between the centre of the instrument and the diaphragm.

The following table gives the relative distances of the various points of the scale from the centre of the instrument, at which the logarithms of  $\left(\frac{l+x}{l-x}\right)^2$  have the values 0.1, 0.2, 0.3, &c.,  $l$  being half the distance between the diaphragms.

TABLE I.—FIXED SCALE OF INSTRUMENT.

$\log. \left(\frac{l+x}{l-x}\right)^2$	Distance from Centre of Instrument.	$\log. \left(\frac{l+x}{l-x}\right)^2$	Distance from Centre of Instrument.
0.000	$l \times 0.000$	0.300	$l \times 0.476$
0.100	$l \times 0.057$	1.000	$l \times 0.519$
0.200	$l \times 0.114$	1.100	$l \times 0.560$
0.300	$l \times 0.171$	1.200	$l \times 0.599$
0.400	$l \times 0.226$	1.300	$l \times 0.634$
0.500	$l \times 0.280$	1.400	$l \times 0.667$
0.600	$l \times 0.332$	1.500	$l \times 0.698$
0.700	$l \times 0.382$	1.600	$l \times 0.726$
0.800	$l \times 0.430$	1.700	$l \times 0.752$

Suppose, as in our case, the box were 12 in. long between the diaphragms, then  $l$  is 6 in. The centre of the instrument is marked with zero, and we find from the table that 0.500 must be placed at  $6 \times 0.280$  in. from the centre on both sides of the centre. Similarly other points of the scale are found by means of the table. The scale on both sides of zero is symmetrical. The distances between the points so found are subdivided into equal parts. This is not absolutely necessary, but it is convenient.

The moveable scale (see Fig. 3) is attached to the upper edge of the taper diaphragm, which is used for reducing the amount of light admitted through the rectangular opening. This taper diaphragm is made of sheet metal about 12 in. long and 2 in. wide, out of which is cut a triangular opening about  $10\frac{1}{2}$  in. in length from base to apex, the width of the

base being  $\frac{1}{2}$  in. It is essential that the sides of this triangle be absolutely straight lines. The scale attached to this taper diaphragm is constructed as follows:—From the apex we measure 10 ins. exactly towards the base, this gives the zero point of the scale. The other points of the scale are marked so as to read directly the densities. At any distance  $x$  from the apex the area of the opening and, with it, the intensity of the light will be reduced as  $10:x$ , and the vulgar logarithm of the fraction  $\frac{10}{x}$  is the corresponding density with which the scale is marked. For convenience we append table showing the distances from the apex, at which the figures 0.1, 0.2, 0.3, &c. are to be placed:—

TABLE II.—MOVEABLE SCALE.

Value of Log. $\frac{10}{x}$ .	Distance from Apex.	Value of Log. $\frac{10}{x}$ .	Distance from Apex.
	Inches.		Inches.
0.0	10	0.50	3.16
0.5	8.91	0.60	2.51
1.0	7.94	0.70	2.00
2.0	6.31	0.80	1.58
3.0	5.01	0.90	1.28
4.0	4.00	1.00	1.00

Intermediate points are obtained by subdivision into equal parts.

An index is fixed to the inside of the box over the centre of the rectangular diaphragm pointing to the number to be read. The Figures 1 and 2 will help to make this description clearer.

Two examples will show how the instrument is used.

1. When measuring a small density we move the sliding scale to zero, and the disc chamber to such a position that the images of the Bunsen disc are alike. We then insert the plate to be measured, and without altering the position of the disc chamber slide the moveable scale until equality is restored. The density will then be indicated by the fixed index on the diaphragm scale.

2. In the case of a high density we place the sliding scale to 0, and by placing a piece of opal glass outside the box, between it and the lamp, we reduce the light on the right-hand side until the disc chamber requires to be moved almost up to the right-hand end of the box in order to secure equality of the images. If necessary, we move the lamp further away. When equality is thus secured, we read the number below the index of the disc chamber on the fixed scale. We then insert the plate to be measured, and move the disc chamber to the left until equality is again restored. If that cannot be done by the movement of the disc chamber alone, it can be obtained by using the moveable scale in addition.

Suppose the index stood at 1.100 on the right, and afterwards at 1.55 on the left of zero, then the density would be  $1.100 + 1.55 = 2.65$ .

If the index stood at 1.10 to the right and afterwards at 1.7 to the left, and equality could then only be restored by using the moveable scale as well, and its index pointed to .75, then the density would be  $1.10 + 1.7 + 0.75 = 3.55$ . Higher numbers than 3.55 do not occur in ordinary negatives. A plate, the density of which is 3.55, only transmits  $\frac{1}{355}$ th part of the light it receives.

The general rule for finding the density is: Consider the numbers to the right of zero as negative numbers, those to the left as positive. Subtract the first reading from the second; the result is the density. If the moveable scale be used as well, the amount it indicates must be added.

It will hardly be necessary to say that a plate of density 1 permits  $\frac{1}{10}$  of the light to pass, and that a plate of density 2 permits  $\frac{1}{100}$  of the light to pass, since 1 is the log. of 10, and 2 that of 100.

With this instrument we have obtained fairly accurate results. Analyses of mixtures of Indian ink and water, indigo solution and water, and of many other substances have been made by it. The following analyses are given to show the capabilities of the instrument:—

1. Experiment with Indian ink.—An Indian ink solution was mixed with water in known proportions, and the density of one solution being known, that of the others was calculated. The following table shows the observed and calculated densities. The calculated density is simply proportional to the amount of Indian ink employed.

TABLE III.—EXPERIMENT WITH INDIAN INK.

Indian Ink employed to 100 cc. of Water.	Density calculated.	Density found.	cc. of Indian Ink found.
cc. 5	.240	.240	5.00
10	.480	.500	10.42
15	.720	.750	15.62
20	.960	.950	19.80
25	1.200	1.245	25.90
30	1.440	1.440	30.0
35	1.680	1.665	34.7
40	1.920	1.885	39.3

The greatest error made does not reach 4 per cent. of the total amount, and even better results can be obtained if more than one reading be taken. But this accuracy is quite sufficient for photographic purposes, where, from other causes, still greater errors are liable to arise, as will presently be shown.

Sometimes, when using the instrument for analysing solutions of coloured salts, a peculiar difficulty arises from the different colours of the two images of the Bunsen disc. This is easily overcome by viewing the disc through appropriately coloured glass, red, green and blue glasses being the most useful. The following experiment with indigo solution is representative of one of the most difficult, since dark blue glass was used to view the disc.

TABLE IV.—INDIGO SOLUTION.

Indigo Solution Employed.	Indigo found.	Density calculated.	Density found.
cc. 100	96.9	1.554	1.487
50	50.6	.777	.787
25	24.1	.388	.375
10	10.0	.155	.155

It will be seen again that the results are only accurate within five per cent. of their value.

With regard to the lamps they should be powerful petroleum lamps with duplex burners. The flames should be in planes, at right angles to the axis of the instrument. Very erroneous results are obtained if Argand burners are used. The lamps should be placed close to the diaphragms, and it is advisable to provide a small stage outside the diaphragm to hold coloured glasses, when a substance requires investigation in light of a particular colour.

Captain Abney has also devised an instrument for measuring transparencies. His instrument consists of a Rumford shadow photometer as indicator, and of a revolving sector, which can be closed or opened whilst revolving, as a measure of the transparency. Apart from the fact that a Bunsen disc is more sensitive than the shadows, there is a fallacy in the assumption that the amount of light, which passes through a revolving sector is proportional to the angle to

which the sector is opened. Experiments made for the purpose show that the amount of light passing through a revolving sector is more correctly represented by a formula—

$$I_s = 1 \frac{\phi}{360} + C.$$

where  $I_s$  is the light transmitted by the sector,  $I$  the intensity falling upon the sector,  $\phi$  the angle of opening and  $C$  a constant, which depends upon the relative position of the lamp, the sector and the screen, and is, in fact, due to the semi-shadow on both edges of the sector openings. The error caused by this constant is small with plates of low density but it rises to over 100 per cent. with plates of high densities, which renders the results utterly untrustworthy.

We have thought it necessary to give this lengthy description of our instrument, since we consider it a very important one; it is for photographic experiments as indispensable as the balance is in analysis. The instrument is capable of other applications; its indications can always be translated into weights by simply multiplying them with a factor. It is, therefore, capable of applications in analysis.

### III.—DEVELOPMENT.

There is a generally accepted belief among photographers that a great amount of control can be exercised in development over the density and the general gradations of a negative, and in this respect alkaline pyrogallol enjoys a special reputation. On this account we have chosen this developer for the following series of experiments, except where otherwise stated. These experiments conclusively show that the only control the photographer has over development lies in securing a greater or less density of image (the former often only at the expense of fog), and that he has no control whatever over the gradations of the negative.

The plan we have adopted in carrying out these experiments is to subject *pieces of one and the same plate* to the varying conditions the influence of which, on the density or the gradation, is the subject of our investigation. A precaution we have always taken, except in our earliest experiments, is never to develop a piece of a plate which has been exposed to the light without simultaneously submitting to the same developer a piece of the same plate which has *not* been exposed, and which we term the "fog strip." The object of this precaution is to ascertain exactly how much of the resulting density is due to the action of the light and how much is due to incidental fog, including therein, fog inherent in the plate or caused by injudicious development, and also the density due to glass and gelatin.

In the following series of experiments, made to ascertain the influence of time, of development, and composition of the developer on the density, we covered up one half of a plate and exposed the other half to a standard light, as will be presently more fully explained. After exposure we cut up the plate in such a way that each piece included a portion of the unexposed and a portion of the exposed plate. Each strip was then developed, such modification in time of development or composition of developer being made as formed the subject of the investigation. The resulting densities were then measured after fixing, washing, and drying,

#### Time of Development.

*Experiment 1.*—Plate: "Wratten Ord." Exposure: ?

Developer, 100 cc. contain  $\begin{cases} 0.085 \text{ g. NH}_3, \\ 0.400 \text{ pyrogallol.} \\ 0.250 \text{ NH}_4\text{Br.} \end{cases}$

#### Results.

Time of development.....Minutes	2.5	5.0	7.5	10.0	12.5	15.0
Densities produced ..	.183	.543	.793	1.160	1.110	1.117
Percentage .....	15.6	46.0	67.8	99.1	94.0	100.0

*Experiment 2.*—Plate: "Wratten Ord." Exposure = 60 C.M.S.

Developer, 100 cc. contain  $\begin{cases} 0.162 \text{ NH}_3, \\ 0.342 \text{ Pyro.*} \\ 0.228 \text{ NH}_4\text{Br.} \end{cases}$

Time of development Minutes..	1.25	2.5	5	10	15
Density exposed plate....	.775	1.175	1.725	2.275	2.475
Density unexposed plate .	.155	.270	.510	.590	.790
Density due to light .....	.620	.905	1.215	1.685	1.685
Percentage developed ....	36.8	53.7	72.1	100	100

*Experiment 3.*—Plate: "Wratten Ord." Exposure = 20 C.M.S.

See Diagram No. 1. Developer, 100 cc. contain:—

$\begin{cases} 0.162 \text{ NH}_3, \\ 0.342 \text{ Pyro.} \\ 0.228 \text{ NH}_4 \text{ Br.} \end{cases}$

Time of development. Minutes	2.5	5	7.5	10	15	20
Density exposed plate .....	.670	.965	1.245	1.420	1.755	1.945
Density unexposed plate ..	.200	.345	.415	.505	.575	.710
Density due to light.....	.470	.620	.830	.915	1.180	1.235
Percentage developed.....	38.0	50.2	67.2	74.1	95.5	100

These experiments show that the total density grows with the time of development, but that the density due to light reaches a limit in about 15 minutes. The continued growth of the total density is due to the action of the developer upon the bromide of silver which had not been affected by the light.

#### Variation of Pyrogallol.

*Experiment 4.*—Plate: "Wratten Ord." Exposure ?

Developed each strip four minutes in a developer, containing in 100 cc =  $\begin{cases} 0.1156 \text{ NH}_3 \\ 0.2000 \text{ NH}_4\text{Br} \end{cases}$

Pyrogallol.....grms..	0.08	0.16	0.32	0.64

Density due to light...	.415	.645	.870	1.085	1.015	.935

\* Sulpho-pyrogallol equivalent to Pyro.

From these results we gather that an excess of pyrogallol beyond a certain limit tends to retard development and the production of density. This limit appears to be the equivalent of pyrogallol necessary to convert the ammonia into tribasic pyrogallate,  $C_6H_3(O\dot{N}H_4)_3$ .

A similar experiment is here given, made with "sulpho-pyrogallol" compounded with sodium sulphite and citric acid. It will be evident that the presence of the acid, by neutralising the ammonia, is responsible for the much more marked falling off in density.

*Experiment 6.*—Plate: "Manchester Slow." Exposure = 40 C.M.S.

Developed 4 minutes, 100 cc. =  $\begin{cases} 0.162 \text{ NH}_3 \\ 0.228 \text{ NH}_4\text{Br} \end{cases}$  and "sulpho-pyrogallol" corresponding to  $x$  grms. pyrogallol.

The general result of these experiments is that the addition of ammonia, up to a certain extent, increases the density in a given time, but that the amount of ammonia which can be added without giving rise to fog, and without simultaneously adding bromide, is very limited. The so-called accelerating action of ammonia being due almost

entirely to its solvent action on bromide of silver, which, if the ammonia is increased sufficiently, results in greatly diminishing the density.

The following table shows the solubility of silver bromide in very dilute ammonia, such as is used for development of plates:—

100 cc. of dilute ammonia containing:—

1.105 grms. $\text{NH}_3$ dissolve	0.0576 AgBr
.555 " "	0.0206 " "
.462 " "	0.0100 " "
.0897 " "	0.0052 " "

The last two solutions represent the extreme concentrations usually employed by photographers for development.

If, to any of these solutions of silver bromide in ammonia bromide of ammonium be added, an immediate precipitate of bromide of silver is the result. The so-called accelerating action of ammonia, and the retarding action of ammonium bromide, are probably due entirely to this solvent action of the one, and the anti-solvent action of the other of these two reagents. The rapid production of fog when ammonia is increased is due to the fact that when pyrogallol solution is added to an ammoniacal solution of bromide of silver, the silver in solution is precipitated immediately in the metallic state.

The following experiments show the influence of

#### Variation of Ammonium Bromide.

*Experiment 10.*—Plate: "Wratten Ord." Exposure?

It is clear that development in both experiments was entirely prevented in these four minutes when the amount of bromide was about 10 times that of ammonia present.

It also appears from our experiments that a rational developer would consist of a decinormal solution of ammonia, containing so much pyrogallol and ammonium bromide as would correspond with the formula—

We have represented many of these results in the form of diagrams. It will be interesting just to point to diagrams Nos. 1, 3, and 4, to show the great amount of action which the alkaline developer may have on the bromide of silver, although it has never been exposed.

This disagreeable property is common to all alkaline developers, and it renders them unsuitable for scientific investigations. In all our important work we use exclusively the ferrous oxalate developer for the reason that it attacks unexposed bromide of silver so slowly, that within one hour

and even more, no appreciable density can be developed upon a really good plate. Nor does its action vary much with its composition. The addition or omission of bromide from the constitution of this developer does not seem to have any great influence, and a greater or less concentration of the reagents within considerable limits does not affect its action; indeed, we have not found any variation to arise from alterations in its composition, excepting the length of time needed for completion of development.

The following table shows how the density of an exposed plate grows as the time of development is prolonged from five minutes to one hour.

*Experiment 12.—Ferrons Oxalate.*

Time.	Density exclusive of Fog.				
	I.	II.	III.	IV.	V.
Minutes.					
5	.365	.350	..	..	.215
10	.525	.430	..	..	.305
15	.615	.550	.735	.570	.410
20	.615	.575	..	..	.420
25	.700	.650	..	..	..
30	.700	.660	.860	.670	.450
45	..	..	1.000	.715	.545
60	..	..	..	.740	..

Columns I. and II. are the results obtained upon the same plate, one (I.) portion of the strips developed in a developer consisting of 4 parts of a saturated solution of potassium oxalate, mixed with 1 part of a saturated solution of ferrons sulphate, the other (II.) portion of the strips developed in the same developer diluted with an equal volume of water. Columns III. and IV. represent other experiments, the plates being developed with the saturated solution. Whilst I. to IV. were developed with a small amount of bromide of potassium added to the developer, No. V. was developed without bromide. In not one instance did the density of the unexposed portions of the plate amount to more than 0.098, which is the density due to clear glass and gelatin. That ferrons oxalate does not, however used, attack silver bromide which has not been exposed to light is a most valuable and characteristic property of this developer.

An important result of this series of experiments is that the density reached is dependent upon the time of development as well as upon the exposure of the plate. The time it takes to reach a given density varies much with the gelatin employed in making the emulsion and the age of the plate. But with each plate it obeys a certain law, which is more or less clearly visible in every one of the five experiments. The density grows rapidly at first, its growth becoming slower as time advances, and finally tends to a limit. Each experiment is, taken by itself, liable to many errors; but by reducing every experiment to the densities obtained in No. IV., in simple proportion, the following tabulated series of numbers is obtained:—The columns marked I., II., &c., are the reduced densities of the corresponding columns of experiment 12. The column marked "Mean" shows the arithmetical mean for any period of development obtained from the five series. The column "Calculated" is obtained by means of a formula based upon the idea that the number of particles of bromide of silver affected by the light is greatest in the front layer of the film and decreases in geometrical progression as each succeeding layer of the film is reached, an idea which will be better appreciated when we have explained the action of the light upon the film. This idea expressed algebraically leads to the formula—

$$D_t = D(1 - \alpha^t)$$

where  $D_t$  is the density after  $t$  minutes development,  $D$  the limit of density reached by very prolonged development,

and  $t$  the time of development,  $\alpha$  is a fraction depending upon the nature of the film, concentration of developer, temperature, &c. The constants for the series of figures below are  $D = 0.720$ ,  $\alpha = 0.9015$ .

Time.	Recalculated.—Densities.					
	I.	II.	III.	IV.	V.	Mean. Calculated.
Min.						
5	.349	.350	..	..	.298	.332 .290
10	.502	.460	..	..	.423	.462 .464
15	.588	.550	.569	.570	.561	.569 .568
20	.588	.575	..	..	.583	.582 .628
25	.670	.650	..	..	..	.660 .665
30	.670	.660	.615	.670	.625	.645 .687
45	..	..	.715	.715	.715	.715 .713
60	..	..	..	.740	..	.740 .719

The relation of the calculated figures to the experimental data is best seen in diagram No. 6.

A very important conclusion can be shown to proceed from the formula representing the course of development.

If on any one plate two exposures are given, one of which would ultimately yield density  $D_1$  and the other  $D_2$ , and if this plate were developed for a time  $t$ , then two densities,  $d_1$  and  $d_2$ , would result such that:—

$$d_1 = D_1(1 - \alpha^t)$$

$$d_2 = D_2(1 - \alpha^t)$$

and it will be seen that on dividing these equations,

$$\frac{d_1}{d_2} = \frac{D_1}{D_2}$$

the resulting ratio is independent of the time of development, and is equal to the ratio of the ultimate densities which would be reached, so that the gradation of negatives appears to be independent of the time of development.

#### IV.—GRADATION.

The above experiments have shown that with a well-balanced developer there is a limit to density, which depends upon the action of the light, and that, so far, the only control the photographer has lies in deciding whether he will reach that limit or not.

It also became evident that if two different densities be developed upon the same plate to their extreme limits, the ratio existing between these limits must depend solely upon the action of the light. The question we have now to consider is whether it is possible by any modification of development to influence this ratio, and whether this same ratio exists at all stages of development.

In making these experiments, the source of light we have adopted is a standard candle placed at 1 metre distance from the plate. We then produce a number of gradations upon the plate by exposing different portions of it to the light for different periods of time, always leaving one portion of the plate unexposed.

In order to show that the length of time of development does not affect the ratio of densities among themselves, but increases every density by proportional amounts, we give the following experiments, made with various plates, ferrons oxalate being the developer used. The tables show the densities obtained, their ratio among themselves, and the ratios of the two corresponding densities obtained by long and short development.

All densities are given exclusive of fog (the density of unexposed plate being subtracted from density of exposed plate).

## Experiment 13.—Gradations. Ferrous Oxalate.

Plate used.	Exposure, C.M.S.	Short Development, 4 Minutes.		Long Development, 12 Minutes.		Ratio, $\frac{D_2}{D_1}$	Remarks.
		Density $D_1$ .	Ratio.	Density $D_2$ .	Ratio.		
Ilford Red Label. (1.)	10	·775	1·0	1·260	1·0	1·63	Greatest error, $\pm$ 2·4 per cent.
	20	1·000	1·20	1·660	1·31	1·66	
	40	1·180	1·52	1·96	1·55	1·66	
	80	1·250	1·61	2·08	1·65	1·60	
				Mean.....		1·64	
Wratten's Drop shutter. (2.)	10	1·17	1·0	1·74	1·0	1·50	Greatest error, $\pm$ 3·4 per cent.
	20	1·67	1·42	2·37	1·36	1·42	
	40	2·06	1·76	2·91	1·67	1·41	
	80	2·26	1·93	3·33	1·91	1·47	
				Mean.....		1·45	
"United Kingdom." (3.)	10	·160	1·0	·275	1·0	1·70	Greatest error, $\pm$ 5 per cent.
	20	·313	1·95	·485	1·76	1·55	
	40	·518	3·23	·830	3·01	1·60	
	80	·703	4·39	1·145	4·14	1·63	
				Mean.....		1·62	

The greatest errors are comprised within those limits within which our method of measuring densities is only reliable.

The results clearly show that the ratio of densities is given by the light alone, and is not affected by the time of development, a fact quite in accordance with the conclusions previously arrived at.

This ratio, we find, is altogether unalterable. No modifications we have made in developers or in development has

ever seriously disturbed this ratio of the densities. We quote the following few experiments in support of this statement.

*Experiment 14.*—The plate, a "Manchester Slow," having received three different exposures was cut into four portions, two were developed with hydroquinone, and two with eikonogen for different lengths of time. The densities are given exclusive of fog which, with both developers, was very considerable:—

Developer.	Exposure, C.M.S.	Short Develop.		Long Develop.		Ratio $\frac{D_2}{D_1}$	Remarks.
		Density $D_1$ .	Ratio.	Density $D_2$ .	Ratio.		
Hydroquinone.	10	·485	1·0	·785	1·0	1·61	Short time = 2·5 m. Long time = 7·5 m. Mean ratio, 1·55. Greatest error, 4 per cent.
	20	·875	1·80	1·385	1·76	1·58	
	40	1·450	3·0	2·120	2·70	1·47	
Eikonogen.	10	·310	1·0	·580	1·0	1·87	Short time = 4 m. Long time = 12 m. Mean ratio, 1·79. Greatest error, 4·4 per cent.
	20	·560	1·81	·980	1·7	1·75	
	40	·905	2·92	1·600	2·76	1·76	

*Experiment 15* shows that the same result is obtained with pyrogallol development. Plate used: "Manchester Slow." Densities exclusive of fog.

Exposure, C.M.S.	Developed, Three Minutes. Ammonia added at once.		Developed, 18 Minutes. Ammonia added in Six Doses every Three Minutes.		Ratio $\frac{D_2}{D_1}$	Remarks.
	Density $D_1$ .	Ratio.	Density $D_2$ .	Ratio.		
10	·385	1·0	·420	1·0	1·09	Mean Ratio, 1·15.
20	·770	2·0	·850	2·0	1·10	Greatest error, 5 per cent.
40	1·095	2·84	1·315	3·1	1·19	
80	1·455	3·7	1·735	4·0	1·21	

*Experiment 16* is important because it contradicts emphatically the belief that gradations of an over-exposed negative can be altered by using greater amounts of bromide. Plate: "Manchester Slow."

Exposure. C.M.S.	Developed, Four Minutes, 100 cc. = 0.22 NH <sub>4</sub> Br.		Developed, 12 Minutes, 100 cc. = 0.66 g. NH <sub>4</sub> Br.		Ratio $\frac{D_2}{D_1}$	Remarks.
	Density $D_1$ .	Ratio.	Density $D_2$ .	Ratio.		
10	.440	1.0	.485	1.0	1.10	Mean ratio, 1.15.
20	.840	1.91	.955	1.98	1.15	Greatest error, 4.3 per cent.
40	1.200	2.73	1.440	2.97	1.20	
80	1.625	3.70	1.900	3.90	1.16	

*Experiment 17.*—For this experiment a "Wratten Ordinary" plate received four different exposures. It was then cut into four portions, and each portion was developed with a different developer. The result is extremely interesting and important, since it shows that the ratio between the various densities is identically the same whatever developer is employed, except in the case of eikonogen, in which the ratios are a little different. We shall recur to this difference in another place.

#### TIME OF DEVELOPMENT DIFFERENT FOR EACH DEVELOPER.

Exposure.	Ferrous Oxalate.		Pyrogallol.		Hydroquinone.		Eikonogen.	
	Density	Ratio.	Density	Ratio.	Density	Ratio.	Density	Ratio.
C.M.S.								
10	.310	1.0	.320	1.0	.440	1.0	.300	1.0
20	.535	1.7	.550	1.7	.695	1.7	.470	1.6
40	.810	2.6	.805	2.5	1.000	2.4	.645	2.2
80	1.080	3.5	1.005	3.1	1.400	3.4	.820	2.7

These experiments all confirm the statement that the gradations of a negative, as expressed by the ratios of the densities, are independent of time of development, cannot be affected by alterations in the composition of the developers, and are almost identically the same whatever developer is employed. We are thus driven to the conclusion that the photographer has no control over the gradations of the negative, the ratios of the amount of silver deposited on the film being solely dependent upon the exposure. The photographer has the power to increase the total density by prolonged development, but by no means at his disposal can he alter the ratios existing between the amounts of silver reduced in the various parts of the negative; they are regulated entirely by the exposure.

These ratios are not even altered by intensification after development, as is shown by the following results:—

#### INTENSIFICATION.

*Experiment 18.*—Plate "Wratten Ordinary" exposed and developed with ferrous oxalate, measured and afterwards intensified and measured again.

Exposure.	Before Intensification.		After Intensification.		$\frac{D_2}{D_1}$
	Density $D_1$ .	Ratio.	Density $D_2$ .	Ratio.	
10	.31	1.0	.30	1.0	1.33
14	.50	1.61	.91	1.5	1.82
20.5	.67	2.16	1.30	2.16	1.94
29.3	.86	2.77	1.71	2.85	1.98
41.9	1.03	3.32	2.15	3.5	2.08
60	1.30	4.19	2.54	4.2	1.96
					Mean, . . . . 1.95

It will be seen that the process of intensification has almost exactly doubled the amount of silver on the plate. Almost the same result was found in the following experiment:—

*Experiment 19.*—Similar to last experiment.

Exposure.	Before Intensification.		After Intensification.		Ratio $\frac{D_2}{D_1}$
	Density $D_1$ .	Ratio.	Density $D_2$ .	Ratio.	
10	.260	1.0	.475	1.0	1.82
20	.460	1.8	.850	1.8	1.85
40	.700	2.7	1.270	2.6	1.81
80	.950	3.6	1.700	3.6	1.79
					Mean, . . . . 1.82

In this case intensification did not quite, but very nearly, double the amount of silver in each density, but the ratio existing between the several gradations is again not affected at all.

We see therefore, that, whatever may have been the mode of development employed, and whether intensified or not, the ratios of densities are characteristic of the action of the light, and can be alone relied on in investigations respecting the action of the light on the sensitive film.

#### REDUCTION.

There is only one process known to us so far, which will totally alter the ratios existing between the deposits of silver on a negative, viz., the process of reduction, that process consisting in immersing the developed plate into a solution of potassium ferrieyanide and sodium thiosulphate (hyposulphate). This process so alters the ratios that photographers ought to use it very cautiously.

*Experiment 20.*—Plate exposed, measured, and reduced by immersion in potassium ferrieyanide and sodium thiosulphate.

Exposure.	Before Reduction.		After Reduction.		Ratio $\frac{D_1}{D_2}$
	Density $D_1$ .	Ratio.	Density $D_2$ .	Ratio.	
10	.410	1.0	.620	1.0	20.5
20	.655	1.6	.130	6.5	5.0
40	1.010	2.46	.365	18.2	2.7
80	1.450	3.5	.680	34.0	2.1

#### V.—ACTION OF LIGHT ON SENSITIVE FILM.

Our investigations have not only revealed the fact that one single density taken by itself is not characteristic of the exposure which the sensitive film received, since the density may be partially due to "fog," or may not be developed to its extreme limit, but the experiments have

Fig. 1

*Hurter & Driffield's Apparatus for Measuring Density of Negatives.*

*Fig. 2.**Fig. 3. Sliding Scale.*

also clearly shown that the ratio of two densities, exclusive of fog, is a function of the action of the light on the plate. It will be noticed that in all these experiments the exposures given varied between 10 seconds and 80 seconds, and the source of light was always a standard candle placed exactly one metre off the plate. If we tabulate the ratios found between the 10 seconds and 80 seconds exposures in these experiments we see at once that the ratio, though constant for one particular plate, is very different for different plates.

Name of Plate.	Ratios of Densities for		Experiment No.
	Exposures 10'' = 4.	Exposures 80'' = 8.	
Hford "Red Label" .....	1.53	1.63	13
Wratten "Dropshutter" ..	1.71	1.92	13
"United Kingdom" .....	3.12	4.27	13
"Manchester Slow" .....	2.97	3.82	15
Do. Do. ....	2.85	3.80	16
Do. Do. ....	2.84	..	14

Own make .....	Batch A. ....	Exposures	160'' .....	8.00
	" A. ....	"	20'' .....	"
	" A. ....	"	240'' .....	5.30
	" A. ....	"	360'' .....	"
			1440'' .....	3.00
			180'' .....	"

The ratio is for the same exposures, smaller for rapid plates than for slow plates, but even with the same plate, the ratio between two densities varies for exposures which bear the same ratio to each other, but are different in absolute value as is seen from the experiments given in the above table, and made with plates prepared by ourselves.

It is certain, therefore, that the ratio between two densities depends not only on the ratio of the exposures, but also on the sensitiveness of the plate and the absolute values of the exposures. The following investigations were made to discover the connexion existing between exposure, sensitiveness, and density produced.

**Unit of Exposure.**—For these investigations it was necessary to adopt a standard unit of exposure. As unit of light we have chosen the intensity of a standard candle at one meter distance, and as unit of time the second, so that our unit of exposure is the product of the intensity of the standard candle at one meter distance and the second, and we call this unit of exposure one "candlemeter-second." We find for experimental purposes, with plates of average speed it is an excellent unit, easily procured, and of sufficient constancy to permit of satisfactory repetitions of experiments. There are a few precautions necessary to ensure uniform results. The flame of the candle cannot be relied on until it has settled to a height of nearly 45 mm. measured from the top of the spermaceti to the top of the flame, as shown in Fig. 4. The candle must be protected against draughts, and this is best done by placing it within a black box having one side open. This also prevents the illumination of bright objects on the working table and consequent reflections. The candle should be extinguished by an extinguisher and kept covered up while not in use.

As regards measuring time of exposures we use a chronograph watch, or a metronome for short exposures, but we find that errors of exposure become too great if less than 10 seconds are measured. If we wish to give shorter exposures than 10 candlemeter-seconds (C.M.S.) we place the standard candle two meters off, thus reducing its intensity to one quarter.

It is scarcely necessary to say that we have carefully ascertained that within such limits of exposures as our experiments embrace it is immaterial whether an exposure be made with a light of  $\frac{1}{4}$  candlemeter for 40 seconds or a light of one candlemeter for 10 seconds. We have also

proved by experiment that, as far as the ratios of densities are concerned, they remain constant, whether the exposure be made with a candle, with a petroleum lamp or with daylight, so long as the product of intensity of light and time of exposure be the same. The intensities of such different sources of light cannot however for this purpose be compared by the ordinary Bunsen photometer, but must be compared by photographic experiments. But with careful work even single densities can be reproduced with tolerable accuracy. For instance, on three separate days we obtained on three separate plates of the same batch by carefully measuring the time, both of exposure and of development, densities 0.750, 0.730, and 0.720 respectively. Four different standard candles gave upon one plate in 10 seconds the following densities: 0.490, 0.490, 0.500 0.480.

With the standard candle we investigated, in the first place, the general effect of prolonged exposure on the density, *i.e.*, we ascertained how much silver was reduced by different exposures.

**Experiment 21.**—A "Manchester Slow" plate exposed, developed with ferrous oxalate and measured, gave:—

Exposure C.M.S.	Density.	Difference.	Exposure C.M.S.	Density.	Difference.
0.625	.045	..	80	1.010	.255
1.25	.055	0.010	160	1.270	.260
2.50	.085	0.030	320	1.555	.285
5.00	.175	.090	640	1.885	.330
10.0	.250	.075	1280	2.088	.203
20	.460	.210	2560	2.262	.174
40	.755	.295	5120	2.352	.090

It will be seen that, every time the exposure is doubled, the density increases, at first slowly, then considerably, and (disregarding errors of experiment) from 40 C.M.S. up to 1280 C.M.S. every time the exposure is doubled, nearly an equal addition to density is the result, the addition to the density being on an average 0.266, but after an exposure of 1280 C.M.S. further doubling produces less and less increase in density. The first few densities are too small to admit of accurate measuring.

This series of results is represented graphically on diagram No. 7, the exposures being chosen as abscissae, the densities as ordinates; from this diagram it will be seen at once how rapidly densities grow at first as exposure is increased, and how slowly at last the densities tend towards a limit.

The following series of exposures is carried still further in order to ascertain the character of the curve representing the action of the light on the silver bromide, and to learn, if possible, something of the limit towards which the curve tends.

**Experiment 22.**—

Exposures C.M.S.	Densities.	Difference.	Exposures C.M.S.	Densities.	Difference.
1	.060		1024	2.085	+ 450
2	.160	+ 100	2048	3.115	+ 130
4	.340	+ 180	4096	3.280	+ 165
8	.500	+ 160	8192	3.405	+ 125
16	.715	+ 215	16384	3.508	+ 103
32	.910	+ 225	32768	3.471	- 0.034
64	1.345	+ 405	65536	3.280	- 0.194
128	1.875	+ 530	131072	3.128	- 0.162
256	2.200	+ 415	262144	2.920	- 0.208
512	2.535	+ 245	524288	2.444	- 0.456

This series of results could not be graphically represented to advantage by choosing exposures as abscissæ since they vary from one candlemeter-second to over half a million. But it is evident that prolonged exposure gradually reduces the density attainable after development.

The graphic representation of experiment 22 on the same scale as experiment 21 would require a diagram about 500 times as long as diagram No. 7, and nothing of any value would be learnt from such a diagram.

What we really wish to ascertain is whether it is possible to produce a theoretically perfect negative, such as was defined, and what the connexion is between the densities and the exposures.

If in any part of the curve of densities, as represented in diagram No. 7, the densities were proportional to the logarithm of the exposures, we should discover that portion of the curve if, instead of choosing the exposures as abscissæ, we used the logarithms of the exposures as abscissæ. This is easily done when the exposures progress, as they always do in our experiments, in a geometric series. We have only to mark every new exposure equi-distant from the previous one as abscissæ. In this manner the results of experiment 22 are plotted in diagram No. 8.

It will be perceived that the curve now consists of four distinct branches. It proceeds from exposure 1 in almost horizontal direction, ascends slowly to exposure 16, from thence it proceeds almost in a straight line to exposure 2048, when the growth of densities becomes slow. The densities reach their maximum at exposure 16,384, and from thence the curve returns, the densities diminishing slowly with increased exposures.

We accordingly distinguish four different periods of exposures. The first period we term the period of "under exposure;" it is comprised in the first curved portion. The second period, that during which the curve is almost a straight line, we call the "period of correct representation." The third period is that during which the curve is again strongly bent as far as its maximum; this is the period of "over-exposure," and the last portion of the curve we term the period of "reversal."

1. *Period of Under-exposure.*—During this period the ratios between two densities are at first accurately equal to the ratio of the corresponding exposures. It is very difficult to study this portion of the curve accurately, owing to the short exposures which it demands, but still more owing to the small densities which this period yields, and which are difficult to measure. By making very slow emulsions, we have, however, succeeded in showing clearly that at first the amount of silver reduced is proportional simply to the exposure. Thus, a plate made by ourselves, with pure bromide of silver, gave the following results:—

Exposure, 20 C.M.S.	Density, .125 or 1.
" 160 "	" 1.055 or 8.4.

The ratio between the densities being very nearly 8, the ratio of exposures.

Again, a "United Kingdom" plate gave the following results:—

Exposure, 2.5 C.M.S.	0.160.	Ratio, 1.
5.0 C.M.S.	0.313.	1.95.

A very slow "Manchester" plate gave the following results:—

1 C.M.S.	0.260.	Ratio, 1.
2 C.M.S.	0.550.	2.1.

But of course there is no definite point which marks the end of this period and the beginning of the next. But it is from this period that we learn that, for short exposures, the amount of silver reduced is directly proportional to the exposure.

*Period of Correct Representation.*—The second period of exposures we have thus named because during this period a plate is capable of giving a negative differing as little as possible from that which, at the beginning, we defined as theoretically perfect. That definition demanded that the densities of the negative should be proportional to the logarithms of the exposures which produced them. It is

characteristic of this period that the densities are proportional to the logarithms of the exposures. This is shown on diagram No. 8, where the densities are the ordinates, the logarithms of exposures are abscissæ, and the period of correct representation a straight line. We have measured densities of dozens of plates falling within this period, and we find them all to conform to this very simple linear equation—

$$D = \gamma [\log. I.t \pm C],$$

D being the density,  $\gamma$  a constant depending on time of development,  $I.t$  the product of intensity of light and time, i.e., the "exposure," and  $C$  a constant depending upon the speed of the plate. As we shall give further detailed proof of this, we will here merely insert one example of a plate, the constant  $C$  of which is zero, it is Plate 2 of experiment No. 13. That plate gives the following results with equation:—

$$D = 1.75 \times \log. \text{exposure.}$$

Exposure.	Density found by Experiment.	Density Calculated.
10	1.74	1.75
20	2.37	2.27
40	2.91	2.75
80	3.33	3.30

Many similar examples will be quoted presently.

We have thus arrived at the answer to the question, can negatives be produced such as we defined to be theoretically perfect? And this answer is, they *can* be produced, but only by so carefully adjusting the time to the intensity of the light, that the exposures may fall within that period of correct representation. No variations whatever in development will correct an under- or over-exposure.

*Period of Over-exposure.*—Little need be said about this period. As the curve tends to become parallel to the axis of abscissæ it is clear that when exposures fall within this period, shadows and high lights will all be represented by densities which are almost equal. There will be no contrasts. In the first period of under-exposure the contrasts are too great; here they are too small.

*Period of Reversal.*—This period we have named the period of reversal because within this period happens that peculiar phenomenon, the transformation of the negative into the positive, the "solarisation," "reversal," &c. It is easy to understand how the negative becomes a positive. Whilst the deep shadows still act upon the plate increasing the density the high lights have passed their maximum and their densities grow less and less. The more the exposure is prolonged the less dense the high lights become, the shadows exceeding them in density. It is quite easy to observe this phenomenon of reversal with a powerful petroleum lamp or gas burner, or to produce by direct contact printing a secondary negative, instead of a positive, from the original negative, by about 15 to 20 minutes exposure at 6 in. distance from the light. When, in the camera, exposure is prolonged, it is well known that a positive is obtained instead of a negative. It has been stated by Jansen that a secondary negative and a secondary positive, can be obtained by prolonging the exposure still further. We have not, however, been able to verify this statement, and we believe it to be erroneous. Our investigations show that the density tends to a limit, and a picture produced by prolonged exposure in the camera is gradually lost in a uniform veil of fog, though it is still visible even after a three days' exposure.

A "United Kingdom" plate received various prolonged exposures, with the following results:—

		Difference.
75,000 C.M.S. gave density	1.415	
150,000 " "	1.111	.304
300,000 " "	.970	.141
600,000 " "	.925	.045

A piece of the same plate exposed to direct daylight for 90 minutes (about six million C.M.S.) gave a density 1.200. From this it appears to us that there is an equilibrium established between the action of the refrangible and less refrangible rays.

The period of reversal is, theoretically, exceedingly interesting, and deserves further careful study, but the reversing action is so slow, and requires such enormous exposures, that it does not need to be considered from a practical point of view, and we shall disregard it entirely for the present. The three first periods, that of under-exposure, that of correct representation, and that of over-exposure are the only practically interesting portions of the curve. We have already stated that, during the first period, the ratio of densities is equal to the ratio of exposures, *i.e.*, the amount of bromide of silver reduced is proportional to the exposure, whilst, during the second period, the density only grows in proportion to the logarithm of the exposure. It almost ceases to grow during the third. Of course, these assertions are only two approximate statements of one single law connecting the densities with the exposures.

All photo-chemical investigations which have hitherto been made have proved that the amount of chemical action is proportional to the "exposure" (*i.e.*, the product of intensity of light and time). The sensitive film of the photographic plate forms no exception to this general law, and we take it as a fundamental truth that the amount of action upon the plate is, at any moment of the exposure, proportional to the energy which the plate receives at that moment. During the first period, when the surface, or chiefly the surface of the film, is acted upon, the results of the investigations have shown this to be true accurately. But when the action of the light upon particles of bromide of silver below the surface has to be considered, the question arises, how much of the light which impinges on the surface really reaches those particles?

Of the rays of light which impinge upon the surface of the sensitive plate, some are reflected and some pass right through the plate. If one sensitive plate be exposed to light behind another, it will be found that it also is affected.

The energy of the reflected and transmitted light cannot, obviously, play any part in the molecular work to be done in the film. It is useless photographically.

The light absorbed in the film is the only light which contributes towards the formation of the "latent image," but not even the whole of the light which is absorbed does useful work. It can be proved experimentally that a plate which has received such an exposure as to yield maximum density on development, absorbs exactly as much light as a plate which has not been exposed at all, yet the light absorbed by a plate already so exposed obviously contributes nothing towards increase of density.

From this it is clear that the light absorbed by a particle of silver bromide, which has already received sufficient energy to bring it into that condition in which it is capable of development, is useless.

It will, therefore, be evident that, of the light impinging upon the plate, there is only one portion useful, *viz.*, that which is absorbed by unaltered silver bromide, the light reflected, the light transmitted, and the light absorbed by particles of silver bromide already changed, being altogether useless.

The amount of work done at any moment of the exposure is therefore proportional to the amount of energy received by the unaltered silver bromide only.

It is very easy to state this proposition mathematically, and thus find the law which connects the densities with the exposures.

If the intensity of the light (with respect to chemically active rays) is  $I$ , and the fraction of the light reflected from the surface of the film is  $\alpha$ , then the amount  $(1-\alpha) I$  enters the film. If the film contains, at the moment we are considering,  $x$  particles of silver bromide per unit area, which are already changed, then the transparency of the plate with respect to the changed particles is  $\epsilon^{-kx}$ , *i.e.*, this is the amount of light which passes the particles already changed. If from this amount we deduct the amount of light which passes *all* the particles of silver, changed or unchanged, the difference represents the amount of light

absorbed by the silver bromide not yet affected. Now the light which passes all the particles of silver, if there are  $a$  of them per unit area, will be measured by the transparency of the plate *viz.*,  $\epsilon^{-ka}$ . Deducting this from  $\epsilon^{-kx}$  and multiplying the difference with the total amount of light entering the film will give the mathematical expression for the amount of light which, at the moment we are considering, can do useful work; this amount is:  $(1-\alpha) I (\epsilon^{-kx} - \epsilon^{-ka})$ . If this expression is multiplied by the short time of exposure  $dt$ , it will represent the amount of useful energy conveyed to the plate during that time.

Suppose it requires an amount of energy  $e$  to change one particle of silver bromide into the condition capable of development, then the number of particles  $dx$  so changed during the time  $dt$  will be

$$(1.) \quad dx = \frac{1}{e} (1-\alpha) [\epsilon^{-kx} - \epsilon^{-ka}] dt.$$

This is the complete mathematical expression of the idea that it is only that portion of the light which is absorbed by unchanged silver bromide, which contributes to the growth of density.

By integration of equation (1), and by substitution of the symbol  $O$  for  $\epsilon^{-ka}$ , we find that the density of the "latent image" (before development) is

$$D = \log_e [O - (O-1) \beta^{k(1-\alpha)} \frac{It}{e}]$$

where  $\beta$  is a fraction, the hyperbolic logarithm of which is  $-\frac{1}{O}$ .  $O$  is simply the opacity of the plate to the chemically active rays before exposure.

In this derivation of the connection between the density  $D$  and the exposure  $It$ , two assumptions have been silently made which need explanation. The coefficient of absorption,  $k$ , has been assumed to have the same value both for the altered and the unaltered silver bromide. We have, however, experimentally ascertained that this is a fact. It can be easily proved photographically. If, behind a plate, one portion of which has been already exposed so as to yield maximum density, the other portion having received no exposure at all, a very sensitive plate is placed, and if now a suitable exposure be given, it will, on development, be found that the shielded plate has uniform density all over. This proves that  $k$  is the same as regards blue light both for the altered and for the unaltered silver bromide.

The second assumption is that the sensitive film obeys the laws of absorption, as explained at the beginning of this paper. It would prolong this paper very much if we had to furnish here the proof that, as far as the chemically active rays are concerned, and as far as the light *not reflected* is concerned, the law of absorption does hold good. Suffice it to state that, to the more refrangible portion of the spectrum, the sensitive film is as black as Indian ink is to white light.

To recur to our formula, it requires still more alteration to complete it. The density as given by the formula is the maximum density, and expressed as regards the behaviour of white altered silver bromide towards the blue rays of the spectrum. As we know already, we can develop of that maximum density as much as we please, and the change from white to black during development makes the density more or less equal for all rays of the spectrum. We therefore simply multiply the equation by a constant to express this change, and we call this the development constant. The formula then stands—

$$D = \gamma \log_e [O - (O-1) \beta^{k(1-\alpha)} \frac{It}{e}]$$

$k$ ,  $\alpha$ , and  $e$  represent physical and chemical properties of the bromide or silver, which together constitute its sensitiveness to light. We combine them into one single symbol, and write  $i = \frac{e}{k(1-\alpha)}$ , so that we have finally—

$$(2.) \quad D = \gamma \log_e [O - (O-1) \beta^i \frac{It}{e}].$$

This formula represents the density after development as a function of the opacity of the unexposed plate, of the

exposure, and of the symbol  $i$ , which is a measure of the slowness of the silver bromide, and which symbol we shall call the "inertia" of the silver bromide.

To show the approximation of densities calculated by this formula to those obtained in experiments 21 and 22, we append here the calculated and the observed densities. For this purpose the plates used for experiments No. 21 and 22 were investigated for their opacity to the rays of the spectrum from F to H, and this opacity was found to be 332.

*Experiment 21 compared with theory.*

Exposure. C.M.S.	Density Found.	Density Calculated.	Exposure. C.M.S.	Density Found.	Density Calculated.
0.625	.045	.035	80	1.010	.992
1.25	.055	.065	160	1.270	1.272
2.5	.085	.121	320	1.555	1.531
5	.175	.214	640	1.885	1.780
10	.250	.339	1,280	2.088	2.022
20	.460	.520	2,560	2.262	2.218
40	.755	.743	5,120	2.352	2.352

*Experiment 22 compared with theory.*

Exposure. C.M.S.	Density Found.	Density Calculated.	Exposure. C.M.S.	Density Found.	Density Calculated.
1	.060	.092	128	1.875	1.800
2	.160	.172	256	2.200	2.165
4	.340	.302	512	2.535	2.518
8	.590	.482	1,024	2.985	2.860
16	.715	.735	2,048	3.115	3.138
32	.940	1.059	4,096	3.280	3.328
64	1.345	1.405	8,192	3.405	3.405

On examining the "calculated" series of results it will be found that they have exactly the same characteristic properties as those we pointed out as appertaining to the three periods. For the short exposures the calculated densities are nearly proportional to the exposures, whilst from 16 C.M.S. to 1200 C.M.S. the densities increase by nearly equal amounts for every successive double exposure, and differ very little from densities calculated by the simple formula—

$$D = \gamma [\log. It - C].$$

In order that this may be very clearly seen we append another table comparing in column 1 the densities obtained by the correct formula (2), with densities in column 2 calculated by the approximate formula—

$$D = 1.176 [\log. It - 0.579].$$

Exposure, C.M.S.	(1.) Density by Correct Formula.	(2.) Density by Approximation.	Exposure, C.M.S.	(1.) Density by Correct Formula.	(2.) Density by Approximation.
16	.735	.735	256	2.165	2.151
32	1.050	1.089	512	2.518	2.505
64	1.405	1.443	1024	2.860	2.859
128	1.800	1.797	2048	3.138	3.213

We think it necessary to draw attention to this agreement, because the approximate formula is extremely easily applied, whilst the correct formula requires very tedious calculations, and we shall make a very important practical application of such calculations.

Although there is a close general agreement between the experimental results and the numbers calculated by means of the equations, yet in individual cases there are discrepancies. Diagram No. 9 shows the theoretical curves in full lines, the actual observations being indicated by dots. This diagram leaves little doubt that the action of the light on the sensitive film is fairly represented by our equation, and consequently it may be assumed as proved that the action of the light at any moment is proportional to the amount of light absorbed by unaltered silver bromide.

Nevertheless we felt that more experimental proof was wanted to support our equation, which represents the resulting density as a function of the opacity of the unexposed plate to blue light. When it is remembered that the density of the unexposed plate is proportional to the silver bromide spread over its area, it will be perceived that this statement means, in fact, that the density of the image depends upon the amount of silver on the plate in some way, and this is almost a self-evident proposition.

We prepared sensitive plates of different opacities by spreading on equal areas different amounts of silver bromide. These plates were measured to ascertain their opacity to blue light, and the following results obtained:—

Plates No. 1.	Amount of Silver Bromide per 100 Sq. cm.	Opacity to Blue Light.
1	Grms. 0.016	1.738
2	0.031	3.09
3	0.062	10.0
4	0.124	83.0

By means of these opacities four curves were calculated, which are represented in diagram No. 10. To ascertain whether the relative distances between those curves were true, points in each curve belonging to the same exposure (or abscissa) had to be determined in at least two different portions. For this purpose four plates, one of each opacity, were simultaneously exposed, and two different exposures were given of 30 and 240 C.M.S. respectively. The plates were then developed and the ratios of the densities were taken alone for comparison.

The following results were thus obtained:—

Exposure.	Plate I.	Plate II.	Plate III.	Plate IV.
	Density.	Density.	Density.	Density.
30 C.M.S. ....	.065	.095	.260	.272
240 C.M.S. ....	.120	.275	.700	.852
Ratio .....	1.84	2.83	2.69	3.31

The ratios which are obtained for the theoretical densities, calculated by the equation (2), are the following ones:—

—	Plate 1.	Plate 2.	Plate 3.	Plate 4.
Ratio .....	1.70	2.59	2.83	3.22

It will be seen that the theoretical ratios agree as well with the observed ratios as could possibly be expected from so difficult an experiment. In diagram No. 10 the relative distances of the curves, as calculated from the ratios obtained by the experiment, are marked by dots.

Diagram No. 10 is worthy of some remarks. It will be at once perceived that the more thinly the plates are coated the shorter is that portion of the curve which is a straight line. This means that the period of correct representation is very short, and great contrasts cannot be truly rendered by a thinly-coated plate. It will also be found on closer inspection that the centre of the straight portion is in each curve in a different place, and that the thinner the plate the

shorter is the exposure necessary to reach the centre portion. This means that a thinly-coated plate is somewhat faster than a thickly-coated one, though they are made of the same emulsion. A thinly-covered plate, however, appears very much faster than it is in reality. It is ineapable of rendering wide contrasts, and hence the negative always looks flat, and thereby gives to the eye the impression of over-exposure.

We have now learnt the great influence which the opacity of the unexposed plate has on the density of the resultant image, and we must now point out a most important source of error in photographic experiments such as we have described.

If a plate be not perfectly evenly coated, the densities, after development, arising from equal exposures will be different on different parts of that plate. We give here an example of a plate, not a bad one either, on which, in different parts, different exposures were given. The table shows the densities which the same exposure produced on the one half and on the other half of the plate:—

Exposure.	I.	II.	Ratio.
	Density.	Density.	
10	·275	·240	1·14
20	·535	·480	1·12
40	·825	·775	1·06
80	1·185	1·080	1·10

The errors on this plate amount to from 6 to 14 per cent., owing to unequal thickness of the film. It is needless to say that in the dark room, in ruby light, such differences in the thickness of the film cannot be observed. The only remedy for this is to use only very thickly coated plates. We may here say that for our most important experimental work we used slow plates specially prepared for us by Mr. Chapman, of Manchester, every care being taken to secure a thick and even film.

Thickly-coated plates give also very much greater latitude in exposure. The plates used in experiments 21 and 22 would have given good pictures of subjects with contrasts varying from 1:80, though the exposures had varied from 1:2, so that an exposure of 10 seconds, or one of 20, would have resulted in but little difference in the negatives, excepting that the one would have been much slower in printing, because generally denser. Thinly-coated plates, on the other hand, need very accurately-timed exposures.

#### VI.—SPEED OF SENSITIVE PLATES.

We gave two formulæ as the result of our investigations; one of them, the approximate one, is the direct result of our experimental work, the other is the mathematical expression of the idea that a certain definite amount of energy is needed to bring a particle of silver bromide into the condition in which it can afterwards be developed, and that it is only to the light absorbed by unaltered silver bromide that increase of density consequent on increased exposure is due.

Whilst the approximate formula is never strictly true, and can be used only for exposures which fall within the period of correct representation, it is extremely simple, and we are about to describe an important application of it, viz., the determination of the speed of the sensitive plate.

The more correct formula cannot be used for practical applications, owing to its complication, but it serves to indicate the limits within which the approximate formula may safely be used.

In the formula—

$$D = \gamma \cdot \log. (O - (O - 1) \beta^{\frac{1}{i}})$$

we may replace  $(O - 1)$  by the symbol  $O$  when that represents a large number, that is, when the plate is richly coated with silver bromide. If, in addition, we remember

that  $\log_e \beta$  is  $-\frac{1}{\gamma}$ , the equation can be transformed into another, viz.:—

$$D = \gamma \cdot \log. \left( \frac{It}{i} \right)$$

which equation holds good only when the numerical value of  $\frac{It}{i}$  is greater than 1 and less than the opacity  $O$ . It is between these two limits only that this equation gives tolerably correct results. Comparing this last equation with the approximation we gave before, it will be seen that the constant  $C$  of that approximate formula is the logarithm of  $i$ , the symbol measuring those properties of the film which together constitute its sensitiveness, and which we termed the inertia of the plate.

Supposing we had two richly-coated plates, with different inertias,  $i$  and  $i_1$ , and we wished to impress the same density upon them by a given intensity of light  $I$ . They would require different exposures, and the exposures would have to be such that—

$$\frac{It}{i} = \frac{It_1}{i_1}$$

or the times would have to be chosen so that—

$$\frac{t}{i} = \frac{t_1}{i_1}$$

This means that if the values of  $i$  are known for different plates, the exposures required to obtain the same results are also known for those plates, if the exposure is known for any one of them.

The determination of the numerical value of the symbol  $i$  is therefore an important problem.

Since the density of the image is an abstract number, it follows that the ratio  $\frac{It}{i}$  is an abstract number also, and that  $i$  is therefore an exposure. We termed this symbol the inertia, and it really measures that exposure which will suffice to change a particle of silver bromide into the developable condition. But for its practical application it has another meaning. It measures the least exposure which will just mark the beginning of the period of correct representation.

The speed of the plate is the inverse value; the longer the exposure needed to bring the plate just to the beginning of the period of correct representation, the slower is the plate. Therefore we measure the speed of the plate by the value  $\frac{1}{i}$ .

The method we adopt for measuring the value of  $i$  is briefly as follows:—We give to the plate at least two exposures falling within the period of correct representation, and develop. We then measure the densities exclusive of fog. We thus obtain two equations connecting the two densities  $D_1$  &  $D_2$  with the two known exposures  $E_1$  &  $E_2$  viz.:—

$$D_1 = \gamma \cdot \log. \frac{E_1}{i} \text{ and } D_2 = \gamma \cdot \log. \frac{E_2}{i}$$

from which we obtain by elimination—

$$\log. i = \frac{D_2 \log. E_1 - D_1 \log. E_2}{D_2 - D_1}$$

and—

$$\gamma = \frac{\log. E_2 - \log. E_1}{D_2 - D_1}$$

The value of  $i$  is expressed in candlemeter-seconds, and can be found by reference to ordinary tables of logarithms.

We will now describe our practice. For the determination of the inertia, only the central portion of the plate should be used; the margin should be avoided, as it is liable to be irregular in thickness of film. In order to insure at least two exposures falling within the period of correct representation we give to the plate eight different exposures of 2·5, 5, 10, 20, 40, 80, 160, and 320 C.M.S., leaving a portion of the plate unexposed. We develop this plate with ferrous oxalate, and, after properly washing, fix in a perfectly clean bath of thiosulphate. We then wash and dry spontaneously,

or by means of alcohol. The length of time for development is judged by the density of the image. We avoid too great density, but develop sufficiently long to obtain a decided deposit for the lower exposures. When all the densities have been measured we subtract from every one of them the density of the fog strip in order to obtain densities "exclusive of fog."

From this series of densities we may calculate the value of  $i$ . For that purpose we find the differences between the consecutive densities, and we choose from the series those points which give differences most nearly alike. As an example we quote the series of results obtained with the Manchester slow plate of experiment No. 21:—

Exposures ...	2'5"	5"	10"	20"	40"	80"	160"
Densities ....	·085	·175	·250	·460	·755	1·010	1·270
Differences	·09	·075	·210	·295	·255	·260	

We should take the results of exposures from 20 C.M.S. to 160 C.M.S., as those falling within the period of correct exposure. Choosing the exposures 20 and 160 for the calculations, we should obtain, in accordance with the formula given—

$$\log. i = \frac{1.270 \times \log. 20 - 0.460 \times \log. 160}{1.270 - 0.460}$$

or  $\log. i = 0.787$ , and from an ordinary logarithm table we should find  $i = 6.12$  candlemeter-seconds.

In another experiment with a plate of the same make the following results were obtained:—

Exposures .....	10"	26"	40"	80"
Densities .....	·300	·590	·910	1·260
Differences ...		·290	·320	·350

Choosing only the 20" and 80" points, we have—

$$\log. i = \frac{1.260 \times \log. 20 - 0.590 \times \log. 80}{1.260 - 0.590} = 0.771$$

or  $i = 5.90$  candlemeter-seconds.

It will be seen that these values for the inertia of the "Manchester Slow" plate are almost alike. With faster plates it is not so easy to obtain quite such concordant values, but they are always sufficiently accurate for practical purposes, for whether an exposure in practice be four or five seconds it will not appreciably alter the resulting negative, so that in the determination of the inertia an error of 10 per cent. is fortunately not of very great consequence, and in most cases two determinations carefully made will not differ more than 10 per cent.

We prefer, however, to obtain the result by a graphic method, by means of which we avoid all calculations and all references to tables of logarithms. We scratch on an ordinary plate a horizontal scale of inertias similar to the scale of an ordinary slide rule, but we repeat the scale four times instead of twice, as in the case of the slide rule. Diagram No. 11 shows this arrangement. We scratch at points 2.5, 5, 10, 20, 40, 80, 160, and 320 of this scale vertical lines (exposure lines), and divide them each into 20 equal parts, marking the highest as density 2.0, the lowest as 0. Having measured the densities we mark them on the scales of the corresponding exposure lines, and draw a straight line through those points which appear to fall most accurately within such a line. It is better to stretch a white thread across these points, as the portion of the line can thus be more easily determined. Where the thread or the straight line intersects the inertia scale we can at once read off the inertia of the plate.

The solutions of the problem of ascertaining the inertia or its inverse the speed of the plate have hitherto been unsatisfactory, and always depended finally upon the judgment of the comparative visibility of letters or numbers printed upon a sensitive plate.

Our method, by referring the speed to a standard candle as unit will enable different operators to obtain almost identical and definite numerical results. Should at any time a better practical unit of light be found, the method is at once applicable with it also. The fact is, we have based our method on the measured effects produced by a given unit of light, excluding the influence of alterations in development, whilst the present method, by means of Warnerke's sensitometer, depends entirely upon development. We could so alter the composition of the developer as to make a rapid plate give most misleading results.

Such a proceeding is impossible with our method.

There is a theoretical possibility that a plate may be rapid to one developer and slow to another, so as to require different exposures according to the developer used. If silver bromide be reduced to metallic silver, 22,700 units of heat must be supplied to replace the heat of combination. Of this amount of heat the developer in the act of development supplies a portion. Ferrous oxalate, for instance, would probably supply 12,900 units, so that the light need only supply the difference, viz., 9,800 units. But if another developer could supply more than 12,900 units, then the light, clearly, need not supply quite so much, and in that case the plate would be faster to one developer than to another.

We have not paid such close attention to this question yet as to enable us to decide it finally, but as far as our experiments have gone we have found very little difference, if any, between the various developers, and we do not feel justified in assigning to the small differences we have observed any great importance.

If a developer could be found which would render a plate materially faster, that developer would strike a serious blow at the hypothesis that the latent image consists of sub-bromide of silver.

We append a number of interesting diagrams representing our graphic method of determining the inertia of a plate.

*Diagram No. 11* shows the general arrangement we adopt for finding graphically the value of the inertia. An ordinary "slide rule" furnishes the mode of subdividing the scale (the distances of the numbers being proportional to their logarithms). The two curves are the curves of Wratten and Wainwright "ordinary" and "instantaneous" plates. It will be noticed that the "instantaneous" plate shows, within the given exposures, a portion of the period of over-exposure, whilst the "ordinary" shows a portion of the period of "under-exposure." The inertia of the one is 1.4, that of the other 5.5, and in round numbers the one plate is four times as fast as the other.

*Diagram No. 12* shows the results of experiment 15 graphically, for the purpose of showing that variations in the mode of development do not influence the determination of the inertia; the densities of the two modes of development being different, yet the straight lines practically converge to the same point.

*Diagram No. 13.*—This diagram represents another variation in pyro development, viz., in the amount of bromide (experiment 16). It will be again seen that the values of the inertia are almost identical, in spite of a considerable difference in the composition of the developer and the time of development.

*Diagram No. 14* shows four determinations of the inertia of one plate (see experiment 14), two determinations being made with eikonogen and two with hydroquinone. The duration of development being different for each determination, yet the results of all four determinations are practically identical.

*Diagram No. 15* shows that the inertia of a plate can be determined after intensification, but not after reduction. It is, therefore, better to develop too little rather than too much. We clearly must not resort to reduction, but we may intensify if the trial plates have been under-developed. (Experiments 19 and 20.)

*Diagram No. 16* shows the determination of inertia of the Ilford plates, "ordinary," "rapid," and "special rapid" (red label). Their inertias are respectively 2.0, 1.4, and 0.56, and their speeds are relatively as 1 : 1.41 : 3.5. The

"red label" plates are the most rapid plates we have so far investigated, but we found it very difficult to ascertain their true speed in the camera, on account of the difficulty in securing adequate density.

When the inertia of the plate is known, it is possible to time the exposures in the camera so that the densities of the gradations are almost exactly proportional to the logarithms of the light intensities which produced them. By this means negatives can be produced which satisfy very nearly the definition we gave of a theoretically perfect negative. It must be borne in mind, however, that such a negative is not necessarily true to nature. The optical density after development differs from the density of the latent image. If the negative is to be true to nature, a plate must be used which is richly coated, the exposure must be carefully timed, and the development must be carried only so far that the value of the development constant  $\gamma$  is numerically equal to 1. Experiments which we have made indicate that for the production of artistic effects on ordinary silver chloride paper, it is necessary to exaggerate the densities, *i.e.*, to prolong the development until  $\gamma$  is greater than 1, and nearly reaches the value 2. This requires further investigation; suffice it to have pointed out that what Captain Abney terms "photographic untruth" is not necessarily inherent in photography, since the photographer has it in his power to decide the degree of exaggeration.

The exposure to be given in the camera can be found by means of the actinograph,\* when the inertia of the plate is known.

The "actinograph speed" of the plate is found by means of the formula  $S = 34 i$ , where  $S$  is the speed and  $i$  the inertia in candlemeter seconds. We find, for instance, the speed of the Ilford plates from their inertia (as shown on Diagram 16).

	Speed.
Ilford "ordinary" = $\frac{34}{2}$	= 17
Ilford "rapid" = $\frac{34}{1.4}$	= 24
Ilford "special rapid" = $\frac{34}{0.56}$	= 60

This method of referring the sensitiveness of the plate to the candlemeter-second as unit will, we believe, greatly promote progress both in the preparation of the plates and in their application. We flatter ourselves that we have supplied one of the greatest needs of plate makers and photographers in general, by enabling them, for the first time, to ascertain accurately the sensitiveness of different plates, and by means of the actinograph to apply this information in practice.

The above is the main practical result which has accrued from our investigations, but incidentally we have shown the fallacy of many popular views on the subject of development, and the paramount importance of correct exposure.

From a purely scientific point of view, perhaps, the most interesting result of our labour is the elucidation of the numerical relation between the exposure and its effect on the sensitive film, and the simple explanation of these relations, based upon the optical properties of the unexposed sensitive film. It would not have been difficult to extend these considerations so as to include in them the reversing action of the less refrangible rays. This would not, however, have served any practical end at present, and it would have complicated the formula very considerably. We reserve for a future communication this extension of the law which we have discovered.

\* See this Journal, 1890, 370, or the Photographic Societies Reporter for April 30th, 1889.

## A NEW ACTINOMETER.

BY EDWARD GEO. BALLARD, A.R.S.M.

A READY method of measuring the amount of actinic rays proceeding from any landscape or object, has for a long time been a thing much desired by photographers both amateur and professional. Many instruments with this view have been from time to time brought out, some depending upon the darkening of prepared paper to a certain tint, others upon the facility with which a series of numbers can be perceived through screens of certain graduated opacities or darknesses. Mr. Leon Warnerke, some 10 years ago, introduced an instrument in which he employed a plate of luminous calcium sulphide, which was excited by exposure to the object about to be photographed, and thus received a certain degree of luminosity, according to the quality of the light proceeding therefrom. After waiting a certain interval of time, the luminosity was measured by viewing the plate through a series of screens of various graduated degrees of translucency and having numbers or letters upon them; the last number or letter visible to the eye was taken as the indicator of the intensity of the light. So it will be perceived that the intensity or degree of the luminosity exhibited by the plate of luminous sulphide, was, in Warnerke's instrument, taken as the measure of the light which had been acting upon it.

Now it is well known (1) that after the sulphide of calcium is excited by exposure to the light and the source of light is suddenly removed, the bluish phosphorescence emitted rapidly fades, especially when the sulphide is excited to its maximum degree; (2) the amount of light necessary to do this is not so very great; for if two halves of a card covered with luminous sulphide be exposed to light, the one half to a northern sky and the other to bright sunshine, the difference of luminosity exhibited by the two halves of the card is not appreciable when they are examined in the dark.

In the instrument about to be described, advantage is taken of these two facts, and of the fact that luminous calcium sulphide or Balmain's luminous paint is excited by, and emits afterwards, *only* those rays which usually act on the photographic plate.

The rate and manner in which the fading occurs are employed in my actinometer as a means and a standard of comparison for measuring the intensity of the light proceeding from any object, landscape, or sea view. This is arrived at by noting the number of seconds it takes for the luminous sulphide (after having been excited to its maximum) to acquire the same degree of intensity as a portion of the light proceeding from the object, landscape, or sea view in question, and then by referring for the corresponding plate-exposure period to a specially constructed table.

Before explaining how the table of exposures mentioned above is arrived at, it will perhaps be as well to describe the actinometer itself. It consists of a wooden or other opaque tube, coloured dull black inside, open at both ends, and of size and shape at one end convenient for adjustment to the eye. The other end is provided with a second, and similar, but shorter, tube hinged to it, so as to form a sort of lid. This lid is glazed next the tube with a piece of clear, or better, ground glass. Over this is placed a piece of card (or glass) coated with Balmain's luminous paint. A portion of this card is removed (a circular portion is found convenient, for many reasons), and behind this is placed a piece of blue glass wrapped in several layers of tissue paper or other translucent material, and, finally, over all is placed a piece of ordinary glass. The blue glass is capable of cutting off all rays except those corresponding to the colour of the light proceeding from the luminous paint. The use of the tissue paper is to lessen the intensity of the light which passes through the circular opening in the card covered with the luminous paint, to the degree requisite to give correct results with the instrument. This once found is constant for any given make of photographic plate.

To use the instrument, allow the hinged portion A to (Fig. 1.) fall, so that the side containing the card with the luminous paint upon it shall be fully exposed to daylight for 30 seconds. By this time the paint will be excited

Fig. 1.

*a* — Blue glass wrapped in tissue paper.

*b* — Card covered with luminous paint with circular hole in centre.

Fig. 2.

Fig. 3.

*a* — Ground glass.

*b* — Card with luminous paint.

*c* — Tissue paper.

*d* — Blue glass.

to its maximum degree. Place the eye at the end B. Then quickly close the hinged portion A. A blue luminous ground with a dark spot upon it will be seen.

Count the number of seconds it takes for the spot to disappear, *i.e.*, to acquire the same tint as the surrounding luminous sulphide. Then refer to the table, and opposite the number of seconds required for this to take place will be found the correct exposure to be given to the particular make of photographic plate to which the instrument is adjusted. The actinometer itself can easily be adjusted to a plate of any degree of speed by removing or adding to the layers of tissue paper behind the card or glass carrying the luminous paint. Any good table of exposures may be employed for this purpose, or better still that excellent little machine for calculating photographic exposures, called the "actinograph," invented, after much labour and study, by Dr. Ferdinand Hurter and Mr. Driffield, of Widnes.

*The Table of Exposures.*—In order to construct this, it was of course necessary to ascertain how and in what manner the luminous paint faded, in other words to determine the relative intensity of the luminosity of the paint after the lapse of various intervals of time. Three methods were employed for this purpose, and the results obtained by all the methods were found to agree. First, an instrument was made similar in construction to the actinometer already described, except that in addition the hinged portion was provided with a tube, A, inside which another tube, B, was made to slide light-tight, as shown in the drawing, Fig. 2. The inner tube was closed at the end nearest the

tissue paper screen, with the exception of a small circular opening, P, forming a diaphragm which, when presented to a clear northern sky, constituted the standard of light for the experiments. The tube B was graduated in tenths of an inch. In other respects the instrument resembles the actinometer already described, containing in the hinged lid the luminous sulphide with the circular central portion removed, and backed with tissue paper and blue glass.

The luminous surface, having been excited by allowing the hinged portion to fall for 30 seconds and closed again, was observed to acquire the same tint as the central spot at the end of 10 seconds, when the instrument was directed to a clear northern sky, the distance from the tissue paper C to the diaphragm P being noted. The tube B was then drawn out until the diaphragm P was twice the distance from the tissue paper that it was at the first observation. The spot, on repeating the experiment, was found to disappear in 40 seconds. At the next experiment this last distance from the screen was doubled, by drawing out the tube B still further, *i.e.*, to a distance four times what it was in the first experiment. It required 160 seconds now for the spot to vanish.

The next experiments were made with a duplex paraffin lamp. The wicks of the lamp employed were a full inch in width, giving a flame from  $1\frac{1}{2}$  to  $1\frac{3}{4}$  inches wide. At a distance of  $1\frac{1}{4}$  in. from the centre of the lamp between the two wicks a diaphragm was placed  $\frac{1}{2}$  in. in diameter. The light passing through this diaphragm was that employed for the experiments which were conducted with the same

instrument as that already described, with this difference, viz., that the tubes A and B were removed, also the tissue or oiled paper screen c, which latter was placed at the end of the instrument as shown in figure 2 at D. The first observation was taken at a distance of 5 inches from the diaphragm to the tissue paper screen D, when the spot vanished in 10 seconds. The following observations were then made, taking 5 in. as the unit of distance:—

	Intensity.
At a distance .50 from the diaphragm the spot vanished in 2.5 seconds .....	$\frac{1}{4}$
At a distance .75 from the diaphragm the spot vanished in 3.0 seconds .....	$\frac{1}{3}$
At a distance .85 from the diaphragm the spot vanished in 7.0 seconds .....	$\frac{1}{7}$
At a distance 1.00 from the diaphragm the spot vanished in 10.0 seconds .....	1
At a distance 2.00 from the diaphragm the spot vanished in 40.0 seconds .....	$\frac{1}{4}$
At a distance 3.00 from the diaphragm the spot vanished in 90.0 seconds .....	$\frac{1}{9}$
At a distance 4.00 from the diaphragm the spot vanished in 160.0 seconds .....	$\frac{1}{16}$

The intensities of the light emitted by the paint at the end of the various periods of time will be inversely as the square of the distances 1, 2, 3, 4, &c. So by comparing the light passing through the tissue paper and blue glass with the fading luminous paint, its intensity can easily be ascertained; the number of seconds required for the spot to vanish being indicative of the intensity of the light under examination.

In order to check the above, a series of experiments were made with carefully cut diaphragms, placed at a fixed distance from the tissue-paper screen. These diaphragms had the following diameters,  $1, \frac{1}{2}, \frac{1}{4}$ , and the results of the experiments are given below:—

Diameter of Diaphragm.	Intensity of Light admitted.	Seconds for Spot to vanish.			
		Exp. 1.	Exp. 2.	Exp. 3.	Exp. 4.
1	1	10	2.5	7.5	3
$\frac{1}{2}$	$\frac{1}{4}$	40	10	30	12
$\frac{1}{4}$	$\frac{1}{16}$	160	40	120	48

It will be seen that the results are relatively the same.

The following is an example of the application of the foregoing facts. Suppose that upon a certain day, with an F<sub>16</sub>-stop, a plate requires 1 second exposure to obtain a good picture, and that the dark spot of the actinometer vanishes in 10 seconds. Again, suppose that on making an observation of the light on another occasion it is perceived that the spot vanishes in 40 seconds. The exposure needed in the latter case would be four seconds, because the light emitted by the paint at the end of 40 seconds is only  $\frac{1}{4}$  the intensity it was at the end of 10 seconds. This is the same as saying that the light transmitted by the circular opening in the card covered with the luminous paint is only  $\frac{1}{4}$  what it was in the first case: this is precisely what it is desired to measure. When the instrument is thus set to any given plate, the exposure is  $\frac{1}{16}$  of the number of seconds required for the spot to vanish after the luminous surface has been excited. For plates of other degrees of speed special tables can easily be constructed. The instrument when once adjusted to a particular make of plate will indicate the correct exposure under any condition of light and this *with rapidity*, the element of judgment being dispensed with altogether. The difference between the actinometer described and that invented by Warnerke is quite evident. I simply employ the fading sulphide, after being fully excited by exposure to light, as a standard or sliding scale with which to compare a portion of the light proceeding from the object about to be photographed. I have found the instrument extremely useful, and I never have a failure now due to over or under exposure.

MR. IVAN LEVINSTEIN IN THE CHAIR.

### A CONSTANT AIR-BATH.

BY H. GRIMSHAW, F.C.S.

AN air-bath, considered as an apparatus for the quantitative dessication of all kinds of material, should aim at the envelopment of the substance in a moving body of pure air, which is supplied at as near a constant temperature as possible. This is the object, and the more simple and inexpensive the appliance can be made the better. The ordinary form of air-bath, constructed like a cupboard of sheet copper, violates nearly every condition required to attain the objects in view. It is simple enough certainly, but its square form makes it more expensive of construction than a cylindrical one, and its construction makes it absolutely impossible to maintain anything like a constant temperature. In addition to this, the products of combustion from the burner used to heat it corrode the exterior and fill the interior with moisture and carbonic and sulphurous acids.

Adams, in a paper published in the Analyst, XIV., 222, after pointing out the conditions which the ordinary air-bath violates, describes a new form of air-bath which he had constructed, which fulfilled the conditions of being constant to a remarkable degree and entirely prevented the access of the products of combustion to the interior of the bath. On careful consideration of the construction of this bath, which is illustrated by a diagram, I considered that a much simpler, cheaper, and practically as efficient an air-bath might be made, and the result of my attempt in this direction having been, so far as I can judge, very satisfactory, I considered that it would be of interest to the Society.

The construction of the bath will, I think, be seen at a glance from the diagram appended, which is one-eighth the real size. It consists of four parts—(1), the body; (2), the vessel forming the air envelope or casing; (3), the base all of which are cylindrical; (4), the lid or cover. The body is made of cast iron or brass, and is merely a cylinder 11½ in. in diameter externally and 8 in. deep, closed at the bottom, and of a uniform thickness of ½ in. The object in making this so thick is to provide a mass of metal which will distribute and to a large extent control the heat. This part might be made of sheet copper or even stout sheet iron, but would not be so effective. Also the body and the base might be cast in one piece, but this would add unnecessary weight.

The base is made of stout sheet iron or sheet copper, and is, in the model I have made and used 11½ in. in diameter and 7 in. deep. It is cylindrical, and closed at the top. It is

provided at the bottom with semicircular apertures for the admission of air to the Bunsen lamp, and close to the top are four short chimneys of sheet iron at least 1 in. in diameter turned upwards at a right angle. The object of these is to carry away the products of combustion and deliver them at a level above that of the intake of air to the drying chamber, thus avoiding the presence of these gases in the interior of the air-bath. Attached to the top of this part of the apparatus is a kind of baffle-plate of  $\frac{1}{2}$ -in. iron to receive the flame of

the Bunsen instead of allowing it to play directly upon the top of the base cylinder, by which means radiation of heat from the bottom of the bath is lessened, and the sheet metal of the base is not burned away. I need scarcely say that all the joints of this heat chamber or base should be made tight without the use of solder, which would be melted out. A rose burner is better than the ordinary Bunsen as the source of heat. In the next bath which I make I intend to make the base of a slightly greater diameter, so that in packing the air-bath for transit or storage the other portions may be placed inside it to save room.

The third portion of the bath, which I will call the air-case, is merely a double cylinder of sheet iron or copper open top and bottom, but with the space between the two cylinders closed at the top and open at the bottom, so as to slide over the body of the bath, leaving an air space of about  $\frac{1}{4}$  of an inch on each side of the body, the thick metal of which imparts its heat to the air as it travels up the outside and down the inside. The air-case is of course cylindrical, the internal cylinder being  $10\frac{1}{2}$  in. in diameter, and the outer cylinder about 1 in. wider, whilst the height of each is about  $8\frac{1}{4}$  in. I propose to try the effect of adding still another enveloping cylinder externally to this part of the bath, through which the heated air from the base will circulate, which will give an economy of heat and possibly still greater regularity. A series of "notches" taken out of the bottom edge of the interior cylinder admit the hot air uniformly all round the cover of the circumference of the air-bath, and this is caused to rise very uniformly into the whole of the chamber by means of a finely perforated plate, shown by the dotted line.

The fourth part of the air-bath is the cover which is made double to prevent radiation of heat, and has a chimney 2 ins. in diameter and about 2 ins. or 3 ins. high. The chimney may have a circular damper fixed on a swivel or a series of perforated caps to regulate the draft of air through the drying chamber. Through the lid there is a 1-in. aperture for a cork carrying the thermometer. Another similar aperture may be made to carry a maximum thermometer to indicate whether, between the intervals of reading, the heat of the bath has been any time too high.

The diagram shows a stand inside the bath of about the right height to bring the vessels containing the substance into the most constant zone of heat. The outside of the bath may be of course japanned or coloured as desired.

The air-bath of Mr. Adams, previously alluded to, contains a closed cylindrical chamber encircling the air chamber, the expansion of the air in which, by the usual contrivance of a mercury lute cuts off the supply of gas more or less according to the temperature. This introduces an expensive complication into the construction of the bath, which, I fear, will always be liable to go wrong and render the addition useless. If necessary for very refined work of course an expansion apparatus could be added to this air-bath, but I should prefer it to be entirely separate in construction from the bath itself, and its connexion with the gas supply pipe to be through an aperture in the cover, such as the one for the thermometer.

In practice I have found that with the Manchester gas supply there is no real need for a regulator, if the gas supply is looked to in the morning and evening when the extra pressure is put off and on the gas mains, the bath keeps within about one degree as a rule.

In working further with the air-bath I shall obtain a record of its performance which, if of sufficient interest, I will take the liberty of placing before the Society.

#### NOTE ON THE DECOMPOSITION BY HEAT OF THE CHLORIDES OF MAGNESIUM AND CALCIUM.

BY H. GRIMSHAW, F.C.S.

It is not a new observation that when the chlorides of calcium and magnesium are heated in contact with air, a portion of this chlorine is given off.

In view of the very large quantities of both these substances used in the sizing and finishing of cotton and other goods, it is evident that it is of considerable interest and importance to define at what temperature, at how low a temperature in fact, and to what extent the decomposition of these salts proceeds, because if the chlorine is liberated at temperatures to which it is at all likely that the fabrics containing them may be subjected, under the ordinary conditions of their use and manufacture, then the chlorine or resulting hydrochloric acid will be certain to cause more or less deterioration of the fabrics.

We know that at a red heat the chloride of calcium becomes alkaline to litmus, and that at temperatures considerably lower than this the chloride of magnesium parts with an appreciable amount of its chlorine. Recently several cases of deterioration of the strength of cotton fabrics have been traced to the action of chloride of magnesium, and we may take it, I think, as an undoubted fact that this "tendering" of the cotton fibre in such fabrics is due to the action of the hydrochloric acid formed by the decomposition of the chloride.

I am making an attempt to define with accuracy the lowest limit of temperature at which the decomposition of the chlorides of calcium and magnesium, and incidentally the chloride of zinc, takes place, the extent of the decomposition, and the influence of time, and the presence of moisture, have upon this, and I am able to give some figures which though only of a preliminary nature are of interest on some of these points.

The method I have adopted in the experiments is as follows:—

I prepare a solution in distilled water of the chlorides of calcium and magnesium respectively, of which I take so many cubic centimetres for each trial, so avoiding a good deal of time and trouble in weighing. I also prepare a decinormal solution of silver nitrate, which serves to estimate, by the usual volumetric method the chlorine either before or after heating.

(1.) Twenty-five cc. of the calcium chloride solution took  $18.3$  cc. of the decinormal silver nitrate, and  $25$  cc. of the magnesium chloride solution took  $16$  cc. of the silver nitrate.

(2.) Twenty-five cc. of the calcium chloride and magnesium chloride solutions respectively were evaporated to

dryness on the water-bath, and then subjected for five hours to a temperature of  $150^{\circ}\text{C}$ . in the air-bath which I describe in another paper. The residue was in each case taken up with water, and after filtration, titrated with the standard silver solution. The calcium chloride took  $18.3\text{ cc.}$  as before, and the magnesium chloride only  $9.7\text{ cc.}$ , showing a very considerable loss of chlorine.

(3.) Twenty-five cc. of the calcium and magnesium chlorides solutions were evaporated to dryness as before and subjected to a temperature of  $165^{\circ}\text{C}$ . for a period of two hours. On titration as before, the calcium chloride residue took again  $18.3\text{ cc.}$  of standard silver, whilst the magnesium chloride residue took  $10.7\text{ cc.}$  The temperature was higher, and the time of exposure less than in experiment No. 2.

(4.) Twenty-five cc. of the magnesium chloride was taken, evaporated, and heated as before, but with a temperature of  $117^{\circ}\text{C}$ . and an exposure of three hours. On solution and titration as before,  $15.2\text{ cc.}$  of the standard silver were consumed.

These few preliminary experiments would appear to establish the fact, that at any temperatures which can possibly prevail in the manufacture or use of goods containing the calcium chloride, this salt is perfectly stable, and no fear of deleterious action need be entertained, whilst the reverse is the case with the magnesium chloride. The figures for the latter show that this salt is decomposed comparatively readily at a low temperature; a temperature of  $117^{\circ}\text{C}$ . is one which in some operations the fabric may easily attain, and it would appear likely that an even lower temperature may effect this.

I hope shortly to complete an extensive series of experiments to define these points more definitely still with regard to the magnesium and calcium, and also directed to show whether the chloride of zinc is more or less stable than the chloride of calcium, as it is a salt which is also very largely used in the same connexion.

I should like here to acknowledge the co-operation of my laboratory assistant, Mr. W. Wilson, in the carrying out of the method of experimenting.

Chrystal; Committee: W. J. A. Donald, C. A. Fawcett, J. Falconer King, T. P. Miller, J. Pattison, and R. R. Tatlock.*

### SESSION 1890.

June 3rd (Glasgow):—

Dr. J. Clark and Mr. McGhie. "A new Cobalt Mineral."

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

*Meeting held 6th May 1890, in the Rooms of the Philosophical Society, Queen Street, Edinburgh.*

MR. G. BEILBY IN THE CHAIR.

## AN ACCOUNT OF THE MANUFACTURE OF PHOSPHORUS.—PART II.

BY J. B. READMAN, DSC., F.R.S.E., F.C.S., EDINBURGH.

THE first part of this paper on the manufacture of phosphorus described in general terms the present method of preparing that element on the industrial scale. The process so described is open to many objections, and is one which results in much loss of material.

In the first place it involves, for its economical accomplishment, what may be considered independent manufactures which require to be conducted conjointly with it, each one involving its distinct plant and apparatus. For example, to supply the acid necessary for the decomposition of the phosphate of lime, vitriol chambers, with their accessories, require to be erected.

An extensive breaking and grinding plant for the raw material must also be available, and further, in order to provide retorts, which ought certainly to be made on the spot, commodious premises for moulding, drying, storing, and ultimately firing them, have to be conveniently arranged. Besides all this, the extensive filtering service required, the disposal of the waste sludge (hydrated sulphate of lime), the numerous store and stock tanks for acid liquors of different strengths. The series of lead evaporating and drying pans, and the distillation at a high temperature of the desiccated mixture of phosphoric acid and carbon in what are practically small pipes or crucibles, each one yielding only a pound or two of phosphorus involve a large plant, and the manipulation of much material contrasted with the small amount, comparatively, of phosphorus obtainable.

Moreover, the process I described is wasteful on account of the loss of material entailed at its various stages; even with the most careful washing of the sulphate of lime in the filters it is impracticable to remove all the free phosphoric acid from it, for to effect this completely the effluent washings would be so weak and so charged with sulphate of lime in solution as to render their introduction into the process objectionable rather than helpful.

Loss of phosphoric acid is also incurred—as was pointed out—by the presence of bases, such as iron and alumina in the concentrated acid liquor and the ultimate re-formation of insoluble phosphates; but the most serious source of loss, and that of phosphorus in its free condition, occurs in the distillation of the desiccated mixture of acid and carbon in clay retorts. Whatever amount of care is bestowed on the manufacture of retorts, frequent cracking and breaking, or pinholes, accompanied by escape of phosphorus, are inevitable at the high temperature required for the operation. This is abundantly proved in the case of zinc, the distillation of which bears a strong analogy to that of phosphorus, but in the former case the retorts are subject to no internal pressure whatsoever, whereas the phosphorus retorts have a slight water seal, and this undoubtedly is a factor when accounting for the loss in distilling in fireclay vessels so inflammable a substance as phosphorus.

Furthermore, the wear and tear throughout the process is excessive, and the cost for upkeep of plant and the renewal of retorts and furnaces very heavy.

With these facts before me I initiated some years ago a series of experiments to ascertain if a more simple and cheaper process of producing phosphorus could be found, dispensing with the use of sulphuric acid and also with the employment of retorts.

For the last three years or more, as circumstances permitted, I have carried out many experiments in this direction, involving upwards of 250 separate fusions, many of them requiring a continuation of the heat for several hours' duration.

The materials used in the first instance were phosphate of lime, silica in the form of sand, and carbon in various conditions, and the apparatus consisted of Morgan's plumbago crucibles "Salamander" size No. 8, and a Sefström's blast furnace.

The object of the preliminary experiments was to ascertain first if silica at high temperatures, and in presence of carbon is capable of expelling, practically, all the phosphorus contained in an intimate mixture of these two substances along with phosphate of lime; and, second, if the silica after, or during, the expulsion of the phosphorus, formed with the lime of the phosphate of lime a fusible slag which would remain in a liquid condition so as to admit of its ready withdrawal.

Specimens, showing the results of some of the experiments, are lying on the table, and will be severally referred to.

In the first of the series of experiments the following proportions were employed, viz. :—

	Parts.
Charleston phosphate of lime .....	100
Sand .....	40
Coal .....	15

These ingredients—all in a fine state of division—were intimately mixed, then slightly damped to promote cohesion, and finally introduced into a plumbago crucible previously raised to a full red heat in the Sefström's blast furnace. The crucible remained in the furnace for one hour and 15 minutes, and during part of that time was subject to a bright red heat approaching whiteness; it was then removed, allowed to cool, and examined.

It was found that fusion had taken place to a small extent round the sides of the crucible, but that the interior was practically unchanged. The resulting slag (part of which is contained in the specimen bottle), was so unsatisfactory that no analysis was made of it—very little phosphorus appeared to be evolved.

The next trial was precisely the same as the one just described, with the one exception that more sand was used in the mixture. The result was a rather increased fusion with partial decomposition of the phosphate of lime, but still incomplete and unsatisfactory.

Having failed in these two experiments to effect complete fusion and decomposition of the mineral phosphate of lime, it was resolved in the next experiment to substitute for the latter basic slag from the Bessemer steel process. The proportions used were—

	Parts.
Basic slag (ground) .....	100
Sand .....	67
Coal (ground) .....	10

These ingredients were carefully mixed and treated as before described.

The mixture fused completely in 15 minutes, and on pouring out the contents of the crucible and cooling, the slag was found to be vitreous in character and of a dark greenish-brown colour (see specimen). Besides the slag a large metallic, very brittle, button was obtained, which on examination was found to consist of phosphide of iron possessing the following composition—

Iron .....	71.63
Phosphorus .....	23.23
Silicon, manganese, &c. ....	5.00
	100.00

This corresponds approximately to the formula  $\text{Fe}_2\text{P}$ .

It was found in this experiment, and the result was amply confirmed in others which followed, that when basic slag is heated with the proper proportion of silica and carbon—though perfect fusion may result—a very small proportion of the phosphorus is expelled from the crucible, the great affinity that iron possesses for phosphorus preventing the expulsion of the latter, which if liberated at all at once combines with the large quantity of iron present in these basic slags, with the formation of phosphide of that metal while the lime, manganese, magnesia, &c., combine with silica to form a complex silicate, which, as is well known, is fusible at temperatures that silicate of lime withstands.

(I shall have occasion to refer once again to some further experiments with basic slag, the only phosphorus-bearing

material present in the mixture, during which a very much increased temperature was employed.)

Failing to expel phosphorus at the temperature employed from either native phosphate of lime or from basic slag, experiments were next made using a mixture of the two. The first of the series was performed with an intimate mixture of the following substances—

	Parts.
Charleston phosphate of lime (11.86 per cent.) ..	100
Basic slag .....	50
Sand .....	75
Coal .....	41
	270

This mixture, after one hour in the crucible, produced a very fluid slag (see specimen), and during the operation a large quantity of phosphorus was disengaged, which blazed at the mouth of the crucible with characteristic brightness. The contents of the crucible after the operation weighed 167 parts, and the clean slag on analysis was found to contain 1.37 per cent. of phosphorus only. Proving that a large quantity of phosphorus had been removed during the fusion, shots of phosphate of iron from the basic slag were found dispersed through the residue.

The next experiment was made with the same materials, using slightly different proportions, viz. :—

	Parts.
Charleston phosphate of lime (11.86 per cent. P.) ..	100
Basic slag .....	33
Sand .....	75
Coal .....	33
	241

This mixture fused well, and the resulting residue weighing 175 parts had the following composition :—

	Per Cent.
Phosphorus .....	2.23
Silica .....	55.60
Lime .....	27.37
Undetermined .....	14.80
	100.00

In this case the total phosphorus existing in the original mixture amounted to 1036.75 grains—the phosphorus remaining in the slag and buttons 292.3 grains—the difference, 744.72, being phosphorus expelled. This is equivalent to 71.8 per cent. of the whole phosphorus contained in the mixture.

The escape of phosphorus as before was sufficiently evidenced by the bright flame of that element proceeding from the crucible during the decomposition. Seven supplementary experiments were next made, varying the proportions of the ingredients slightly in each case.

The next material used was pure bone ash, intimately mixed with basic slag, sand, and coal. The proportions were—

	Parts.
Bone ash (17.66 per cent. P.) .....	100
Basic slag .....	33
Sand .....	80
Coal .....	33
	246

This mixture also fused well and yielded a residue which weighed 176 parts and contained—

	Per Cent.
Phosphorus .....	2.82
Silica .....	49.12
Lime .....	34.13
Undetermined .....	13.93
	100.00

In this mixture, inclusive of the basic slag, there were 1324.5 grains of phosphorus, and in the residue 372.8 grains, showing that 951.7 grains had been expelled or 71.1 per cent. of the whole.

This slag was extremely fluid and highly vitreous (see specimen). Having now proved the possibility of expelling phosphorus from the ordinary phosphates of lime met with

in commerce, the next endeavour was to condense it, and with this object a charge was made up as follows:—

	Parts.
Charleston phosphate of lime.....	100
Basic slag.....	33
Sand.....	71
Coke.....	27
	<u>231</u>

The ingredients were carefully ground and mixed as before and were then introduced into a tabulated plumbago retort made specially for these experiments by the Morgan Crucible Company, Battersea; the retort was placed in the Sefstrom furnace and was then connected to a series of condensing vessels. The heat was carefully and gradually raised until a high temperature was attained. Phosphorus soon began to distil over, and when the distillation appeared to be at an end, the retort was disconnected and the condensed phosphorus collected. The result gave—

Total phosphorus in charge.....	968.25 grains.
Phosphorus condensed.....	534.00
Do. escaped uncondensed.....	264.25
Do. left in residue.....	170.00
	<u>968.25 grains.</u>

This is equivalent to a yield of 55.1 per cent. of the whole phosphorus present in the mixture, and includes 104.2 grains of phosphorus (=10.7 per cent. of total present) contained in basic slag, which, as we have seen, yields practically no free phosphorus when treated in this way.

The next endeavour was to dispense with the employment of basic slag and to imitate, as far as possible, the very fluid slags obtained in the reduction of iron ores in the blast furnaces.

A typical slag from one of the furnaces in the West of Scotland was obtained and its composition determined. The following is the analysis:—

	Per Cent.
Silica.....	38.60
Alumina.....	12.85
Lime.....	32.54
Oxide of manganese.....	4.98
Oxide of iron.....	.64
Magnesia.....	6.49
Sulphide of calcium.....	3.58
Phosphoric acid.....	Trace.
	<u>99.68</u>

This slag, when introduced into the crucible, fused readily in 10 minutes and remained fluid for three minutes after pouring into the small ladle.

A mixture was now made with—

	Parts.
Charleston phosphate of lime.....	100
China clay.....	50
Charcoal.....	17

This mixture fused well and yielded a slag (see specimen) which contained 1.86 per cent. of phosphorus.

Another trial was made with the addition of 20 parts of sand. This mixture also fused readily and gave a slag of the following analysis. (See specimen.)

	Per Cent.
Phosphorus.....	1.74
Silica.....	40.92
Lime.....	37.70
Alumina.....	17.08
Undetermined.....	2.56
	<u>100.00</u>

On the table are slags from six additional experiments with different proportions of these ingredients.

Further trials were next made, using in addition black oxide of manganese. The slag resulting (see specimen) has the characteristic manganese colour, and its chemical composition closely approximates to the iron slag before referred to. The phosphorus remaining in this case amounts to only 0.86 per cent.

### Analysis of Slag.

	Per Cent.
Phosphorus.....	0.86
Silica.....	42.44
Lime.....	32.41
Alumina.....	15.61
Manganese, &c.....	8.69
	<u>100.00</u>

Specimens of the results of further experiments are before you.

Having succeeded both in obtaining a readily fusible slag and also in expelling phosphorus from these mixtures, repeated attempts were again made to obtain phosphorus from basic slag as being the cheapest source of phosphorus at present in the market. A mixture was made of—

	Parts.
Basic slag.....	100
Fire-clay.....	50
Charcoal.....	50

A high temperature was used and the mixture became perfectly fluid in the short space of 10 minutes, but as before, it was found that practically all the phosphorus combined with the iron present in the slag, forming the brittle phosphide (see specimen) described previously.

Arrangements were now made to employ a higher temperature in future experiments; this was accomplished by increasing the pressure of the air blast and by the employment of a superior quality of coke in the furnace. The object of the increased temperature was to endeavour to effect the decomposition of phosphate of lime by silica and carbon alone—as in the first experiment of all—without the use of extraneous fluxes. A trial was made with an intimate mixture containing—

	Parts.
Charleston phosphate.....	100
Sand.....	50
Coke.....	20

This was introduced into a plumbago crucible previously heated to whiteness in the Sefstrom furnace, and this temperature was maintained during the experiment.

The result was a very fluid slate-coloured slag of the following composition:—

Phosphorus.....	1.35
Silica.....	49.88
Lime.....	33.04
Undetermined.....	15.73
	<u>100.00</u>

Similar results were obtained using other mineral phosphates, such as "Canadian," "Somme," "Spanish," thus proving that if temperature employed be sufficiently high fluxes are not required to form fusible slags with these substances. Having established this point the next and principal one was to ascertain the yield of phosphorus from these simple mixtures, and for this purpose a charge weighing about 5 lb. was prepared and distilled in a plumbago retort, precisely similar to the one on the table. The details of this experiment are as under:—

WEIGHT OF ORIGINAL MIXTURE 34,000 GRAINS, CONTAINING 2,372 GRAINS P.

	Grains P.
Weight of slag 22,760 grains, containing 1.3 per cent. P, equal to.....	295.8
Weight of phosphide of iron 320 grains, containing 23.2 per cent. P, equal to.....	74.2
Total P left in residues.....	369.0
Yield of crude phosphorus obtained in condensers.....	1,730.0
Phosphorus which escaped condensation, by difference.....	273.0
Total P in original mixture.....	<u>2,372.0</u>

(This is a yield of 72.2 per cent. of crude phosphorus.)

Upwards of 20 confirmatory experiments were made, which fully proved the correctness of the figures here tabulated.

Having now given sufficient evidence of the possibility of obtaining phosphorus by the action of silica and carbon on mineral phosphates forming as a by-product a fusible slag,

my next endeavour was to devise an apparatus to carry out the reaction, as both from the nature of the slag and the very high temperature required retorts were not capable of being employed for any length of time. Patents had been taken out by several investigators (Aubertin, Brison, and Serve), all Frenchmen, claiming among other things the employment of the blast furnace for the manufacture of phosphorus. These patents have all lapsed, and do not appear to have ever been prosecuted on a technical scale for any length of time. The specifications lie on the table, and may be of interest. The following is a short summary of each. Aubertin and Boblique, of Paris, took out in 1867 provisional protection for "A new or improved process for the direct production of phosphorus for industrial purposes," in which phosphate of lime is mixed with 200 per cent. of silica and 25 per cent. of charcoal or coke dust, and introduced in a pulverised state in a closed vessel, and heated to a temperature between orange red and white heat, the reaction (it is added) taking place without it being necessary to melt the mixture?

In 1868, Brisson, of Chalons-sur-Saône, took out a complete patent for "Improvements in the manufacture of phosphorus and amorphous phosphorus, and in furnaces and apparatus employed for that purpose." He makes two claims: first, the manufacture of phosphorus by means of a blast furnace combined with a blowing engine; second, the direct admixture in the blast furnace of the fuel with the materials for producing the phosphorus.

In 1870, Aubertin again appears, having taken out provisional protection only, for "Improvements in the manufacture of phosphorus," in which he employs the same materials as before, adopting what he describes as the "calcination" or the "fusion" process. In the former case he uses furnaces or retorts and excess of silica, to prevent fusion, and in the latter he adds just sufficient silica to form a fusible slag, and employs for the reaction "that description of blast furnace known as 'Fluss-Ofen,' employed in Styria and Carinthia."

Lastly, in 1879, Serve, of Givors, France, took out a complete patent for "Improvements in the manufacture of phosphorus," in which the following claims are made: First, the preparation in the form of blocks or bricks of an intimate mixture in suitable proportions of phosphates of lime, baryta, or other earthy phosphates, and of silica or other silicious body, bound or held together by a carburetted body, such as tar, pitch, or coal. Second, The extraction of the phosphorus from above by the employment of ordinary retorts or other suitable apparatus, but by preference a blast furnace similar to those used for smelting iron. Third, The construction of apparatus shown in the drawing, consisting of a furnace and condenser connected therewith.

The other patents that have been taken out in this country in connexion with the manufacture of phosphorus will be fully entered upon in the concluding paper on this subject.

The blast furnace as a substitute for retorts seemed an apparatus likely to be successful, especially in view of the fusible mixtures obtainable; and with the object of proving it I erected several successive eupola furnaces in the neighbourhood of Edinburgh at a cost of over 1,200*l*. The first one was soon demonstrated to be too small, and a water-jacketed eupola of 18 in. internal diameter was substituted. This was used for some time, and was then modified, and finally a brick-lined furnace, about 3 ft. 6 in. internal diameter, was erected. The finely-ground and incorporated ingredients were made into bricks or balls by various binding agents, and presented the appearance of the specimens before you. The blast was obtained by a Roots' pressure blower, and both the hot and the cold blast were employed.

I have tracings of these furnaces and blowers here, but the description of the experiments will form part of the final paper, as perhaps I have entered already too much into the details of the preliminary work.

## BLASTING-GELATIN, AND SOME OTHER EXPLOSIVE MIXTURES.

BY GEORGE MCROBERTS, F.R.S.E., F.C.S., F.L.C.

IN a former paper I dealt with the method of manufacturing blasting-gelatin, but in this paper I intend to speak more of the material itself than of the way of preparing it. Blasting-gelatin, properly so called, consists of from 92 per cent. to 93 per cent. of nitro-glycerin and 7 per cent. or 8 per cent. of nitro-cotton. The kind of nitro-cotton used is not the ordinary gun-cotton, or tri-nitro cellulose, but is a mixture of mono- and bi-nitro-cellulose. The latter is soluble in a mixture of alcohol and ether, and forms the well-known colloid; and it is also soluble in nitro-glycerin, especially when the latter is heated. With nitro-glycerin it forms a jelly thick or thin according to the proportion of nitro-cotton used. Blasting-gelatin, consisting of 93 per cent. of nitro-glycerin and 7 per cent. of nitro-cotton, is the strongest form of it, and so far as experience has yet shown, it is the most powerful explosive in existence. It has a specific gravity of 1.55; is of a yellowish colour, semi-transparent, and is elastic to the touch. It is insoluble in water, in which it can remain any length of time without injury to its explosive properties; and, when exploded, it is wholly resolved into gas at a high temperature; and the ballistic result is found by the mortar to be about 50 per cent. greater than that of the best dynamite. For some purposes, this form of blasting-gelatin is the best. It can be used under water with great facility. There are, however, some kinds of blasting for which milder forms of gelatin are more suitable; and, accordingly, the manufacturers have endeavoured to supply the wants of customers by modifying in various ways the energy of the explosive. This is done by mixing with thin gelatin, consisting of 95 per cent. or thereby of nitro-glycerin and 5 per cent. of nitro-cotton, a mixture of wood-meal and nitrate of potash, or of charcoal and nitrate of potash; in fact, by mixing with the gelatin two of the ingredients of ordinary gunpowder. Various names have been given to these mixtures, but whatever name may be given to the mixture it is in every case less powerful in blasting than the original gelatin. One good mixture consists of 80 per cent. of thin gelatin (95 per cent. of nitro-glycerin and 5 per cent. of nitro-cotton) and 20 per cent. of a mixture of wood-meal and nitrate of potash. The latter mixture consists of 16 parts of nitrate of potash and four parts of wood-meal or charcoal. The usual name given to this form of gelatin is gelatin-dynamite. Another useful mixture consists of 60 per cent. of thin gelatin (96 per cent. of nitro-glycerin and 4 per cent. of nitro-cotton) and 40 per cent. of the mixture of wood-meal and nitrate of potash (32 parts nitrate of potash and 8 parts of wood-meal or charcoal). The mixture with wood-meal and nitrate of potash, as I have explained above, lessens the energy of the explosive, and modifies its effects in blasting, so that the rock is broken into larger fragments than is the case when pure gelatin is used. At the same time, wood-meal and nitrate of potash, being cheaper than nitro-glycerin, render the cartridges less costly to the miner.

A little consideration will show that it would be comparatively easy to make many varieties of blasting-gelatin by mixtures, more or less effective, of thin gelatin, with ingredients either explosive or non-explosive; and, in fact, many attempts have been made by inventors at home and abroad to improve on blasting-gelatin by mixing it.

In making mixtures of blasting gelatin or nitro-glycerin, or nitro-cotton, with other ingredients, great attention must be paid to the chemical constituents of the mixtures. Blasting gelatin is, without doubt, the most perfect of explosives in this sense—that the carbon, hydrogen, and oxygen present are just in the exact proportions required to form carbonic acid and water, and thus develop, at the moment of explosion, the maximum of heat and expansion. In mixing this form of explosive, therefore, with other ingredients, the greatest care must be taken that the latter contain within themselves enough of oxygen for the carbon present to produce perfect combustion, otherwise there will be a loss of power—neither the mixture nor the gelatin producing good effect.

A great many inventors are in the field with smokeless powder. Up till now there are several hundred patents in connexion with this matter, but hitherto the success of the inventors has not been great. No powder that has yet been tried is absolutely smokeless; but what is meant generally, by a smokeless powder, is one in which the oxygen of the explosive combines perfectly with the carbon, to form carbonic acid, and with the hydrogen, to form water. If the ingredients are mixed, in chemically rational proportions, then the amount of oxygen present will just be such that the whole of the carbon and the hydrogen, when the explosion takes place, will combine with it, and form carbonic anhydride ( $\text{CO}_2$ ) and water ( $\text{H}_2\text{O}$ ). There will then be no smoke—for what we usually understand by smoke is the presence of small particles of uncombined carbon in the air. A smokeless powder that fulfils those conditions possesses great energy, seeing that the heat developed at the instant of explosion is the highest possible; and the gases formed, therefore, have the maximum of expansion. One of the best smokeless powders consists of a modification of blasting-gelatin, made by mixing it either with the ordinary gun-cotton, or with collodion cotton, to such an extent that the finished substance is dry and elastic.

Nobel's Patent Smokeless Powder, which he calls Balistite, is formed in that way. It usually consists of about 50 per cent. of nitro-glycerin and 50 per cent. of nitro-cotton. This substance is not powder in the ordinary sense—that is, a substance in a state of fine division. It is in the form of cakes, or squares, or cubes, or cords. It presents the appearance of elastic rubber, or vulcanite when rolled into a sheet. When set fire to it burns slowly with a yellow flame. When kindled in a confined space the gas developed does not escape, until it attains a certain pressure; and as it does this much more slowly than ordinary gunpowder, it can be used in guns with much effect, and without danger.

Another variety of smokeless powder, patented by Sir Frederick Abel and Professor Dewar, consists of nitro-glycerin and ordinary gun-cotton or nitro-cotton, with or without other ingredients—the combination of which is assisted by the use of acetone or other solvents. This material can be made in any form, but it is specially good in the form of thin cords or threads, which can be rolled up into cartridges of any size and any form, for small arms or for cannon. This smokeless powder has been adopted by Her Majesty's Government for use in the British Army and Navy, and I have no doubt it will, by-and-bye, become well known.

In making a smokeless powder, consisting of about 50 per cent. of nitro-glycerin, and 50 per cent. of nitro-cotton, the combination of the two explosives is assisted by the use of solvents. Various solvents, such as ether, acetone, &c. may be used, and the sensitiveness of the explosive mixture modified to any extent by adding a small portion of camphor to it—say, 2 to 5 per cent.; but in any case, the combination cannot be satisfactorily effected without the aid of heat. The heat may be obtained with safety from hot water.

As in the case of Nobel's patent for blasting gelatin, the inventor describes no machinery in the Balistite patent by which that substance can be made, but it is evident at a glance that to manufacture the material on a commercial scale, it will be impossible to avoid using machinery; and the manufacturer who attempts to work Nobel's patent balistite will have to devise machinery and plant for the purpose. That itself will demand considerable inventive talent. Machines to make this substance must be arranged to guard against the application of too high a temperature, and to avoid undue friction or pressure of the explosive—otherwise dangerous accidents may result.

For the manufacture of Cordite, which is the name given to the smokeless powder patented by Sir Frederick Abel and Professor Dewar, excellent machinery has been, or is being made at Woolwich Arsenal, which appears to answer all the conditions required for turning out readily and rapidly a supply of explosive cords which, from that form, may be made into cartridges of any shape and size.

From trials made on guns at Woolwich, it appears that this new smokeless powder, Cordite, gives, in rifled muskets, an initial velocity of about 2,000 ft. per second, while the

pressure within the barrel of the gun is less than that produced by the ordinary black powder. If these results can be maintained, there is a great future for this smokeless powder, and there can be little doubt that it will, by-and-bye, almost entirely supersede black powder for guns, both for the purposes of war and sport. It has the great advantage over ordinary gunpowder of not being spoiled by water, and that is a circumstance of much importance, because armies in the field using black powder for cartridges have to take great care to keep their ammunition dry. Such precaution will be unnecessary in the case of the new smokeless powder, which burns as readily under water as in the open air.

The following table of mortar trials is given to show the ballistic effect of various explosive mixtures. The mortar in which the trials have been made is suspended by arms 10 ft. in length, from a rigid framework. It is free to swing from the effect of the shot, and the length of its flight is registered automatically by an arrangement fixed to the mortar itself, so that in every case the angle through which it swings from the shot is accurately recorded. The weight of the mortar is known, and when the angle through which it swings is ascertained, sufficient data have been obtained to calculate the work done by the shot. The weight of the explosive, in every case, is 10 grms., and the work done is reduced to foot pounds. The 10 grm. charge of explosive is always ignited by a fuse and detonator. The latter contains from 7 to 8 grains of a mixture of chlorate of potash and fulminate of mercury.

#### ENERGY OF EXPLOSIVES.

The mortar is by no means a scientifically accurate instrument, and does not measure or record the total work done by the explosive; but in that respect the trials are alike for every explosive, and the comparative results may be taken as fairly representing, in each case, the blasting value of the explosive tested.

Some of the mixtures given in this table are still in use as blasting agents, while others, although well known for a time to workers in mines and quarries, have, owing to various faults, either been given up entirely, or are now very little used in blasting.

An examination of the foregoing table will show the principle on which inventors of explosives go in making their mixtures. An explosive mixture usually consists of (1) a substance of itself explosive, such as nitro-glycerin or gun-cotton; (2) an oxidising agent; and (3) a carbonaceous substance to be oxidised. Sometimes the mixture consists merely of (1) an oxidising agent; and (2) of a carbonaceous substance. Such a mixture, some years ago, would not have been considered an explosive at all; indeed it can be exploded only by means of a powerful detonator, and so long as the detonators are kept apart from the mixture, it is quite safe. Even when set fire to, such mixtures will not explode. It will be observed from the table that the energy of blasting-gelatin is greater than that of nitro-glycerin. That is accounted for by the circumstance that nitro-glycerin contains a little more oxygen than is necessary for the complete combustion of itself, and that this oxygen is utilised by the carbon of the nitro-cotton contained in the blasting-gelatin. It will be observed also that the more rational mixtures are the more powerful. By rational is meant here that the ingredients of the mixture are taken in such proportions that the carbon and oxygen they contain will suit exactly to form carbonic acid at the instant of explosion. Generally speaking it may be asserted that nitro-glycerin mixtures are the best and most powerful for blasting, but they are liable to this objection, that in cold weather they become hard and frozen, and to be effective in blasting it is usually considered necessary to thaw them. For thawing them hot water pans or ovens are used, and as nitro-glycerin mixtures freeze at about 40° F., and do not readily thaw at even 10 degrees above that temperature, it may be stated that in this climate at least nitro-glycerin preparations are in a frozen state during six months of the year. However, nitro-glycerin preparations can be used in blasting as readily when frozen as when thawed, provided the miner has the necessary knowledge. Frozen dynamite is more difficult to explode than unfrozen dynamite, consequently a more powerful detonator is required to effect its explosion. That is all. But in blasting, frozen cartridges do not adapt themselves to the bore-hole so readily as the soft cartridges; but if the miner fills the hole with frozen cartridges, and then puts an ordinary detonator into a soft one, on the top of all, the explosion of the whole train will be readily effected. Frozen gelatin can be exploded easily enough by means of such a detonator as will explode the thawed material. A rifle bullet may be fired through frozen dynamite without exploding it; but a bullet from the same rifle, fired through unfrozen dynamite invariably sets it off. With blasting-gelatin the direct converse is the case. The rifle bullet passes through unfrozen gelatin without exploding it, but through frozen gelatin I have never found a bullet fail to set it off.

It will be noticed that the blasting energy of roburite and securite are nearly the same as that of No. 1 dynamite, and that the energy of tonite and potentite, which are gun-cotton mixtures, are also nearly the same. Tonite and potentite are not liable to freeze, and can, therefore, be used in winter as in summer. Tonite and potentite have a less specific gravity than dynamite and blasting-gelatin, so that a larger bulk of the former is required to do the same work as is done by a smaller bulk of the latter. In using tonite and potentite for blasting, therefore larger bore-holes are required than where nitro-glycerin preparations are used.

Securite and roburite have lately come into use as blasting agents. Those mixtures are perfectly safe when kept apart from the detonators, as they will not explode, even when set fire to, without the detonators.

To produce full explosive effect with roburite and securite, very powerful detonators are necessary.

## Communications.

## ON THE ESTIMATION OF GLYCEROL IN CRUDE GLYCERIN.

BY J. LEWKOWITSCH, PH.D., F.L.C., F.C.S.

IN a paper published by F. Filsinger, an abstract of which is to be found in this Journal, 1890, 421, objection is taken by the author to the correctness of Benedikt and Cantor's acetin method for the estimation of glycerol in commercial crude glycerin. About a year ago Filsinger published (in the Zeits. f. angew. Chemie, 1889, 3) eight analyses of a crude glycerin with the intention to show that the acetin method is far from giving concordant analyses, whereupon I proved (this Journal, 1889, 574), for various crude glycerins of different origin, that the results obtained by this method agree very closely. It is gratifying to note that in his last paper Filsinger has dropped this objection, and that his estimations of glycerol by the acetin method show a satisfactory agreement, but he still adheres to his previous opinion that by the permanganate method alone accurate results are arrived at, while the acetin method yields too high percentages for glycerol. A reason for this assertion is not given, for I for one, being practically acquainted with glycerin distilling, cannot consider the one adduced by Filsinger as a satisfactory one, viz., "that he was in a position to testify to the correctness of the permanganate method in several instances by the practical yields from the crude material employed." Fancy practical results in a works confirming the correctness of analytical methods!

As to the acetin method, it may be imagined, from a theoretical point of view, that the results could only be too low, as, judging by analogy, the process of etherification may reach a limit without being brought to an end. An acting of acetic anhydride on fatty acids (which I have recently shown takes place, Proceedings of the Chemical Society, 1890, 72) did not occur in the tests published by me, as the soap ley glycerins examined by me did not contain any. Even the "polyglycerols," although they will hardly be met with in ordinary (unadulterated) commercial glycerins, are not readily acetylated, as I convinced myself by preparing them; in fact, the acetin method allows of an estimation of any glycerol retained in these polyglycerols.

It will therefore be incumbent on Filsinger to show some other reason why the permanganate method should give more correct results, and especially to prove that no oxidation to carbon dioxide has taken place. As Filsinger takes only 0.3 gm. of crude glycerin in the permanganate test, minute errors are more likely to influence the result than in the acetin test, where 1.5—2 gm. are used.

## TABLE OF SPECIFIC GRAVITIES OF STRONG SULPHURIC ACID.

BY H. DROOP RICHMOND

(Second Chemist to the Egyptian Government).

IN reviewing the different tables of densities of strong sulphuric acid, one is struck with the want of agreement with each other that they show, amounting in some cases to .0045 in the density and nearly 1 per cent. in the strength of acid indicated.

The following table of specific gravities at 15° illustrates this well:—

Percentage.	Pickering.	Lunge and Naef.	Winkler.	Archbutt.
100	1.8384	1.8384	..	..
99.5	1.8404	1.8395	..	..
99	1.8417	1.8403	1.8400	..
98.5	1.8426	1.8407	1.8420	..
98	1.8430	1.8412	1.8427	..
97.5	1.8432	1.8413	..	1.8411
97	1.8430	1.8410	1.8430	1.8440
96	1.8420	1.8406	1.8428	1.8431
95	1.8401	1.8390	1.8427	1.8412
94	1.8374	1.8372	1.8418	1.8386
93	1.8341	1.8339	..	1.8354
92	1.8301	1.8294	..	1.8317
91	1.8255	1.8241	..	1.8268
90	1.8202	1.8185	..	1.8216

The recent work of Pickering (J. Chem. Soc. 128, 64—184) has placed at our disposal a series of determinations which is without doubt the most complete ever published, and from them I have calculated a table giving for each .0001 of specific gravity the corresponding percentages of sulphuric acid. My reasons for preferring the determinations of Pickering to all other observers are the precautions taken to observe accuracy, and the large number of determinations made, he having made nearly as many determinations as all other observers put together.

Pickering's determinations were made at four different temperatures, but it is from those at 17.925° that I have calculated my table, and I have reduced them to a temperature of 15° on the assumption that the expansion is regular between 8° and 18°, an assumption which Pickering's determinations show to be sensibly correct, and would not introduce any appreciable error into the table; I have calculated my table by the same method as used by Pickering, i.e., plotting out the densities against the percentages, taking the figures given in his paper (*loc. cit.*) and correcting them to 15°, drawing a curve and taking the figures from the curve; I have preferred to do this to taking my figures from the table of densities at 15° given by him, as I considered that all chance of error in the calculations would be eliminated; my figures on comparison agreed almost absolutely with those in his table, in no case was there a difference of more than .00002 in the density; the accuracy of the table then is beyond doubt; nowhere is there an error in the density affecting the fourth place of decimals, while except from 97 per cent. to 98 per cent. the error in the percentage will not exceed .02 per cent. at the outside.

The practical utility of the table is somewhat marred by the fact that the density reaches its maximum at 97.5 per cent., and after that slightly diminishes; but if an acid of whose strength, as indicated by the density, any doubt is entertained is diluted with about 4 or 5 per cent. of water, the table becomes as useful as before, and I have no doubt that taking the density will be the best method of determining the strength of strong sulphuric acid.

## Journal and Patent\* Literature.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### PATENTS.

*Improvements in Beaters employed in Machinery for Grinding and Pulverising Myrobalauns, Bark, Bone, Locust Beans, and other Animal, Vegetable, and Mineral Substances.* F. Firth and J. Whitehead, Dewsbury. Eng. Pat. 4151, March 14, 1889. 6d.

The improvement consists in forging the heads of revolving beaters for vegetable, and other substances, distinct from the arms, and then attaching them thereto in any suitable manner. By this method the cost is reduced, and the heads when worn can be reversed, or new ones can be substituted at a great saving of time.—E. S.

*Method of and Apparatus for Purifying Sea Water for Use in Steam Generators.* V. B. Lewes, Greenwich. Eng. Pat. 5339, March 28, 1889. 8d.

The object of the invention is to make sea water capable of being directly used for boiler feeding without the necessity of previous distillation, thereby obviating the injurious action

\* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d. .... ½d.  
Above 8d., and not exceeding 1s. 6d. .... 1d.  
" 1s. 6d., " " 2s. 4d. .... 1½d.  
" 2s. 4d., " " 3s. 4d. .... 2d.

which distilled water has on the plates of steam generators. The inventor mixes with the sea-water a salt or compound, such as carbonate of soda or potash, capable of precipitating the calcium and magnesium salts contained in the water. He then treats the mixture to boiling in a closed vessel in which the precipitate can separate, whilst the liquid is passed through filters before it reaches the boiler. The claim is for the process or method as above indicated, and a drawing is added showing one arrangement of suitable apparatus.—B.

*Improvements in the Manufacture of Clear Ice and in Apparatus Employed therein.* W. L. Wise, London. From Escher, Wyss, and Company, Zurich, Switzerland. Eng. Pat. 5592, April 2, 1889. 8d.

THE usual means employed for producing clear ice consist in agitating the water to be frozen by means of internal contrivances, such as pegs, chains, rakes, and the like, which work within stationary freezing cells. These contrivances must of necessity be removed before the coagulation of the water commences, with the result that particles of air remain occluded in the water and cause the ice to become more or less opaque. The inventors overcome this difficulty by enclosing the water in moveable cells which are themselves caused to rock, to rotate or be otherwise agitated whilst immersed in the freezing mixture. The cells may be of cylindrical shape and may be made to turn on their axes either concentrically, eccentrically, or at an angle, and may be put in motion by any convenient gearing. There are three claims and two sheets of drawings.—B.

*Improvements in the Manufacture of Metallic Hampers or Skips for Carboys and other Articles.* H. Finch, Marple, and J. Mackenzie, Yarm-on-Tees. Eng. Pat. 6770, April 23, 1889. 8d.

THE hoop-iron, or steel forming the standards, instead of being flat, is fluted or corrugated, preferably in the form U, their heads only being kept flat; and are fixed in position by binding their flat ends over, under, and round the top and bottom hoops. To increase their strength the hoops are preferably curved both laterally and longitudinally in rolling, or they may be tubular. The invention can be adapted to skips and receptacles of various shapes, and for other purposes.—E. S.

*Improvements in Presses for Compressing Semi-Fluids into Solids, commonly known as Filter-Presses.* J. Hill, Stoke-on-Trent. Eng. Pat. 7087, April 29, 1889. 8d.

THIS invention refers to filter presses used for making potter's clay, or for compressing yeast, paraffin, or other semi-fluids, in which porous slabs are used as the filtering medium. The filter press is made in several sections, each section being formed of two or more porous slabs of suitable thickness, fixed in frames and bolted together side by side, so as to leave spaces between each set. The faces of the slabs are grooved to form passages for the liquid. The semi-fluid is forced into the spaces, the liquid passing through the slabs, whilst the solid matter is retained in the space. When the spaces are filled, the solid matter is removed, and the slabs are taken out and turned half round, so that the liquid in flowing through now clears the pores and prevents them being clogged. There are four claims and three sheets of drawings.—E. S.

*Improvements in and relating to Apparatus for Evaporating Sea and other Water for Obtaining a Supply of Fresh Water.* J. Newton, London, and D. A. Quiggin, Liverpool. Eng. Pat. 8139, May 16, 1889. 8d.

THIS is an improvement on Eng. Pat. 538 of 1889 (this Journal, 1890, 43) granted to the same inventors, the

object being to reduce "priming" in the evaporator, to facilitate the removal of scale on the heating surfaces of the feed-water heater, and to more easily keep a constant level of water in the evaporator. The first object is accomplished by inserting in the evaporating liquid vertical circulating tubes, open at both ends, and entirely immersed, thereby causing the hot water and vapour to ascend and the cold water to flow downwards with regularity. The removal of the scale is facilitated by attaching the feed-heating tubes to the cover of the heater box, and thus making them removable with the cover, for cleaning. A fixed level of the water is maintained in the evaporator by means of adjustable and self-acting floats and valves, for details of which, and of the other contrivances, the two sheets of drawings must be consulted. There are six claims.—B.

*Improvements in Brewers' and other Thermometers.* J. J. Hicks, London. Eng. Pat. 8184, May 16, 1889. 8d.

THESE improvements in brewers' thermometers refer to the shape of the surrounding case used for the retention of some of the liquor of which the temperature is to be taken, to self-acting means for clearing the scale of froth, to means for facilitating the reading of the temperature, for cleaning all parts after use, and to other details of construction or arrangement. The specification contains eight claims, and is accompanied with one sheet of drawings.—B.

*Certain Improvements in Filters.* E. M. Knight, San Mateo, U.S.A. Eng. Pat. 648, January 14, 1890. 6d.

THIS invention relates to those filters in which a fibrous or porous material is used as the filtering medium, and has for its object, (1), to prevent the leakage of the unfiltered into the filtered liquid; (2), to render the percolation of the liquid through the filter free and uniform; (3), to simplify and expedite the process of filtration; and (4), the cleansing of the filter and renewal of the filtering medium.

The filtering frame is made, preferably, of iron, and has a number of transverse bars to support the filtering medium, and is of such a thickness that when the sheets of asbestos cloth are stretched over each side there is a considerable space between them, which forms a chamber into which the liquid to be filtered flows. The asbestos cloth is covered with a paste of filtering medium, rubbed into the fibre of the cloth, and is further retained there by a wire netting, the whole being held together at the edges by clamping-plates and bolts, thus preventing the excess of any liquid to the interior chamber without first passing through the filter. The filter is cleaned by removing it from the frame and plunging it into the fire.—E. S.

*Improvements in Refrigerating Machinery.* T. B. Lightfoot, London. From C. Linde, Wiesbaden, Germany. Eng. Pat. 1875, February 4, 1890. 8d.

THESE improvements apply to refrigerating machinery in which cold is produced by evaporation of a volatile liquid, the vapours being then compressed by machinery and subsequently cooled in condensers, in order to act again by evaporation. The improvements mainly refer to means for counteracting the prejudicial effect of "dead spaces" in the compressing cylinders, and of want of tightness in valves and stuffing-boxes, which defects are more specially noticeable in cases of great differences of pressures and of temperatures existing between the evaporator and condenser.

The method recommended is that of compressing and cooling by stages, the compressors being arranged in such a way that the vapours subjected to the higher stages of compression are operated upon in those ends of the cylinders only in which there are no stuffing-boxes.

One such compressing arrangement is shown in the accompanying figure, which also illustrates a method of combining the vapours from a second evaporator, that may

or may not be of higher pressure and temperature than those from the first.

In the figure  $C_1$  and  $C_2$  are double-acting compressing cylinders, both ends of  $C_1$  and the stuffing-box end of  $C_2$  being coupled by pipes to draw from the evaporator at A

and deliver into the receiver R, from which the other end of compressor  $C_2$  draws and finally delivers at increased pressure into the condenser at D. The low-stage compressors may also be made to draw from the second evaporator at B, or the vapours from the latter, if of higher pressure and

temperature than those from A, can pass directly into the receiver R, as shown by dotted lines. Other combinations may be made by a change in the pipes and valves. The specification shows other arrangements of compressors working by stages, also of cooling apparatus acting on the same system; and there are five claims.—B.

This shows a gain of 6 per cent. with hot air. The quantities of water evaporated during a week's trial with three boilers were, using hot air, 170,220 litres, and, using cold air, 151,868 litres, the consumption of coal being 21,900 kilos. in the former case and 20,700 kilos. in the latter. The average temperature of the air leaving the chamber was 53.7°, but as it afterwards passes under the bottom-flue its temperature on arrival at the fire-bars must be much higher, but as yet it has not been determined; the average temperature of the cold air was 20.9°; the average pressure in the boilers was 4.25 kilos. using hot air, and 4.30 kilos. using cold air, and in the former case 1.8 per cent. less cinders were produced. In a second experiment, made with the same coal and under similar conditions, but with three other boilers, the following average results were obtained:—

## II.—FUEL, GAS, AND LIGHT.

*The Influence of the Temperature of the Air supplied to Boilers in the Yield of Steam.* Poupardin. Bull. Soc. Ind. Mulhouse, 1889, 615—619.

THE results obtained by Meunier and Scheurer-Kestner showing the different yield of steam in summer and winter from the same coal, led the author to think that besides the cooling of the mass and loss by radiation, the temperature of the air-supply was a factor of importance. A preliminary experiment, made by conducting air through a wooden tube from the top of the boiler to the furnace, showed that more steam was produced than when the air was taken through a similar tube from the front of the boiler. The erection of a set of six new boilers at their Mer-Rouge works by the firm of *Schlumberger Fils* gave the author an opportunity of making a thorough trial with heated air. The flues and masonry were constructed to allow a system of air-pipes to be fixed somewhat after the fashion of a Green's economiser. The air-pipes were placed upright and left open at the top for the admission of air, communicating below with a chamber, with which was connected a pipe running at the back of the boilers, which in turn supplied pipes leading under the boilers to the furnaces. Arrangements were made for shutting off the hot air when desired, and using cold air in the ordinary way. The boilers have been tested by a year's working, and an increased yield of steam has invariably been obtained when hot air was used, as may be seen in the following example:—

	Gross Yield of Steam per Kilo. of Coal consumed.	Yield of Steam, Weight of Cinders deducted.
With hot air.....	Kilos. 7.77	Kilos. 8.95
With cold air.....	7.33	8.63
Gain with hot air.....	0.44	0.32

	Gross Yield of Steam per Kilo. of Coal consumed.	Yield of Steam, Weight of Cinders deducted.
With hot air.....	Kilos. 8.70	Kilos. 10.98
With cold air.....	8.09	9.34
Gain with hot air.....	0.61	0.64

This represents a gross gain of 7.5 per cent. of steam or 6.8 per cent. after deduction of the weight of cinders has been made. The average temperature of the air leaving the chamber was, in this experiment, 49.1°, that of the cold air being 24°; the average steam-pressures were, with hot air, 4.30 kilos.; with cold, 4.26 kilos.; the quantities of water evaporated were 175,810 litres with hot air, and 177,370 litres with cold, the consumption of coal being, with hot air, 20,300 kilos., and 21,900 kilos. with cold; the temperature of the feed-water was 35° in the case of the hot air experiment and 39.1° in the other case; using hot air there were contained in the steam  $(606.5 + 0.305 \times 155 - 35) \times 8.7 = 5,382$  heat units, the temperature of the steam being in each case about 155°, that of the feed-water in this case 35°, and the gross yield of steam 8.7 kilos. per kilo. of coal burnt; using cold air there were contained in the steam  $(606.5 + 0.305 \times 155 - 39.2) \times 8.09 = 4,979$  heat units, there being thus a gain of 411 heat units per kilo. of coal consumed with hot air. The specific heat of air being 0.2377, and the difference of temperature in the air-supplies being  $49 - 21 = 28^\circ$ , each kilo. of hot air has brought with it  $0.2377 \times 25 = 5.94$  heat units. Had the 411 heat units gained been brought in the hot air they would thus require  $\frac{411}{5.94} = 69.2$  kilos. of air or 53 cubic metres at 0°, whereas only about 15 cubic metres are calculated for each kilo. of coal.

The gain realised with hot air compares well with that realised with a Green's economiser. Taking the second experiment again, when the air was heated, 175,810 litres of

water entered the economiser at  $35^{\circ}8'$ , leaving the same at  $100^{\circ}5'$  on the average, representing an increase of heat of  $175,810 (100^{\circ}5' - 35^{\circ}8') = 11,374,907$  units; with cold air  $177,370$  litres entered at an average temperature of  $39^{\circ}2'$ , leaving at  $98^{\circ}1'$ , representing a gain of  $10,447,093$  heat units. By the use of hot air, as shown above, there was a gain of  $411$  heat units per kilo. of coal burnt, or for  $20,200$  kilos.  $8,302,200$  heat units.

It is pointed out that these results must not be taken as conclusive, as it remains to be seen whether the arrangements adopted, size of the pipes, chamber, &c., are the best, the author intimating his intention to resume his experiments in this direction.—E. B.

#### *The Spontaneous Ignition of Coal.* J. Gas Lighting, 55, 645.

At the Thirty-first Session of the Institution of Naval Architects, recently held at the Society of Arts, Adelphi, a paper on the above subject was read by Professor Vivian B. Lewes.

The author began by referring to the appointment of a Royal Commission in 1875, on the proposition of the Board of Trade and a Committee of Lloyds, to investigate the causes of the spontaneous ignition of coal cargoes, which had entailed serious loss of life and destruction of property. The Commission was assisted by Dr. Percy and Mr. (now Sir Frederick) Abel; and the result of their labours was the production of a report containing much sound advice for the guidance of persons employed in the shipment of coal. Nevertheless, accidents from the spontaneous ignition of cargoes continued; and between 1875 and 1883, no less than 57 coal-laden vessels were in consequence known to have been lost, while during the same period 328 were missing from unknown causes, though probably a large proportion of these losses were due to the one mentioned. In view of this fact, it was suggested to the author that an inquiry into the causes and possible prevention of this serious evil was greatly needed in the Royal Navy as well as in the merchant service; and therefore he undertook it, and laid the results before the members of the Institution.

The author proceeded to point out that, besides the carbon and hydrocarbons, coal contains certain mineral substances, as sulphate of lime or gypsum, silica and alumina, whilst in nearly all kinds there is to be found disulphide of iron and coal "brasses," or pyrites. Of these constituents, those that are likely to produce heat and cause spontaneous ignition in newly-won coal, are the carbon, hydrocarbons and brasses, which when they come into contact with air and moisture, give rise to certain chemical actions. He then described at length the influence of each of these constituents in the production of heat. Taking carbon first, he remarked that it is one of those substances which possess to an extraordinary degree, the power of attracting and condensing gases upon their surfaces—the power varying with the state of division and density of the particular form of carbon used. In the case of newly-won coals, the least absorptive would, he said, take up  $1\frac{1}{4}$  times, while others would absorb three times their own volume of oxygen. This absorption is very rapid at first, but gradually decreases; and it is influenced to a very great extent by temperature. Air-dried coal absorbs oxygen more quickly than wet coal.

Dealing in the next place with the action of the bituminous constituents of coal in causing spontaneous ignition, the author explained that all coal contains a certain percentage of hydrogen, which is in combination with some of the carbon, and also with the nitrogen and oxygen, and forms with them the volatile matter in the coal. The amount present in this condition varies very largely; being very small in anthracite and very great in cannel and shale. When the carbon of the coal absorbs oxygen, the compressed gas becomes very chemically active, and soon commences to combine with the carbon and hydrogen of the bituminous portions, converting them into carbon dioxide and water. This chemical activity increases rapidly with rise of temperature; so that the heat generated by the absorption of the oxygen causes the latter to rapidly enter into chemical combination. Chemical combination of this kind—*i.e.*,

oxidation—is always accompanied by evolution of heat; and this further rise of temperature again increases rapidity of oxidation, so that a steady rise of temperature is set up. This taking place in the centre of a heap of small coal, which, from the air and other gases enclosed in its interstices, is an admirable non-conductor of heat, will often cause such heating of the mass that if air can percolate slowly into the heap in sufficient quantity to supply the necessary percentage of oxygen for the continuance of the action, the igniting-point of the coal would be soon reached. It has been suggested that very bituminous coal (such as cannel, shale, and coals containing schist) is liable to spontaneous ignition from the fact that a rise in temperature would cause heavy oils to exude from them, which, by undergoing oxidation, might cause rapid heating. Experiment, however, not only shows that this is not the case, but that the heavy mineral oils have a remarkable influence in retarding heating.

The action of iron disulphide, pyrites, or "brasses," in promoting spontaneous ignition, was next discussed. The author said that ever since Berzelius first expressed the opinion that the heat given out by the oxidation of iron disulphide into sulphates of iron might have an important bearing on the heating and ignition of coal, it had been adopted as the popular explanation of that phenomenon; and although the work of Richters clearly proved this not to be the case, the old explanation was still given. Dr. Percy, in 1864, pointed out that probably oxidation of the coal had also something to do with spontaneous combustion—a prediction amply verified by Richters' researches some six years later. This disulphide of iron was found in coal in several different forms—sometimes as a dark powder distributed throughout the mass of the coal, and scarcely to be distinguished from coal itself. In larger quantities it often formed thin golden-looking layers in the cleavage of the coal, whilst it sometimes occurred as large masses and veins, often from 1 in. to 2 in. in thickness; but inasmuch as these masses of pyrites were very heavy, they rarely found their way into the screened coal for shipment, many hundreds of tons of these brasses being annually picked out from the coal at the pit's mouth, and utilised in various manufacturing processes. When the air was dry, the pyrites underwent but little change at ordinary temperatures. In moist air, however, they rapidly oxidised when in a finely-divided condition—the first action being the formation of ferrous sulphate and sulphur dioxide, together with the liberation of sulphur; the relative amounts of the two latter being regulated by the temperature and the supply of air, whilst longer contact with moist air converted the ferrous sulphate into a basic ferric sulphate generally termed "misy." It was during this process of oxidation that the heat supposed to cause the ignition was evolved. But when it was considered that some of the coals most prone to spontaneous combustion contained only 0.8 per cent. of iron pyrites, and rarely more than 1.25 per cent., the absurdity of imagining this to be the only cause of ignition became manifest. If 100 lb. of coal were taken, and the whole of the pyrites in it concentrated in one spot and rapidly oxidized to sulphate, the temperature would barely be raised to  $100^{\circ}$  C. if all loss of heat could be avoided. The author had carefully determined the igniting-points of various kinds of coal, and found them to be as follows:—

Cannel.....	$698^{\circ}$ F. = $370^{\circ}$ C.
Hartlepool.....	$766^{\circ}$ F. = $408^{\circ}$ C.
Lignite.....	$842^{\circ}$ F. = $450^{\circ}$ C.
Welsh steam.....	$870^{\circ}$ F. = $477^{\circ}$ C.

So that no stretch of imagination could endow the small trace of pyrites scattered through a large mass of coal, and undergoing slow oxidation, with the power of reaching the needful temperature. Richters fully realised this point, and discarded the idea of the pyrites doing anything more than adding their mite to the causes which bring about rise of temperature. In this, however, Lewes thought Richters was mistaken, his own experiments pointing to the fact that they might increase the liability to ignition when present in large quantities, and do so by liberating sulphur under certain conditions. A still more important part played by the pyrites, is that as they become oxidised to ferrous sulphate they swell in size, and so tend to split up the coal

into small pieces, and, by exposing a large extent of fresh surface to the air, cause increase of temperature and energetic chemical action.

The author, Lewes, then traced the actions which culminate in ignition. He said that on newly-won coal being brought to the mouth of the pit, it at once began, by virtue of its surface action, to absorb oxygen from the air. Unless piled in unusually large heaps, and a good deal broken, it did not however, as a rule, show signs of heating, as the exposed surface was comparatively small; and the air, finding its way freely between the lumps, kept down the temperature. The coal was now screened, and the obtrusively large lumps of brasses picked out. It was then put into trucks, and enjoyed the disintegrating processes of joltings and shuntings innumerable—every jar adding to the percentage of small coal present, and a corresponding increase in the size of the surface exposed to the air. Arrived at the docks, it had to be transferred from the truck to the ship, which was done by one of the numerous forms of tips, shoots, or spouts employed for the purpose; and it was during this operation that more harm was done than at any other period. The coal first shot into the vessel was, by reason of the distance which it had to fall, broken down into small lumps, and, having to bear the impact of the succeeding load falling upon it from a height, rapidly became powdered into slack; whilst the succeeding loads, falling in on the cone so formed, became more or less broken down, so that by the time the cargo was all taken in, a dense mass of small coal was to be found under the hatchway. It was invariably at this point that heating took place, as the large surface exposed fresh to the air by the breaking down of the coal caused rapid absorption of oxygen, and consequent rise of temperature. This set up chemical combination between the oxygen absorbed by the coal and the hydrocarbons and coal "brasses." The combination of the "brasses" with oxygen caused the swelling of the oxidised mass and the splitting up of the coal. Fresh surfaces were exposed, and more absorption of oxygen took place; and the igniting-point of the sulphur vapour and sulphur compounds distilled out of the pyrites was reached, and rapidly raised the temperature to the igniting-point of the coal. It was only, however, in cases where large quantities of dense coal brasses were present, that this action could occur. On examining the evidence to be obtained as to the conditions under which spontaneous ignition of coal in ships usually takes place, Lewes found that the liability to such accidents increases with (1) the tonnage of the cargoes, (2) the ports to which shipments are made, (3) the kind of coal of which the cargo consists, (4) the size of the coal, (5) the shipping of coal rich in pyrites while wet, (6) the ventilation of the cargo, and (7) the rise in temperature in steam colliers due to the introduction of triple-expansion engines and high-pressure boilers.

Having discussed the chemical and physical conditions which lead to the spontaneous ignition of coal, the author proceeded to formulate precautions tending to prevent such disasters. These had reference to the choice of coal for shipment to distant ports, and to the precautions to be taken during shipment and when the coal is on board. He advised that the coal should be as large, free from dust, and have as little "smalls" as practicable. It was better as free from pyrites as possible, in order to prevent disintegration after shipment; and it should contain, when air-dried, not more than 3 per cent. of moisture. No coal should, he said, be shipped to distant ports until at least a month had elapsed after it was brought to the surface at the pit's mouth. Every precaution should be taken to prevent the breaking up of the coal while being taken on board, and on no account should any accumulation of fine coal be allowed under the hatchways. When possible, the coal should be shipped dry, as external wet, by producing oxidation of the pyrites, caused disintegration. When the coal had all been taken in, it should be battened down, and the hatches not opened again until the vessel reached her destination; the only ventilation allowable being a 2-inch pipe just inserted into the crown of each coal compartment, and led 12 feet up the nearest mast—the top being left open. This would be quite sufficient to allow free egress to any gases evolved by the coals, but would not allow undue

access of air. Into the body of the coal cargo itself would be screwed, at regular intervals of about 6 feet, iron pipes, closed at the bottom, and containing electrical alarm thermometers, set at a certain temperature, the attainment of which would be indicated by the ringing of a bell, which would not cease until the temperature had again fallen, and then the spot in which the heating had taken place would be indicated by an index-board. The existence of over-heating having been reported by the bell, and recorded by the index, the author offered suggestions for suppressing it. He advocated the injection of compressed carbonic acid gas, and explained his plan as follows:—The nozzle attached to the screw valve on the bottle of condensed gas would have a short metal nose-piece screwed on to it, the tube in which would be cast in solid, with an alloy of tin, lead, bismuth, and cadmium, which could be so made as to melt at exactly 200° F. (93° C.). The valve would then be opened, and the steel bottle buried in the coal during the process of loading. The temperature at which the fusible metal plug would melt is well above the temperature which could be reached by any legitimate cause, and would mean that active heating was going on in the coal. Under these conditions, the pressure in the steel cylinder would have reached something like 1,700 lb.; and the moment the plug melted, the whole contents of the bottle would be blown out of it into the surrounding coal, producing a large zone of intense cold, and cooling the whole of the surrounding mass to a comparatively low temperature. The action, moreover, would not stop here, as the cold, heavy gas would remain for some time in contact with the coal—diffusion taking place but slowly through the small exit-pipe. When coal has absorbed as much oxygen as it can, it still retains the power of taking in a considerable volume of carbonic acid gas; and when coal has heated, and then been rapidly quenched, the amount of gas so absorbed is very large indeed, and the inert gas so taken up remains in the pores of the coal, and prevents any further tendency to heating. Indeed, a coal which has once heated, if only to a slight degree, and has then cooled down, is perfectly harmless, and will not heat a second time. It is not by any means necessary to replace the whole of the air in the interstices of the coal with the gas, as a long series of experiments show that 60 per cent. of carbonic acid gas prevents the ignition of the pyrophoric substances. A hundred cubic feet of gas can be condensed in the liquid state in a steel cylinder 1 foot long and 3 inches in diameter; and it has been shown that a ton of coal contains air spaces equal to about 12 cubic feet. One of these cylinders would therefore have to be put in for every 8 tons of coal, and these would be distributed evenly through the cargo, and near the alarm thermometers, which would be set to ring a degree or two below the point at which the fusible plug would melt. The bell ringing in the captain's room would warn him heating was taking place, and the bell would continue to ring until the cylinder had discharged its contents, and had cooled down to a safe degree, so that the whole arrangement would be purely automatic, and yet the officers would know if everything was safe. If the precautions advocated were taken, no danger could arise until the arrival of the ship at her destination, and the commonest precautions would then suffice.

In conclusion, the author remarked that the question of preventing the heating and ignition of stores of coal on land and ready for use in bunkers, could not be met so well by the use of the liquid gas; and in these cases it would be found beneficial to dress the coals with a little tar or tar oil, which would close the pores, and to a great extent prevent oxidation. He believed this was advocated by Lachman about 1870. Crude petroleum in small quantities for this purpose would also be found valuable, for it had no tendency to oxidise itself, and lowered the tendency in other bodies, besides coating them and so preventing access of oxygen.

In the discussion which followed, Professor Elgar, referring to the statements in the early part of the paper that, between the years 1875 and 1883, no less than 328 coal-laden vessels were missing from unknown causes, and that a large percentage of these losses were undoubtedly due to spontaneous

ignition, argued that there were a number of other causes which might account for their disappearance; and he then gave some particulars as to the losses during the three years from 1881 to 1883. In that period there were 23 known losses of vessels from spontaneous combustion of coal, but only one of these was a steamer—the other 22 being sailing vessels, the larger number of which were built of wood. He thought that one cause of spontaneous combustion in wooden ships was the impossibility of keeping the holds dry, and to the coal becoming damp and generating heat. Under the American law, ships registered in the United States were obliged to be fitted with steam-pipes in their holds, for the purpose of dealing with fire.

*Coal in the South-East of England.* W. Whitaker. Soc. of Arts J. 1890, 543–553.

For many years the presence of an underground range of old formations at no enormous depth in the south-east of England has been thought to exist by geologists, although in this tract only newer rocks crop out to the surface. The possibility of coal measures to be found amongst these older rocks gave zest to inquiry. The formations which come to the surface in and around London belong to the lower part of the Tertiary group, and to the upper part of the Secondary group, viz., the Cretaceous series, so called from its containing the chalk which comes to the surface near London and is found beneath the Tertiary beds in deep wells. The author proceeds to state that the various underlying members of the Cretaceous series were found to rise up and to crop out on the south in the following order from beneath the chalk in the tract known as the Weald:—

1. Upper Greensand. 2. Gault. 3. Lower Greensand.
4. Weald Clay. 5. Hastings Beds.

The general structure of the south-east of England in section is represented by a gently waved line with a central crest (the Weald), and a hollow on either side (the London and the Hampshire basins), the line being from north to south. Mr. Godwin-Austen worked out the idea (based on various observations) that the Lower Cretaceous beds along the slight trough of the London basin were likely to be interrupted underground by the uprise of older formations, against the flanks of which some of the Cretaceous beds would be found to thin out.

Now, the author points out that there is on the Continent a set of coal-fields with other rocks older than the coal measures along a curved line from Dortmund and Elberfeld (Germany) by Aachen, Liege, Namur, Charleroi, Valenciennes, Douai, and Bethune towards Calais whence the line has now been traced to Dover by the successful experiment of Sir E. Watkins and Professor Dawkins. In the west of England are the coal-fields of South Wales and Bristol. In the eastern part of this continental tract the coal measures are mostly at the surface; in the western they are covered by newer formations. The same may be the case in England eastward from the coal measures which are at the surface, and it is not improbable that the coal discovered at Dover has, in some way or another, underground connections with the western coal-fields.

The above-mentioned theory of an underground uprise of older rocks has been verified by various borings for water in the London basin, the borings being from 797 to 1,239 ft. deep. In the majority of cases the Gault was found to be underlain at comparatively little depths by old rocks, viz., Jurassic, Lower Carboniferous, Devonian, and Silurian beds, and some beds of doubtful age (perhaps New or Old Red sandstone). The author thinks that the variety of formations thus found suggests the possibility of the presence of other rocks being proved in other places. Of other borings beyond this district the proving of coal measures beneath Jurassic and Triassic rocks at Burford in Oxfordshire is of interest, and the finding of Carboniferous and older rocks by borings in and near Northampton. Two borings are remarkable in the south-east of England: the Subwealden boring near Battle (1872–76) through the Upper Jurassic rocks to the Oxford clay, and the Dover boring for coal in February last. This last boring, at the foot of Shakespeare Cliff, first passes through the Lower Chalk, Gault and Lower

Greensand, then through a series of Jurassic beds, until it reaches coal measures at a depth of 1,160 ft.

All these experiences and experiments lead the author to the following views and conclusions which may serve as a guide for further work in connection with this important subject.

1. We are to a great extent acquainted with the nature of the formations which have to be pierced to reach coal measures, and we can estimate the thickness of some of these formations.

2. The uprise of older rocks in Belgium and France seems to be in underground connection with the like uprise in the west of England; and coal-basins, separated by older rocks, are likely to occur underground in the unexplored part of this region in a similar manner as in the proved parts.

3. In the proved parts the coal measures contain profitable beds of coal, and at workable depths; therefore the same may be supposed for the unknown parts in the south-east of England.

4. The sites of the coal-basins can only be found by experiment, and we must be prepared to find that not all experiments will be as successful as the first one.

5. The places of the previous borings which reached some of the older rocks, must be avoided, as it is unlikely to meet with coal there.

6. Some of the borings which have already been carried to a considerable depth, ought to be continued, e.g., at Chatham a boring has reached the Oxford clay, and judging by the northerly thinning of the Jurassic rocks (from the Weald), a few hundred feet more down might bring a decisive result. For a similar reason St. Margaret's may be recommended, where a boring exists that has reached the Gault.

7. The Lower Cretaceous (including the Wealden) and the Jurassic beds thicken vastly southward from the valley of the Thames, a fact which has to be considered as well as the obvious advantage of commencing at a low level, for it is unnecessary to pierce a hill if a valley is in close proximity.

8. Magnetic properties and geological characters of various districts seem to bear certain relations one to the other, as Professor's Rücker and Thorpe have shown. This might afford hints about places to be avoided in searching for coal measures underground.

9. All the deep exploration heretofore noticed, being made by boring, the author recommends shaft-sinking, especially in places where there is little to fear from water. The beds to be pierced are not hard, and it is obvious that a shaft affords much more conclusive proofs and better means of investigation (e.g., horizontal working) than a bore-hole.

The author concludes his paper by stating that the geological structure of a large tract of country points to hidden coal-fields, lying in the folds or at the flanks of older rocks, in the south-east of England. To ascertain their position, trial work (perhaps of great extent) on a large area has to be done, and success must be expected to alternate with failure. The finding of these coal-fields would add greatly to the national wealth.—H. S.

*Annual Report of Gas Inspector to the Senate and House of Representatives of the Commonwealth of Massachusetts.* January 1890.

The inspector, C. W. Hiuman, states that ten towns are supplied with a gas made from petroleum or some of its products. Some of these towns use the pure gas, but generally more or less air is mixed with it to render the gas less liable to smoke. This addition of air reduces the illuminating value of the gas, but only slightly for the amount of air usually added. The gas made from petroleum contains so little sulphur that it was not thought necessary to determine it, especially as only about one-half as much of this gas is required to produce a certain quantity of light as when common coal is used.

The legal maximum for carbonic oxide is 10 per cent. of the total volume of the gas; coal gas usually contains from 5 to 8 per cent., and water-gas, as usually made, from 25 to 30 per cent. of carbonic oxide. It is evident that about 15 per cent. of water-gas can be added to coal gas and the resulting mixture yet contain less than the legal maximum of carbonic oxide.

Several of the companies using water-gas applied, under an Act passed in 1888, for leave to manufacture gas containing more than 10 per cent. of carbonic oxide. At Amesbury, Athol, and Spencer the gas has been found on three consecutive inspections to contain more than 10 per cent. of carbonic oxide, and the companies have been notified that a fine was due; at Athol, some time in the past summer, coal gas was substituted for water-gas and has since been used. More than 10 per cent. of carbonic oxide has been found in the gas of several other companies.

Two samples of water-gas were found on analysis to have a low illuminating value, although they contained a high percentage of illuminants; the percentage of carbonic oxide was also low for water-gas. The degree of heat used in the manufacture of these gases seems to have been too high for the amount of oil used. It seems certain that the hydrocarbons in these two gases were of less illuminating value than an equal volume of the hydrocarbons in coal gas; and it also seems certain that marsh gas has some value as an illuminant, as is shown by the following fact:—Two samples of gas which were found to contain practically the same percentage (14·4) of illuminants had an illuminating power of 28·3 and 22·1 candles respectively; this difference was due to the fact that the one contained 30·54 per cent. of marsh gas and 9·15 per cent. of carbonic oxide, the other (the poorer) 17·18 per cent. of marsh gas and 21·74 per cent. of carbonic oxide, the quantities of the other constituents being practically the same in the two samples. A knowledge of the percentage of illuminants in a gas, if nothing else about its composition be known, is therefore, very little guide to a knowledge of the illuminating power of the gas.—F. S. K.

#### PATENTS.

*A Process and Apparatus for Preparing Hydrogen and Carbonic Oxide Gases.* G. W. Hart, London. Eng. Pat. 7741, May 9, 1889. 8d.

THE process described is continuous and consists of the following operations:—

I.—Carbon dioxide is generated from chalk or other carbonates by heat or by treatment with acid, and such gas is passed over heated carbon, whereby it is converted into carbonic oxide.

II.—Steam is passed through retorts containing heated scrap iron, whereby hydrogen is evolved and the iron is converted into oxide, the hydrogen being led away for use.

III.—The carbonic oxide produced in operations I. or IV. is passed over the iron oxide formed by operation II., whereby the oxide of iron is reduced to metal and the carbonic oxide is reconverted into carbon dioxide.

IV.—The carbon dioxide so produced is passed over heated carbon and reconverted into carbonic oxide, which is led into a gas-holder, though a portion may be used for operation III.—F. S. K.

*Improvements in the Method of and Apparatus for the Manufacture of Water-Gas.* G. Rose, A. Baird, and M. B. Baird, Glasgow. Eng. Pat. 7812. May 10, 1889. 8d.

A CLOSED, cast-iron retort, charged with coke or other carbonaceous material, mixed or not with iron scrap or nails, is heated to a high temperature by means of one or more flames from liquid fuel, and steam, superheated or not, is admitted into the centre of the retort, together with hydrocarbon, or other oil if desired, the gas generated being then passed into a cooling and cleaning apparatus. The steam is generated by means of a coil placed in the funnel or flue of the generator furnace.—F. S. K.

*Improvements in Compounds to be used for manufacturing Illuminating Gas, the Prevention of Stoppages in Ascension Pipes, and the Deposition of Naphthalene.* S. B. Darwin, Portsea. Eng. Pat. 8263, May 17, 1889. 4d.

THE objects of this invention are to utilise coal tar and breeze, together with shale, petroleum or paraffin oil, or coal or cannel tar oil, or other suitable oil, with or without the addition of lime, for preventing stoppages in ascension pipes and the deposition of "naphthalene," while the gas produced by the use of this mixture as an addition to coal is of superior quality.

A scoopfull, or other suitable quantity, of a mixture of 160 gallons of tar, 28 gallons of oil, and 96 bushels of breeze, moistened with water if too dry and with or without the addition of lime, is placed on the top of the coal either when charging, or the retort is opened about an hour before the coke is drawn, and the mixture laid on the top of the red-hot coke.

The proportions given above may be varied according to the materials employed, but the mixture should be sufficiently hard to keep from running, and so made that it is not liable to be set on fire by hot drags, &c.—F. S. K.

*Improvements in Fastenings for Retort Lids.* G. King, Beckton. Eng. Pat. 9375, June 5, 1889. 8d.

THE object of this invention is to provide the lid of a gas retort with fastenings which will make a tight joint between the lid and mouthpiece, and in which the working parts of the fittings are protected from dirt. The lid is supported by a cross-bar by means of a bolt passing through a lug on the door. At one end of the cross-bar is a hole in which fits an eccentric boss attached to the lever closing the door. The cross-bar and lever when in position on the mouthpiece are fitted between two hinge-lugs cast on one side of the mouthpiece, and are retained there by a pin. The lid, cross-bar, lever and pin being fitted together on the mouthpiece, are free to swing round the hinge pin, the bearing surfaces being protected from dirt by the lugs. A catch and rest are fitted to a catch-box cast on the other side of the mouthpiece, and are held in position by a pin. The rest is a fixture, while the catch is free to swing round the securing pin so far as is necessary to allow the catch to be engaged or disengaged from the end of the cross-bar. A modification of the above is shown on the two sheets of drawings accompanying the specification. There are four claims.—E. S.

*New or Improved Artificial Fuel.* W. W. Popplewell, London. From H. Corried, New York, U.S.A. Eng. Pat. 2611, February 18, 1890. 4d.

THE patentee's improved fuel consists essentially of a mixture of pulverised coal dust, coal, culm, coke, peat, straw, and like material, mixed with a binding substance obtained by concentrating the waste liquor of the sulphite cellulose process until it has about the consistency of a syrup.

The proportions of the wood lixivium and pulverised combustible material vary according to the concentration of the former and the nature of the latter. In the case of very rich coal 5–6 per cent. of the highly concentrated lixivium is added: if the coal be not very rich, 10 per cent.

Combustible bricks can also be made by first mixing the pulverised combustible material with tar or molten pitch, and the wood lixivium with chopped straw, and then combining these two mixtures.—F. S. K.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*The Sundsha Naphtha Region of the Northern Caucasus.*  
Chem. Zeit. 14, 159.

ALTHOUGH the occurrence of naphtha in the territory situated between the Sundsha river and the main mountain range of the Caucasus east of Wladikawkas has been known for some time, borings have only been commenced recently by a number of local capitalists, the initiative in this direction having been taken by General Panin. In 1888 the average daily yield of crude oil amounted to 150 puds per well; in 1889, after deepening, it rose to 300 puds, and at the present time, the depth of the wells having been still further increased, the yield may be put down at 600 puds. The crude oil has a colour ranging from dark brown to black. The specific gravity is 0.886, and on distillation the oil yields from 3 to 4 per cent. of petroleum spirit of 0.700 sp. gr. and from 20 to 25 per cent. of kerosene, which has a flashing point of 25°.—D. B.

*On the Refining of the Heavier Paraffin Oils of Lignite-Tar.* E. von Boyen. Chem. Zeit. 14, 267—269, 289—291.

MANY patents are being constantly secured for refining mineral oil; there is a fair amount of literature, also, upon the subject, but it is on the whole useless for practical men on account of the different nature of oils from various sources.

Of the class of very heavy mineral oils such as those of lignite-tar very little has been published. They differ in their chemical composition from Russian and Galician oils, and consequently in their methods of refining. They most resemble the heavy mineral oils from Scotch shale oils, yet as there are marked differences the same method of refining cannot be entirely adopted.

The following facts are chiefly from the personal observations of the author:—The neutral hydrocarbons of lignite-tar boiling above 300° and previously freed by treatment from crystalline paraffin, when treated with concentrated sulphuric acid and caustic soda and distilled, distil with a steady uninterrupted rise of the thermometer. The fractions, taken every 5°, are very similar. The specific gravity and viscosity of the oil increases with the boiling point, while the colour becomes darker and the smell weaker. If each fraction be repeatedly agitated with 50 per cent. of concentrated sulphuric acid until no further action takes place, only an unimportant percentage of the original oil is left, the remainder being converted into a black mass which rapidly collects at the bottom of the vessel, technically known as "acid-tar" (Säureharz). It consists of sulphonic acids which are soluble in water.

If only 3 per cent. of acid be used then the black mass obtained more resembles resin and is insoluble in water, further treatment of the oil with acid giving products soluble in water. The residual oil gives a milky emulsion on shaking with water, from which there separates on standing in a warm place for a few days a black oil of sp. gr. .900.

Fuming sulphuric acid has the same effect, and crystalline sulphonates can be prepared from the residue. Fuming nitric acid dissolves the oil, forming a deep red-coloured solution, from which on addition of water a hard amorphous resinous mass separates, easily soluble in hot alcohol, and which can be crystallised. These reactions disprove the pre-existence of paraffins. The oil on heating with potassium hydrate volatilises all but a small portion, which is left as a black humid mass. With potassium bichromate and sulphuric acid the oil becomes viscous and red coloured by energetic oxidation, and with potassium permanganate in alkaline solutions acetic acid is formed.

All these reactions show that this oil differs in its properties from the mineral oil yielded ready made from the earth; and they give also a hint as to the method of refining.

In the ordinary process of rectifying Russian and Galician oils, the treatment with sulphuric acid, in order to

remove the small quantity of aromatic and unsaturated fatty hydrocarbon, is carried out till the acid exerts little or no further action, but, from the behaviour of the paraffin oil from brown coal tar described above, it will be seen that these latter oils cannot be rectified in this manner.

The author does not treat of oils of specific gravity of less than .900, as these present no particular difficulty. An oil obtained on the large scale after separation of the paraffin and of sp. gr. .900 if distilled boils at 300°, but mostly boils at over 360°. The first of the distillate has a very strong smell; the later portion is milder. At the end of the distillation a yellow body very rich in sulphur comes over and clings to the wall of the condenser tube.

The smell and decomposition are not due to the atmosphere, but to the temperature of distillation, as the author obtained a similar result on distilling in a vacuum. Superheated steam introduced gives a better coloured product. The first distillate is citron coloured and the others strong yellow. In distilling the loss in specific gravity is not regular, but never exceeds 0.010, and more commonly is .005.

The author gives the results of a distillation of the heaviest oil, dark green and thick, of sp. gr. .945 at 14° R. On distilling by means of superheated steam with addition of 0.5 per cent. of caustic soda solution, the following fractions were obtained:—

	Kilos.	Specific Gravity at 14° R.
First runnings.....	224	0.881
Mixture .....	1,624	0.933
Red product I. ....	224	0.956
" " II. ....	140	0.968
" " III. ....	100	0.988
Total .....	2,312	0.935

The mixture on redistillation gave:—

	Specific Gravity at 14° R.	Viscosity (Engler) at 14° R.
Fraction I. ....	0.900	2.692
" II. ....	0.926	4.385
" III. ....	0.932	5.308
" IV. ....	0.935	5.770
" V. ....	0.937	6.923
" VI. ....	0.943	8.404
" VII. ....	0.956	11.535
Average.....	0.935	5.770

The oil, after treatment with sulphuric acid and caustic soda, can be bleached by exposure for one or two months to the direct rays of the sun. The oil must be dry and quite free from sulphonic acids. Blue or green glass is best for the bleaching bottles, yellow or dark-coloured glass is useless. Broad and shallow vessels are best for bleaching, glass carboys are also used. The shape is of considerable importance. The place should also be carefully chosen, so as to be moderately warm (20°—25°) and in a dry place and free from dust, and so that the direct rays of the sun fall upon the bleachers. Bleaching is much more rapid in the rays of the summer sun than in winter.

*The Refining Process.*—Of distillation in a vacuum the author's experience does not extend beyond the laboratory. Distillation with the aid of exhaust or superheated steam he regards as a questionable advantage, as it is difficult to separate the water condensed with the oil. He has not had experience of conversion of crystalline into amorphous

paraffin by distillation without steam. The process of distillation is valuable, indirectly, in refining as a means of separating the varieties of oil and fitting them for fresh acid treatment.

The acid treatment is important. Acid of 66° B. or fuming acid may be used. Of the former, 4 per cent. is the most which should be used at one treatment. The oil must be free from water, and the temperature should not exceed 20° or be below 10°. Agitation is best performed according to the Scotch method, viz., using an air blast.

The treatment of the partly refined yet dark non-transparent oil is accomplished by treatment with the requisite quantity of caustic soda, and distilling. The distillate after being cooled below 20° is agitated for 15 minutes with 3 per cent. of acid of 66° B. Care must be taken that the air blast is dry.

After settling an hour the acid tar has mostly subsided, and the oil is then treated with clay. Rich, extremely finely-ground potter's earth, free from water and organic matter, possesses in the highest degree the property of collecting and precipitating the black acid tar suspended in the oil. Poor clay is useless. The process is best done as follows: The separated tar being run off, the air blast is turned on, and 1 per cent. of potter's earth is scattered on the oil. After 15 minutes it is allowed to settle for an hour, and more earth, if required, added till the oil is clear.

The oil should be tested by smelling if free from sulphurous acid, and by agitation of a small portion with caustic soda. The oil is then treated with 1 to 2 per cent. of strong caustic soda solution warmed to 40°–60° and allowed to stand till clear, which takes, as a rule, 24 hours.

The acid process can then be repeated. For the second treatment 4 per cent. of sulphuric acid is used. The oil, after being treated with 3 per cent. of the earth, is then run to a tank and washed. The finished oil should be clear, yellow, and transparent.

Though the greater part of the sulphonic acids separate, some are left dissolved in the oil and form a milky emulsion on agitation with water, and if not removed decompose, giving an oil which cannot be bleached. They are removed by washing the oil with successive amounts of water and direct steam until the water is no longer milky. The oil can be recovered from this milky emulsion, but it is of very inferior quality. The oil is treated after the water is run off with 1–2 per cent. of caustic soda lye, settled, and bleached.

Oil which gives a strong emulsion and thus is darkened in colour by the long boiling, may receive a last treatment with 2 per cent. of fuming sulphuric acid for 10 minutes, settling, and treating with 2 per cent. of potter's earth till the oil is clear, and then transferring to a clean air-agitator and agitating with 1–2 per cent. of finely-powdered sodium carbonate until the smell of sulphurous acid disappears, the colour becomes citron yellow and strong frothing occurs. Two hours is the longest required for this neutralising. The oil is then settled and bleached.

This latter plan of using powdered alkali is the cheapest.

Excess of treatment with acid must be avoided or the oil will not bleach.

For storing oil, glass or lead vessels are best. Iron tends to colour the oil. In wooden casks the oil also darkens.

—D. A. S.

#### On Paraffin. B. Pawlewski. Ber. 23, 327–329.

THE paraffin employed for the purpose of this research was white ozokerite as found in commerce. It had a density of 0.917, melted at 64–65°, and solidified at 61°–63°. Analysis gave 84.86 per cent. of carbon and 15.02 per cent. of hydrogen. The following table gives the solubility in 100 parts of solvent at 18°–22°:—

	Per Cent.
Formic acid .....	0.013
Glacial acetic acid .....	0.060
Benzene (commercial) .....	1.990
Xylene (commercial) .....	4.000
Chloroform .....	2.420

The author has determined the freezing points of paraffin in glacial acetic acid, benzene, and paraxylene according to Raoult's method, and from the results which are tabulated in the original paper the following conclusions are drawn:—(1.) The maximum molecular weight of paraffin is represented by formulae ranging from  $C_{25}H_{50}$  to  $C_{27}H_{56}$ . (2.) In dilute solutions (not saturated) of benzene and paraxylene, paraffin shows at least twice this quantity, whilst (3.) in solutions which approximate saturation the maximum is probably represented by formulae ranging from  $(C_{25}H_{50})_4$  to  $(C_{27}H_{56})_4$ . From the properties exhibited by paraffin in various solvents it is inferred that it must be regarded as a colloidal substance, although with acetic acid it behaves like a crystalloid.—D. B.

#### PATENTS.

*Improvements in Coke Ovens, and in Methods of and Apparatus for Collecting and Utilising the Products of Combustion from such Coke Ovens.* A. M. Chambers; Thorncliffe, and T. Smith, Chapeltown. Eng. Pat. 7424, May 3, 1889. 8d.

AN improvement on the plant previously described in Eng. Pat. 7358 of 1885 (this Journal, 1886, 375.), by which the quality of the coke is improved, the coke obtained in larger pieces, and the products arising from the coking of the coal are more thoroughly and effectively collected and utilised.

The improvement consists in making an opening in the top of the coke oven so that the products of carbonisation are taken partly at the bottom and partly at the top; a more uniform heat is thus produced throughout the whole mass of the coal than is obtained by any other method of coking, and the whole of the volatile products have not to be forced through the coking coal.—F. S. K.

*Improvements in and Connected with Retorts for Distilling Shale or other Oil-yielding Minerals.* J. Armour, Edinburgh, and H. Armour, East Brich. Eng. Pat. 7634, May 7, 1889. 8d.

THE retorts, which are vertical, are arranged as usual in two rows, the space between the outer walls being divided by transverse partition walls so as to divide the retorts into sets of four or other convenient number. The distilling parts of the retorts are constructed entirely of firebrick or similar refractory material, and are heated by means of horizontal flues formed round them and communicating each with the next above it in a manner to cause the heating gases to pass completely through each horizontal flue in succession. At the tops of the retorts there are iron casings which serve as hoppers, the vaporised oil and other products being withdrawn through a pipe formed on or fixed to the bottom of each casing. The top casings serve for drying, and to some extent heating the minerals freshly charged into them at suitable intervals; and they are heated by a mixture of the heating gases from all the retort flues in a bench or from those of two or more sets of four retorts, these gases acting in a kind of top oven or flue space through which they may be directed in various ways.—F. S. K.

*Process for the Treatment of Vegetable Fibres by Means of Acid, Neutral, and Alkaline Residues of Naphtha Manufacture, or Specially Prepared Substances Analogous to such Residues.* V. Schevelin, Balakhna, and P. Mindovsky, Moscow, Russia. Eng. Pat. 8106, May 15, 1889. 6d.

WHEN treating mineral oils, or the products obtained by distillation therefrom, with sulphuric acid, and after the removal of the mineral oil, dark-coloured, tar-like "acid residues" are obtained. The mineral oil, thus purified, is treated with alkali (generally caustic soda) whereby "soda residues" of various colours and consistency are obtained. The soda and acid residues (which were hitherto comparatively useless) can be employed for working fibrous plants, such as flax, hemp, and the like. The residues can either be employed as they are produced at the factories, or they are prepared by the following method:—The mineral oil

distillates or the mineral oil itself is mixed with 5 to 12 per cent. by weight of sulphuric acid at 15° to 35° C. during one-half to two hours. The mixture has to stand for not less than two hours. The mineral oil that floats on the top is then separated from the acid residues below, neutralised with alkali and heated to 70° or 80° C. It is then allowed to stand again, when the soda residue will separate. The mineral oil separated from the soda residue and heated to from 35° to 90° C. is again treated with 15 to 20 per cent. of sulphuric acid with an addition of from 1 to 3 per cent. of chromic acid (or the corresponding quantity of potassium bichromate with sulphuric acid). There is then again produced an acid residue, while the oil separated from the same is again neutralised by alkali and heated, again obtaining soda residue. If this alternate treatment with acid and then with alkali be repeated several times, the greater part of the mineral oil product can be converted into the acid and soda residues, which was not possible with the treatment generally used at the factories. All acid residues contain free acid which is removed by repeated washing with hot water, or by treating with steam and then neutralising by an alkali. One part of the neutralised acid residues and nine parts of water are stirred together at 25° to 35° C., the mixture is allowed to stand and the oil floating on the solution removed. The soda residues resulting from the treatment of kerosene and other mineral illuminating oils, are employed directly in an aqueous solution containing not more than 10 per cent. of the residues. If they contain unconverted mineral oil, they are first washed with warm or hot water.

The fibres are separated from the woody matter as follows:—The fibrous plants are boiled from one-half to three hours at 70° to 95° C. in an aqueous solution containing not more than 10 per cent. of the residues, the reaction of which is alkaline, but can afterwards be rendered acid by adding sulphur dioxide, in order to obtain a lighter colour for the fibres, if required. The fibres are passed through pressing rollers, washed and brought into the drying chamber. After drying, they are broken and scutched, and the finished fibre passed through rollers. To obtain white flax or hemp, the fibres, after having been treated with the above-named alkaline solution, are introduced into a solution consisting of 2 parts of chloride of lime, 1 part of soda, and 60 parts of water where they are left for two or three hours, and further treated as above described.—H. S.

#### IV.—COLOURING MATTERS AND DYES.

*On Colouring Matters of the Benzene Group.* K. Henmann and H. Rey. Ber. 22, 3001—3005.

THE benzenees, obtained by the action of benzyl trichloride on phenols, resemble to a certain extent the phthaleins, but they are very weak colouring matters and of no value for technical purposes. As, however, the dimethyl-*m*-amidophenol-phthalein (rhodamine) has been proved to be a valuable colouring matter, the corresponding benzenee was prepared and is also a beautiful colouring matter, similar in strength, shade and fastness to rhodamine. The authors call this class of colouring matter "*Rosamines*."

*Tetramethylrosamine* is obtained by the action of benzyl-trichloride (1 mol.) on dimethylamidophenol (2 mol.) at 50°—60° C. As the reaction is very violent it is advisable to add sand or benzene as a diluting agent. The temperature is kept at 60° C., and the reaction completed on the water-bath. Impurities are removed by steam and the colouring matter is dissolved in water containing hydrochloric acid, and then precipitated by common salt. Its formula is—

Its salts are soluble in water and alcohol with a beautiful bluish-red colour and yellowish-red fluorescence. They dye wool, silk and jute from a pink to a dark bluish-red. The colours on silk or jute exhibit strong fluorescence, which is increased by treatment with sulphuric acid. Zinc dust reduces the rosamines, and the solutions remain colourless on standing, even with access of air. Addition of caustic soda in most cases does not produce an immediate precipitate. A sodium salt of the benzene seems to be formed. Extraction of the alkaline solution with benzene and evaporation of the latter yielded a product of the formula  $\text{C}_{24}\text{H}_{21}\text{N}_2(\text{OH})_3$ . The authors further prepared *tetra-ethylrosamine* and *diphenylrosamine*. The former is bluer than the corresponding methyl compound, the latter is a violet colouring matter, insoluble in water.—A. L.

*On Weselsky's Resorcinol Colouring Matters.* R. Nietzki, A. Dietze, and H. Mäckler. Ber. 22, 3020—3039.

WESELSKY obtained, by the action of nitric acid containing nitrous acid, two remarkable bodies, diazoresorcinol and diazoresorfinol. A bromine derivative of the latter compound is used as a dyestuff and sold under the name of "Fluorescent Blue" (this Journal, 1888, 315—316; also 1885, 50—51). Brummer and Krämer worked and published on the same subject, and their results are altogether different from those obtained by the discoverer of these compounds.

The authors have broken up this research and propose to call diazoresorfinol "*resorfinol*," and diazoresorcinol "*resazurinol*."

*Resazurinol* was prepared according to Weselsky and Benedikt's method by adding to a solution of 10 parts of resorcinol in 500 parts of ether, eight parts of red fuming nitric acid, and allowing the mixture to stand for two days. The only deviation from this method was that of cooling the resorcinol solution to from —5° to —8° C., and that of diluting the nitric acid with ether. The yield of crystals was 75 per cent. of the quantity of resorcinol taken. The purification was performed in the following manner: The mixture of Resazurinol and Resorfinol was washed with water and then triturated with a warm concentrated solution of sodium carbonate. After some time the product solidified to a mass of crystals of sodium resazurate, whilst the salt of resorfinol remained in solution. After filtering, the crystals are dissolved in hot water and sufficient concentrated soda solution added, to induce crystallisation to set in. The crystals are treated in the same way until perfectly pure. Sodium resazurate crystallises in long green needles, soluble in hot water, with difficulty in soda or solution of salt. The formula of Resazurinol is  $\text{C}_{12}\text{H}_7\text{NO}_4$ . It has the character of a weak base, forming salts with concentrated acids. With alkalis it acts as a mono-basic acid. It is rapidly decomposed by caustic alkalis, ammonia escaping. The barium salt,  $(\text{C}_{12}\text{H}_6\text{NO}_4)_2\text{Ba}$ , is with difficulty soluble in water.

*Resazurinol-ethylether* was prepared by treating silver resazurate with ethyl-iodide. Dark red needles are formed, melting at 215° C.

*Monacetylresazurinol* is obtained by heating sodium resazurate with dehydrated sodium acetate and acetic anhydride on the water-bath. Ruby-red needles, soluble in alcohol, and melting at 222° C. If the mixture of resazurin sodium acetate and acetic anhydride be boiled longer, acetylresorfinol is formed, and after very prolonged and energetic treatment products are obtained which cannot be crystallised.

*Tetrabromoresazurinol*, obtained as a blue colouring matter by Weselsky and Benedikt by the action of bromine on Resazurin. The authors prepared it by acidulating a mixture of sodium resazurate and an alkaline bromine solution. The sodium salt has the formula  $\text{C}_{12}\text{H}_2\text{Br}_4\text{NO}_4\text{Na} + 2\text{H}_2\text{O}$ . Reducing agents convert this non-fluorescent body into the fluorescent tetrabromoresorfinol. By heating resazurinol and acetyl chloride together an acetyl compound, containing chlorine, is formed, probably a mixture of different products.

*Resorufinol* is obtained from *Resazurinol* by various methods. For example, by heating the latter with concentrated sulphuric acid to  $210^{\circ}\text{C}$ .; by heating it with a bisulphite solution, or by reducing it with zinc dust or iron, and oxidising afterwards the product. It is distinguished by its beautiful pink colour and the magnificent fluorescence of its alkaline solution. *Resazurinol* and *resorufinol* yield the same reduction product, which, however, when re-oxidised in an alkaline solution, forms only *Resorufinol*. The analysis of the purified body agrees with the formula  $\text{C}_{12}\text{H}_6\text{N}_2\text{O}_3$ , a reduction product of *resazurinol*.

*Resorufinol-ethylether*, obtained by heating silver *resorufinate* with ethyl iodide and alcohol. It crystallises in orange needles, melting at  $225^{\circ}\text{C}$ . The formula is  $\text{C}_{12}\text{H}_{10}\text{N}_2\text{O}_3 \cdot \text{C}_2\text{H}_5$ . Krämer describes a product, which he calls "azoresorufinol-dimethylether," and which was obtained by heating *resorcinol* and *p*-nitrotoluene with concentrated sulphuric acid. This body is, however, identical with *resorufinol*, only of a not very pure character.

*Acetylresorufinol*,  $\text{C}_{12}\text{H}_6\text{N}_2\text{O}_3 \cdot \text{C}_2\text{H}_3\text{O}$ , prepared from *resorufinol* acetic anhydride and sodium acetate, crystallises from alcohol in long needles, melting at  $223^{\circ}\text{C}$ .

*Fluorescent Blue* is prepared according to Bindschedler and Busch's patent, by treating *Resorufinol* with bromine. The authors obtained it in the same way as *Tetrabromoresazurinol*. The sodium salt,  $\text{C}_{12}\text{H}_2\text{Br}_4\text{N}_2\text{O}_3\text{Na} + 2\text{H}_2\text{O}$ , crystallises in beautiful green needles.

*Hydroresorufinol* is formed when either *Resorufinol* or *Resazurinol* are heated with an acid stannous chloride solution. The compound crystallises in flat colourless needles, which, on dissolving in carbonates, reproduce *Resorufinol* on contact with air. It is doubtless the hydrochloride of a leuco base of *Resorufinol*. The body being heated for some time with sodium acetate and acetic anhydride forms the triacetyl derivative of a compound having two hydrogen atoms more than *Resorufinol*. It melts at  $216^{\circ}\text{C}$ ., and its formula is  $\text{C}_{12}\text{H}_6\text{N}_2\text{O}_3(\text{C}_2\text{H}_3\text{O})_3$ . Its molecular weight was estimated by Raoult's method and found to be 282, 306, 279, 303, whilst the formula demands 341. On distillation with zinc dust abundant quantities of diphenylamine are formed. On suspending *Resorufinol* in a strongly hydrochloric acid solution of hydroresorufinol, a hydrochloride crystallising in fine copper-coloured needles is formed, soluble in alcohol with a greenish-blue colour.

*Constitution of Resorufinol and Resazurinol*.—The *Resorufinol* contains three oxygen atoms, one of them as a hydroxyl group; the nitrogen is in form of trivalent nitrogen. Of all the methods of preparation the one which is based on the action of nitrosoresorcinol on *resorcinol* is the most interesting. According to Witt's, Meldola's, and Nietzi's researches, nitroso bodies act on amines or phenols in such a manner that the nitrogen of the nitroso group is joined to the benzene nucleus of the other molecule, oxygen being eliminated; in the para-position to the hydroxy- or amine-group. Thus indamines and indophenols are prepared. If molecular quantities of nitroso-resorcinol and *resorcinol* be dissolved in cold concentrated sulphuric acid, the mixture is coloured blue and dissolves in alkalis with a blue-violet colour. This cannot therefore be *Resorufinol*, which dissolves in concentrated sulphuric acid with a red colour. After prolonged heating to  $100^{\circ}\text{C}$ ., this body is converted into *Resorufinol*. It is, perhaps, the true indophenol of *resorcinol*—

which, under the influence of sulphuric acid, changes into—

*Resorufinol* is therefore to be considered as—

which, on reduction, yields—

hydroresorufinol or di-hydroxyphenoxazine. Further proofs for this theory are adduced through the medium of different new methods for preparing this body. It was obtained by the action of nitrosophenol on *resorcinol*, by nitrosoresorcinol on phenol, by oxidising *p*-amidophenol and *resorcinol* in sulphuric acid solution with manganese dioxide, &c. Amidoresorcinol and orthocresol yield an analogous body, but para-cresol does not. This confirms the author's hypothesis.

*Resazurinol* is possibly—

A. L.

#### On the Formation of Azines from Orthodiamines and Polyamines. R. Nietzki. Ber. 22, 3039—3040.

In a former treatise the author described the formation of tetramidophenazine from the symmetrical tetramidobenzene. Müller afterwards found that the unsymmetrical triamidobenzene yields in a similar way triamidophenazine. Fischer and Hepp proved the oxidation product of orthophenylenediamine to be a diamidophenazine, and Kehrman obtained from *o*-diamido-*p*-toluic acid—

a diamido-azine, which must have the formula—

From these facts the author concludes that the same law which governs the action between paradiamines and monamines with a free para-position applies also to the orthodiamines, with the only difference, however, that in the case of ortho compounds the juncture is a double one. With Tetramidobenzene, the action is as follows:—

With Triamidobenzene—

and with *o*-Diamidobenzene—

Meta-para-tolylenediamine,  $\text{C}_6\text{H}_3(\text{NH}_2)(\text{NH}_2)(\text{CH}_3)$  [1:2:4] cannot form an azine, as the para-position is not free.

—A. L.

On some Azo dyes from Naphthoresorcinol. St. v. Kostanecki. Ber. 22, 3163—3168.

ZINKE and Bindewald obtained by the action of phenylhydrazine on  $\alpha$ -naphthoquinone a product identical with phenylazo- $\alpha$ -naphthol. If phenylhydrazine acts in a similar way on hydroxy- $\alpha$ -naphthoquinone, phenylazonaphthoresorcinol ought to be formed. Zinke and Thelen, however, came to the conclusion that not this product, but in consequence of intramolecular changes,—

was formed.

The authors repeated Zinke's experiments and found the body to be phenylazonaphthoresorcinol, and not the hydrazide, which Zinke believed it to be.

The compound was prepared according to Zinke's method. It melted, however, at 218—220° C., and not at 228—230° C. as Zinke states.

*Nitrosophenylazonaphthoresorcinol* is prepared by pouring an alkaline solution of phenylazonaphthoresorcinol and sodium nitrite into dilute hydrochloric acid. A brown floccular precipitate is formed, crystallising from dilute acetic acid in small bright brownish-red plates, soluble with difficulty in hot water and alcohol, easily in glacial acetic acid, and decomposing at 175° C. It is insoluble in alkalis, but soluble in concentrated sulphuric acid with a dark green colour. The compound dyes mordanted fibre, much more feebly, however, than nitrosophenylazoresorcinol.

*Reduction of Nitrosophenylazonaphthoresorcinol*.—On reduction with tin and hydrochloric acid amidonaphthalenic acid—

and aniline are formed.

#### *Phenyldisazonaphthoresorcinol*—

was obtained by acting with diazobenzene chloride on sodium phenylazonaphthoresorcinol. It forms, recrystallised from a mixture of chloroform and alcohol, long red needles, insoluble in caustic alkalis, decomposing whilst melting, at 225° C. On reduction, the same products are formed as from the nitroso-compound.

#### *Diacetylphenylazonaphthoresorcinol*—

If phenylazonaphthoresorcinol be boiled for some minutes with acetic anhydride and dehydrated sodium acetate, a diacetyl-compound is formed, crystallising from dilute alcohol in needles, melting at 122°—123° C.—A. L.

#### *On $\alpha$ -Naphthylamine and $\alpha$ -Naphthol- $\epsilon$ -disulphonic Acid.*

A. Bernthsen. Ber. 22, 3327—3335

$\alpha$ -NAPHTHYLAMINE- $\epsilon$ -DISULPHONIC acid is prepared, according to the patent of the Berlin "Actien Gesellschaft für Anilin fabrikation," by treating naphthalene with fuming sulphuric acid at the ordinary temperature. On nitrification of the sulphonic acids two isomeric nitro-, and from these by reduction two amidonaphthalene sulphonic acids are formed, which can be separated by crystallisation of their neutral sodium salts. The naphthylamine sulphonic acid which forms the more difficultly soluble sodium salt, is identical with the one patented by Schöllkopf. From the mother-liquor the acid sodium salt of the isomeric  $\epsilon$ -compound is precipitated by hydrochloric acid. Ewer and Pick

have applied for a patent to protect the preparation of a naphthylamine- $\alpha$ - $\beta$ -disulphonic acid, obtained from naphthalene- $\alpha$ - $\beta$ -disulphonic acid, which is identical with  $\alpha$ -naphthylamine- $\epsilon$ -disulphonic acid.

A third method forms the subject of an application of the Badische Anilin und Soda Fabrik. One part of naphthalene is converted into its disulphonic acid by heating it with five times its weight of concentrated sulphuric acid to from 80°—100° C., or by treating it first with ordinary concentrated acid at 90° C., and then with fuming acid at a temperature not higher than 120° C. The disulphonic acid is nitrated, and precipitated by common salt, and then reduced. The naphthylaminedisulphonic acid is then precipitated as acid sodium salt from its neutral salt solution by acids. It is identical with  $\alpha$ -naphthylamine- $\epsilon$ -disulphonic acid.

#### *The acid sodium salt—*

forms needles or thin prisms.

#### *The neutral sodium salt—*

is very soluble in water and crystallises in long needles or prisms.

The *neutral barium salt* crystallises either with 3 mols. of water in light yellow needles, or with 4 mols. of water in colourless flat needles.

The *acid barium salt* forms microscopic needles containing 2½ mols. of water. The free acid crystallises with 3 mols. of water, and forms on treatment with nitrogen trioxide a very soluble diazo-compound acid, whilst on treatment with nitrites and sulphuric acid a difficultly-soluble diazo-sodium salt is obtained. If this diazo-compound be boiled with water containing sulphuric acid two very different bodies may, according to subsequent operations, be produced, viz., naphthol- $\epsilon$ -disulphonic acid and its "sultone" (Erdmann).

$\alpha$ -Naphthol- $\epsilon$ -disulphonic Acid is obtained by mixing the diazo-compound with water and boiling it with addition of some sulphuric acid. On treatment with lime and filtration from gypsum, a calcium salt is obtained, which is converted into the sodium salt by treatment with sodium carbonate. Long colourless prisms of the formula—

are formed, easily soluble in water. With diazo-compounds colouring matters are formed. The combination with diazobenzene is an orange yellow; with diazoxylene a scarlet; with  $\alpha$ -naphthylamine a red; and with benzidine a violet colour.

*Naphtholsultone Sulphonic Acid* ("Zeta-naphtholdisulphonic acid.")—If diazonaphthalenedisulphonic acid be boiled with water and sulphuric acid until the evolution of nitrogen is ended, and if the liquid be then rapidly cooled and not treated with calcium hydroxide, a crop of long fine needles is formed. The substance can be obtained pure by recrystallisation from hot water. Analysis gives figures for  $C_{10}H_5SO_3(SO_3Na) + 3 H_2O$ . Its constitution is—

and it must be considered as an intra-molecular anhydride; alkalis and carbonates convert it into a disulphonic acid. The author considers the compound to be—

$\epsilon$ -Naphtholsultone sulphonic acid.

It forms azo colouring matters the same as those obtained from naphtholdisulphonic acid.

*Naphtholsulphamidesulphonic acid* is obtained by dissolving the sultone sulphonic acid in concentrated ammonia, and on addition of hydrochloric acid to the cold solution

the sodium salt of the new compound crystallises out in long needles. Its formula is  $C_{10}H_8NS_2O_6Na + H_2O$ , and its constitution—

It forms colouring matters with diazo-compounds which are bluer than those obtained from the disulphonic acid.

—A. L.

*On Nitrotoluidine Sulphonic Acids.* R. Nietzki and Pollini. Ber. **23**, 138—140.

ORTHOTOLUIDINE sulphonic acid, obtained by treating orthotoluidine with the calculated amount of sulphuric acid, was acetylated by heating its sodium salt with anhydrous acetic acid, and the acetyl compound was then nitrated in sulphuric acid solution. The temperature was kept below 5° C. The potash salt of the nitrotoluidine sulphonic acid was precipitated from its concentrated aqueous solution in orange needles by addition of an excess of caustic potash. The free sulphonic acid is precipitated from concentrated solutions of the potash salt by mineral acids.

Another way to prepare the same compound is to treat *o*-acet-toluide with three times its weight of fuming sulphuric acid containing 15—20 per cent. of anhydrous sulphuric acid, on the water-bath, until completely soluble in alkalis, and to nitrate this sulphonic acid. The sulfo-group was eliminated by heating this body with dilute sulphuric acid in a sealed tube for three hours at 170°—180° C. On addition of ammonia a volatile base was obtained, which was carried over with steam. This is thus proved to be an ortho-compound, and has the formula—

The corresponding sulphonic acid has the formula—

This latter body forms a difficultly soluble diazo-compound, which combines with phenols producing colouring matters. By careful reduction with stannous chloride a nitrohydrazine can be prepared. If the mixture of the nitrotoluidine sulphonic acid, stannous chloride and hydrochloric acid be heated, a diamidotoluene sulphonic acid is obtained, which crystallises from water in colourless needles. This acid is an ortho-diamido-compound forming azines with ortho-diketones as phenanthrenequinone or croconic acid. The potassium salt of the condensation product with the latter compound crystallises in dark greenish-black needles of the formula—

The para-toluidine sulphonic acids—

and

yield on analogous treatment as the above described ortho-compound, nitro-products which contain the nitro group in the ortho position with respect to the amido group. Both acids yield this same nitrotoluidine,—

melting at 114° C., and their constitution, therefore, is—

and

By reduction two diamido-compounds are obtained analogous in their reactions to the above described isomeric compound.—A. L.

*Triphenyldiazine as an Oxidation Product of Ortho-amidophenol.* P. Seidel. Ber. **23**, 182—189.

G. FISCHER obtained by oxidising an aqueous solution of ortho-amidophenol with red prussiate of potash a brown amorphous colouring matter and a body subliming in garnet-red crystals of the formula  $C_{21}H_{16}N_2O_2$ . The author improved the method of preparation by boiling a solution of ortho-amidophenol hydrochloride in 30—40 times its weight of water in a flask with reversed condenser, passing at the same time a current of air through the solution. The sole method of purification is to sublime the crude product. The analysis indicated the formula  $C_{18}H_{16}N_2O_2$ , and not, as Fischer found,  $C_{21}H_{16}N_2O_2$ . The formation of this body takes place according to the equation—

The colouring matter is nearly insoluble in water, alcohol, ether, acetone, carbon bisulphide, pyridine, benzene, &c., but exhibits in all these solvents, with the exception of water, a beautiful green fluorescence. Xylene, nitrobenzene, aniline, azobenzene, naphthalene, &c., are the best solvents for crystallising it from, and it is obtained in dark red crystals from these solvents.

This colouring matter begins to sublime at 250° C., and forms at 300° C. a beautiful green vapour. Concentrated aqueous or alcoholic solutions of potash or soda are without action on this body. Anhydrous acetic acid does not produce an acetyl compound. Concentrated hydriodic acid reproduces at 170° C. ortho-amidophenol. Chromic acid in acetic acid solution even on boiling does not act upon it. Chlorine does not change it, but bromine forms substitution products. On treatment with sulphuric acid a sulphonic acid is obtained, forming alkaline salts soluble with difficulty in water. Nitric acid yields a mono-nitro-product, which yields an indigo blue colouration with concentrated sulphuric and hydrochloric acid. On reduction, an amido-compound is obtained, forming blue salts little soluble in water.

Hydrochloric acid forms a salt crystallising in dark green needles of the formula  $C_{18}H_{16}N_2O_2 \cdot 2 HCl$ .

The *Leuco-compound*,  $C_{18}H_{16}N_2O_2$ , is obtained by reducing the colouring matter with phenylhydrazine diluted with xylene. The reduction begins at 120° C., phenylhydrazine being decomposed into benzene, two nitrogen atoms and two hydrogen atoms, which are taken up by the colouring matter. The leuco-base is more easily soluble in the various solvents than the colouring matter. It can be crystallised from pyridine, to which some phenylhydrazine has to be added to prevent oxidation. It forms colourless plates, and the substance when heated to 250°—300° C. dissociates into hydrogen and the original colouring matter. On boiling the leuco-base with anhydrous glacial acetic acid a diacetyl compound,  $C_{18}H_{16}(C_2H_3O)_2N_2O_2$ , is formed, melting at 295° C. and crystallising in colourless plates. According to the author's views the formula of the colouring matter is—

It consequently contains the chromophoric group—

The colouring matter is therefore named *Triphenyldiazine*.

—A. L.

*On some Derivatives of Nitro-β-Naphthoquinone.* R. Zärtling. Ber. **23**, 175—180.

*Nitronaphthophenazine* was prepared by mixing a solution of 2 grms. of nitro-β-naphthoquinone in 40 cc. of glacial acetic acid with a solution of 1.8 grms. of *o*-phenylenediamine and 2.7 grms. of sodium acetate in 10 cc. of acetic acid of 50 per cent. strength. The colour of the mixture changes to orange, and a precipitate of a powdery nature

falls down. To complete the reaction the mixture was heated for some time on the water-bath. The dirty yellow substance formed was washed with glacial acetic acid and then recrystallised from a mixture of 4 parts of phenol and 20 parts of glacial acetic acid. It melts at  $221^{\circ}$ — $222^{\circ}$  C., forms prisms of greenish-yellow colour, is with difficulty soluble in alcohol, benzene, ether, and insoluble in petroleum spirit. Its formula is  $C_{10}H_5.NO_2.N_2.C_6H_4$ .

*Amidonaphthophenazine* was obtained by reducing 2 grms. of the nitro-compound with 25 cc. of alcoholic ammonium sulphide at  $100^{\circ}$  C. The yellow body is then changed into an orange one. It crystallises from aniline in small dark brownish-red crystals, which on being ground form a cherry-red powder, melting at  $191^{\circ}$  C. It is with difficulty soluble in alcohol and ether, but more easily in benzene. Its dark red ethereal solution is decolourised by hydrochloric acid, a hydrochloride being formed. *This is the first instance of a Eurlodine which forms colourless salts, whilst the base is itself coloured.* Its formula is—

Experiments with the object of producing an azonium base from orthophenylnaphthylenediamine and nitro- $\beta$ -naphthoquinone were unsuccessful.

*Nitro- $\beta$ -hydroquinone* was obtained from the quinone by reduction with stannous acid. Groves' method of reducing it with stannous chloride and hydrochloric acid gives, however, far better yields. It melts at  $159.5^{\circ}$  C., and dyes fibres mordanted with metallic oxides. It forms with iron mordants a yellowish-brown, with chrome mordants a pale indigo blue, and with aluminium mordants a red. The colours are, however, not fast to soap.

Phenylhydrazine reduces nitro- $\beta$ -naphthoquinone to hydroquinone, phenylhydrazine forming benzene, azo-benzene, aniline and nitrogen.

Hydroxylamine hydrochloride forms an addition product with the quinone  $C_{10}H_5.O_2.NO_2.NH_2.OH$ , melting at  $140^{\circ}$ — $141^{\circ}$  C., with evolution of gas, to a dark red liquid. It is very insoluble, and is decomposed on boiling with acetic acid or other solvents, the quinone being reduced to the hydroquinone.—A. L.

*On Alicyclic  $\beta$ -Tetrahydronaphthol and Secondary Ring Alcohols.* E. Bamberger and W. Lödter. Ber. **23**, 197—213.

The two naphthylamines form by the action of sodium and boiling amyl alcohol, bodies containing four atoms of hydrogen more than the original compounds. If they enter the substituted ring the resulting base belongs to the aliphatic series; if they enter the other ring they belong to the aromatic series. Alpha-naphthol is converted by the same treatment into a body of the formula—

The resulting compound is a true phenol, soluble in alkali, and forming colouring matters with diazo-compounds.  $\beta$ -naphthol forms two compounds richer by four hydrogen atoms—

No. I. differs from No. II. as a phenol from an alcohol. No. I. has all the properties of  $\beta$ -naphthol; No. II. presents no points of resemblance to it. It is a thick oil, insoluble in alkalis and not capable of forming colouring matters with diazo-compounds. It shows a great similarity in modes of reaction to menthol and borneol. It was prepared by

treating a boiling solution of 10 grms. of  $\beta$ -naphthol in 200 grms. of amyl alcohol with 20 grms. of sodium, which was gradually added in portions of 4—5 grms. The blue colour of the mixture soon changed to yellow. It is boiled until all sodium is dissolved, then it is poured hot into water. The reddish-brown layer of amyl alcohol is washed several times with caustic soda, then with water, and finally with dilute hydrochloric acid. It is then distilled under the ordinary pressure until the thermometer indicates  $150^{\circ}$ — $160^{\circ}$  C. The distillation is continued in vacuo. Two fractions are obtained, one at  $150$ — $205^{\circ}$  C., the other at  $210^{\circ}$ — $290^{\circ}$  C.

In the flask there remains a pitchy residue, not distilling at  $300^{\circ}$  C. The first fraction contains the new compound. It is purified by passing steam through a mixture of the first fraction with caustic soda of 1.5 per cent. strength. The last traces of aromatic hydronaphthol are removed by diazobenzene sulphonic acid, which does not act on the alicyclic compounds. It is then dissolved in ether and it remains after evaporating the solvent as a colourless oil boiling under a pressure of 716 mm. at  $264^{\circ}$  C. It is with difficulty soluble in water, easily in alcohol, ether, benzene, carbon bisulphide, and chloroform, but insoluble in the alkalis. The authors describe several derivatives of this compound.

*Alicyclic  $\beta$ -tetrahydronaphthylcarbonate of sodium*,  $C_{10}H_{11}.O.CO_2Na$ . This is a very unstable compound, and is obtained by passing carbonic acid through the sodium salt of the alcohol.

*Dihydronaphthalene*,  $C_{10}H_{10}$ , obtained by the action of solid potassium hydrate on the alcohol.

*Alicyclic acetyl- $\beta$ -tetrahydronaphthol*,  $C_{10}H_{11}.O.CO.CH_3$ . This is an oil boiling under a pressure of 34 mm. at  $169^{\circ}$  C.

*Alicyclic benzoyl- $\beta$ -tetrahydronaphthol*—

white crystals melting at  $62$ — $63^{\circ}$  C., and boiling under a pressure of 40 mm. at  $254$ — $255^{\circ}$  C.

*Alicyclic  $\beta$ -tetrahydronaphthylchloride*,  $C_{10}H_{11}Cl$ , obtained by the action of hydrochloric acid on the alcohol, could not be purified. Other compounds of less interest are described. —A. L.

*On Aromatic  $\alpha$ -Tetrahydronaphthol.* E. Bamberger and F. Bortt. Ber. **23**, 215—218.

The hydration of  $\alpha$ -naphthol proceeds analogously to that of  $\alpha$ -naphthylamine, the four hydrogen atoms entering into the non-substituted ring. The experiment was carried out in the ordinary way by treating 10 grms. of  $\alpha$ -naphthol with 20 grms. of sodium. The liquid turns, finally, light yellow. The  $\alpha$ -tetrahydronaphthol boils after purification at  $264.5^{\circ}$ — $265.5^{\circ}$  C., it solidifies to white plates, similar in appearance to naphthalene, and melting at  $68.5^{\circ}$ — $69^{\circ}$  C. It has the character of a phenol and forms azo-colouring matters with diazo-compounds.

*Phenylazo- $\alpha$ -tetrahydronaphthol*,  $C_6H_5.N_2.C_{10}H_{10}.OH$ , is obtained in the usual way from diazo-benzene chloride and an alkaline solution of the phenol. Green plates with a metallic lustre, insoluble in water, with difficulty soluble in benzene, soluble in glacial acetic acid, and easily soluble in chloroform.

*Aromatic  $\alpha$ -tetrahydronaphthol-azo-benzene sulphonic acid*,  $(SO_3H)C_6H_4.N_2.C_{10}H_{10}.OH$ , is obtained from diazo-benzene sulphonic acid and  $\alpha$ -tetrahydronaphthol. The free acid forms scarlet-red leaves.

*Aromatic tetrahydro- $\alpha$ -naphthylethylether*,  $C_{10}H_{11}.OC_2H_5$ , boils at  $259^{\circ}$  C. under a pressure of 705 mm.—A. L.

*Hydrogenised Naphthylamines.* E. Bamberger. Ber. **23**, 291—292.

AMONG the hydrated naphthalene bases two are distinguished by containing asymmetrical carbon atoms, viz., the alicyclic  $\alpha$ -tetrahydronaphthylamine—

and the alicyclic 1, 5-tetrahydronaphthylendiamine—

These compounds are optically inactive. The author, however, succeeded in separating the first base into two active compounds, the one turning the ray of polarised light to the right, the other to the left. The separation was accomplished by preparing the acid tartrates, the salt turning the rays of polarised light to the left crystallising, whilst the remaining syrup contained the other base.—A. L.

*On the Hydroxy-azo- (Orxazo-), and Amido-azo Compounds.* H. Goldschmidt and Y. Rosell. Ber. **23**, 487—508.

OXYAZO COMPOUNDS were considered, until a few years ago as hydroxy compounds of azo bodies. Since 1884 a series of reactions has been discovered, which render it possible to consider these products as quinone derivatives, and to explain, for example, the constitution of oxy-azo-benzene by the formula—

the phenylhydrazone of quinone. Zincke's synthesis of benzene-azo- $\alpha$ -naphthol by the action of phenylhydrazine on  $\alpha$ -naphthoquinone offers valuable support to this theory.

Ortho-oxy-azo compounds are converted by carbon bisulphide into anhydro compounds of ortho-amido-phenols. Benzene-azo- $\beta$ -naphthol forms, for instance—

Thiocarbanilidonaphthol.

Carbanilamidonaphthol.

The hydrazones of orthoquinones behave in an analogous way. Phenanthrenequinonephenylhydrazone—

yields on heating with carbon bisulphide—

Thiocarbanilidophenanthrol.

Carbanilamidophenanthrol.

*Oxy-azo-benzene and Phenylecyanate.*—Oxy-azo-benzene must be either—

Phenylecyanate would act on this body in either case, and the resulting product would be either—

If oxy-azo-benzene and phenylecyanate be heated with addition of benzene to 170° C., a body is produced, which, when recrystallised from benzene, forms orange-yellow needles, soluble in alcohol and ether, insoluble in alkalis, and melting at 149° C. Its formula is  $\text{C}_{10}\text{H}_{13}\text{N}_3\text{O}_2$ . On heating this body with alcoholic potash, oxy-azo-benzene, aniline and carbonic acid are formed. If the first formula be correct, the product could be considered as a phenyl-carbanido-ether, whilst formula No. II. represents it as a kind of urea. The former bodies are easily acted upon by caustic alkalis, the latter proving far more stable under the action of these agents. The authors prepared a complicated member of the ureas by the action of phenylecyanate on hydrazobenzene in order to study the properties of a product which leaves no doubt as to constitution. By heating 2 mols. of phenylecyanate with 1 mol. of hydrazobenzene, in presence of a little benzene at 150° C., a greyish-blue amorphous mass was obtained, insoluble in all solvents, and melting at 218—220° C. Analysis proved that this body was the expected dicarbanilidohydrazobenzene, formed according to the equation—

This body is extremely stable towards alcoholic potash, not suffering change even when heated to 150° C. Only at 200° C. it is converted into aniline, carbonic acid and benzdinehydrochloride.

This indicates that the oxy-azo-benzene must be represented as a phenol, i.e., as *hydroxyazobenzene*.

*Reduction of Carbanilido-oxy-azobenzene:* Carbanilido-oxyhydrazobenzene,  $\text{C}_{19}\text{H}_{17}\text{N}_3\text{O}_2$ .—If the reduction be performed with stannous chloride and hydrochloric acid, only aniline and paramidophenol are formed. If, however, zinc dust and glacial acetic acid are the reducing agents used, a colourless body, crystallising from benzene in needles is obtained, melting at 155° C. This is carbanilido-oxyhydrazobenzene. It is readily reoxidised to the original body. Alcoholic potash liberates aniline, whilst at the same time hydroxyazobenzene is formed, probably by immediate oxidation or the intermediate oxyhydrazobenzene. According to theoretical speculations of the authors the constitution of—

*Hydroxyazobenzene* is  $\text{C}_6\text{H}_5\text{N}:\text{NC}_6\text{H}_4\text{OH}$ .

*Carbanilido-oxyazobenzene* is—

*Carbanilido-oxyhydrazobenzene* is—

*Hydroxyazobenzene and  $\alpha$ -Naphthylecyanate* act on each other in the same way as above described, forming  $\text{C}_6\text{H}_5\text{N}=\text{NC}_6\text{H}_4\cdot\text{OCONH}\cdot\text{C}_{10}\text{H}_7$ , melting at 149° C. On reduction with zinc dust and acetic acid the corresponding hydrazo compound  $\text{C}_6\text{H}_5\text{N}:\text{NHNH}\cdot\text{C}_6\text{H}_4\cdot\text{OCONH}\cdot\text{C}_{10}\text{H}_7$  is obtained, melting at 155° C.

Two molecules of phenylecyanate acting on 1 molecule of carbanilido-oxyhydrazobenzene form a white crystalline powder melting at 215—218° C., of the formula  $\text{C}_{20}\text{H}_{17}\text{N}_5\text{O}_4$ . On boiling with alcoholic potash, diphenyl urea, aniline, and some other products were obtained, which were not further examined.

An isomeride of carbanilido-oxyhydrazobenzene was obtained by heating the latter with benzaldehyde to 150° C. It forms colourless needles, nearly insoluble in benzene, soluble in alcohol, and melting at 218°—222° C. The same body is formed by heating a mixture of the hydrazo compound and benzene to 150° C. Its constitution is not yet definitely settled.

*Orthohydroxyazo Bodies and Phenylecyanate do not React on each other.*—Experiments with benzene-azo-para-cresol,  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{OH})\text{N}:\text{C}_6\text{H}_5$  [1:4:3], benzene-azo- $\beta$ -naphthol,  $\text{C}_{10}\text{H}_6(\text{OH})\text{N}:\text{C}_6\text{H}_5$ , were without result, however the conditions were varied. These bodies have probably to be considered as hydrazones.

Phenoldisazobenzene,  $C_6H_3(OH)(N_2C_6H_5)_2$  [1:2:4] and phenyleyanate react on each other if heated to  $170^\circ C.$ , forming a body crystallising from benzene in small yellow needles, which melt at  $133^\circ-135^\circ C.$  It is carbanilido-phenoldisazobenzene,  $C_{10}H_5.NHC_6H_5.O.C_6H_3(N_2C_6H_5)_2$ .

**Amido-azo-Compounds.**—Whilst there are no reasons to alter the formula representing the constitution of the para-compound, a series of observations on ortho-amido-azo-compounds has been made, which seem to indicate that the present interpretation of these bodies is deficient. According to Zincke they have to be considered as imidohydrazones; the benzene-azo- $\beta$ -naphthylamine, for instance, being capable of representation as either—

Carbodi-imido bodies form addition compounds with the phenyl amides, whereas such a reaction is not possible with imido derivatives. Acting with phenyleyanate on amido-azo-benzene the authors obtained a golden yellow compound, soluble in alcohol, nearly insoluble in benzene, and melting at  $216^\circ C.$  The substance was carbanilido-amido-azo-benzene,  $C_{10}H_{16}N_4O$ . Further experiments proved its constitution to be—

Benzene-azo-diphenyl urea. Amido-azo-benzene, therefore must be  $C_6H_5.N_2C_6H_4NH_2$ .

**Ortho-Amido-azo-toluene** must be either—

Phenyleyanate acts on its benzene solution at ordinary temperatures. The brownish-yellow precipitate, recrystallised from hot alcohol forms golden-yellow pointed needles, melting at  $219^\circ C.$ —it is carbanilidoamidoazotoluene. On reduction with stannous chloride and hydrochloric acid a white body, probably amidotolylphenyl urea—

melting at  $195^\circ C.$ , is obtained.

**Benzene-azo- $\beta$ -naphthylamine** is acted upon by phenyleyanate at  $125^\circ C.$ , and an orange substance  $C_{20}H_{18}N_4O$ , melting at  $205^\circ C.$ , is formed. By reduction a white body melting at  $290^\circ C.$  Amidonaphthylphenyl urea—

$C_{10}H_6(NH_2)NH.CO.NH.C_6H_5$ <sup>a</sup> is obtained.

To prove whether *o*-amido-azo-compounds are genuine azo-bodies or quinone derivatives benzene-azo- $\beta$ -naphthylamine was treated with 2 mols. of phenyleyanate at  $150^\circ C.$  A dark liquid and a light yellow crystalline mass were the result of this reaction. From the latter three different substances were isolated:—(1.) A compound crystallising in yellow needles melting at  $252^\circ C.$  (2.) Diphenyl urea. (3.) Monocarbanilido-benzene-azo- $\beta$ -naphthylamine. No. 1 product is, according to the author's view, either—

and proves the ortho-amido-azo-compounds to be quinone derivatives.

**Ortho-amido-azo-toluene** is therefore to be considered as—

**Action of Benzaldehyde on Ortho-amido-azo-toluene.**—On dissolving ortho-amido-azo-toluene in an excess of benzaldehyde, crystals are formed after a short time, and when recrystallised from alcohol form colourless needles melting at  $220^\circ C.$ , and having the formula  $C_{21}H_{19}N_2$ . The corresponding benzene compound is orange-yellow.

**Benzene-azo- $\beta$ -naphthylamine** is acted upon by benzaldehyde only after heating a mixture of equal molecules for some time at  $140^\circ C.$  As the result a white substance is obtained in microscopic crystals, melting at  $193^\circ C.$ , and having the formula  $C_{20}H_{17}N_2$ . Boiling this body with hydrochloric acid caused decomposition, and heating it under pressure only formed the hydrochloride. Ordinary benzylidene compounds have no basic character, and are decomposed by boiling with hydrochloric acid into benzaldehyde and the original base. The constitution of this body is either—

**On 2, 7.—Dihydroxy-naphthalene.** A. Clausius. Ber. **23**, 517—529.

This compound crystallises from hot water in long needles melting at  $190^\circ C.$  Its acetyl compound forms white leaves, melting at  $136^\circ C.$ , whilst its benzoyl compound crystallises from alcohol in colourless leaves, melting at  $139^\circ C.$

**1, 2, 7.—Hydroxy-naphthoquinone oxime—**

is obtained by the action of nitrous acid on the dihydroxy compound. It forms brownish-yellow needles melting at about  $235^\circ C.$  No acetyl compound could be prepared from it. The author did not succeed in introducing a second nitroso group.

**1, 2, 7.—Dihydroxyamidonaphthalene—**

The free base is very unstable; the hydrochloride is more stable and can be easily prepared by reducing the nitroso compound with stannous chloride.

**7, 1, 2.—Hydroxy-naphthoquinone—**

is an isomeric of Juglone and the ordinary hydroxy-naphthoquinone. It is obtained from the above described amido compound by oxidation with ferric chloride as a reddish-brown amorphous precipitate which did not admit of crystallisation. It is soluble in sulphites, but cannot be reprecipitated by acids. Chlorine in presence of acetic acid acts on the hydroxyquinone, but no pure products could be separated from the resinous mass.

**1, 2, 7.—Benzene-azo-dihydroxy-naphthalene—**

obtained by combining diazobenzene chloride with an alkaline solution of the dihydroxy-naphthalene. Recrystallised from alcohol it forms bluish-green needles, melting at  $220^\circ C.$ , soluble in alkalis. Its acetyl compounds form white needles, melting at  $195^\circ C.$

1, 3, 6, 8, 2, 7.—*Tetra-chlorodihydroxynaphthalene* was obtained by reducing the deachlorodiketone with stannous chloride. Long fine needles, melting at 176° C., soluble in alcohol and hot glacial acetic acid. Its acetyl compound crystallises in needles, melting at 196° C.

*Decachloro-2, 7.—Diketohydronaphthalene—*

is the final product obtained by the action of chlorine on the dihydroxy compound in a solution of acetic acid. Colourless crystals, melting and decomposing at 200° C., with difficulty soluble in alcohol, glacial acetic acid, and benzene.

2, 7.—*Dianilidonaphthalene—*  
(2, 7.—*Phenylamidonaphthalene*)—

is formed by heating the dihydroxy compound with aniline and calcium chloride for 18 hours at 240°—290° C. By treating the brownish mass with alkali the mono- and dihydroxy-compounds are removed. Bright colourless plates, melting at 168° C. The diaetyl compound melts at 197.5° C. Its benzene-azo-compound, obtained by the action of the diazobenzene chloride on the dianilido-compound, forms brownish needles when recrystallised from alcohol.

2, 7.—*Hydroxynilidonaphthalene—*

forms small needles, melting at 163° C., easily soluble in glacial acetic acid, alcohol, and benzene.—A. L.

*On Combinations of Benzyltrichloride with Phenols.*  
O. Döbner. Ann. 257, 56—60.

BENZYLTRICHLORIDE acts only on such phenols as hold the para-position free with regard to the hydroxy-groups.

*Benzyltrichloride and α-Naphthol.*—On heating 1 mol. of benzyltrichloride with 2 mols. of α-naphthol on the water-bath, hydrochloric acid is evolved and a dark green melt formed. After the evolution of hydrochloric acid is at an end the melt is boiled with dilute caustic soda, from which after filtration the α-Naphthol-benzoin is precipitated by hydrochloric acid. For further purification it is dissolved in absolute alcohol and reprecipitated by concentrated hydrochloric acid. It could not be obtained in crystals, but forms a reddish-brown powder, insoluble in water, soluble in alcohol, ether, benzene, and glacial acetic acid, with a yellowish-red colour. It combines with alkalis and acids, if its alcoholic solution is treated either with one or the other. A benzoyl- or acetyl-compound could not be prepared. On fusion with caustic potash, benzoic acid and α-naphthol were obtained. By the action of zinc and glacial acetic acid it is converted into an amorphous colourless powder, which seems to be, according to analysis, dihydroxydinaphthylphenylmethane,  $C_{26}H_{20}O_2$ :  $(C_{10}H_6.OH)_2$ . The constitution of the α-Naphthol-benzoin is not yet finally decided; it is either—

or

One mol. of benzyltrichloride and 2 mols. of β-naphthol react, forming a body melting above 350° C., insoluble in alkalis and acids, crystallising from nitrobenzene in small white needles, insoluble in water, alcohol, ether, and benzene. It is isomeric with the α-compound, and in accordance with its properties, is *o*-benzoyl-β-naphthylether—

—A. L.

*On Pyrogallol-Benzoin.* O. Döbner and A. Förster.  
Ann. 257, 60—68.

THE blue colouring matter obtained by the action of pyrogallol on benzyltrichloride is prepared in the following way:—One mol. of the benzyltrichloride is gradually added to 2 mols. of the phenol and the mixture heated to 160° C., until evolution of hydrochloric acid ceases. The melt is boiled with water to remove the excess of pyrogallol and to convert the chloride first formed into the carbinol. The colouring matter is purified by crystallisation from glacial acetic acid and forms small dark green crystals. Yield from 100 grms. of pyrogallol = 60 grms. of pure colouring matter. The pyrogallol-benzoin is nearly insoluble in water, petroleum spirit, benzene, or carbon bisulphide, more easily soluble in alcohol, ether, hot chloroform, alkalis, alkaline carbonates, and a hot solution of sodium acetate. Its formula is  $C_{23}H_{15}O_{11}$ . From the neutral solutions of the ammonium salt of pyrogallol-benzoin most metallic salts precipitate blue-violet amorphous lakes. It is, however, of little value as a colouring matter. It dyes unmordanted cotton or cotton mordanted with tartar-emetic and tannin only very faintly. Better results are obtained with aluminium, iron, and other similar mordants; the colours are, however, not fast towards acetic acid.

*Tetra-acetyl Pyrogallol-benzoin*,  $C_{38}H_{20}O_{11}(C_2H_3O)_4$ , forms light red crystals, melting at 208° C., with difficulty soluble in alcohol and ether, insoluble in water.

*Tetra-valeryl Pyrogallol-benzoin*,  $C_{38}H_{20}O_{11}(C_4H_7O)_4$ , red prisms from hot alcohol or acetone, melting at 251° C.

*Tetra-valerylhydro Pyrogallol-benzoin*,—

red needles soluble in alcohol or acetone, melting at 227° C., different from the above-described compounds, having lost one molecule of water.

*Hydropyrogallol-benzoin*,  $C_{19}H_{11}O_5 + 3 H_2O$ , was obtained by reduction of the colouring matter with glacial acetic acid and zinc dust. Either reddish crystalline powder or long silky needles of the constitution—

Concentrated sulphuric acid forms a sulphonic acid with pyrogallol-benzoin. The constitution of the pyrogallol-benzoin is expressed by the formula—

—A. L.

On *Ortho-cresol-benzoin*. G. Schröter. Ann. **257**, 68—75.

Forty-six grms. of benzyltrichloride are gradually added to 50 grms. of ortho-cresol and the mixture is heated on the water-bath until the evolution of hydrochloric acid ceases. The excess of ortho-cresol is removed by distillation with steam. The colouring matter is dissolved in dilute caustic soda, filtered, and precipitated by hydrochloric acid. On heating with sodium bisulphite it is dissolved, and after filtration reprecipitated. It melts at  $220^{\circ}$ — $225^{\circ}$  C., and its formula is  $C_{21}H_{20}O_3$ . An acetyl compound could not be prepared. Its constitution is—

on reduction of this compound with sulphurous acid,

*Dihydroxydimethyl-triphenylmethane*—

melting at  $170^{\circ}$ — $171^{\circ}$  C., is formed, easily soluble in the usual solvents, water excepted. With acetic anhydride a diacetyl-compound,  $C_{21}H_{18}O_5(C_2H_3O)_2$ , is produced; light yellow needles, melting at  $91^{\circ}$  C. Its benzoyl-compound,  $C_{21}H_{18}O_5(C_7H_5O)_2$ , crystallises in white leaves, melting at  $91.5^{\circ}$  C. By the action of bromine a dibromide,  $C_{21}H_{18}O_5Br_2$ , is obtained; yellowish-red needles, melting at  $130^{\circ}$  C., insoluble in water, soluble in alcohol, benzene, and glacial acetic acid. With nitric acid a dinitro-compound,  $C_{21}H_{18}O_5(NO_2)_2$ , is formed, soluble in benzene, alcohol, and glacial acetic acid, and melting at  $127^{\circ}$  C.

On fusing ortho-cresol-benzoin with caustic potash dimethyl-dihydroxybenzophenone is obtained, colourless needles, easily soluble in alcohol, ether, and glacial acetic acid, with difficulty in benzene, and melting at  $138^{\circ}$  C.

—A. L.

#### PATENTS.

*Improvements in Producing Yellow Colouring Matter suitable for Dyeing and Printing.* J. Erskine, Glasgow. From "The Farbenfabriken vormals Friedrich Bayer and Co.," Elberfeld, Germany. Eng. Pat. 9162, June 19, 1884. Amended March 5, 1890. 4d.

Is the original specification the patentee claimed the production of a yellow colouring matter by diazotising benzidine and combining the tetrazodiphenyl thus formed with *salicylic acid*, *phenol*, or *cresol* (this Journal, 1885, 400). The claim is now restricted to the use of *salicylic acid* alone for the combination with the tetrazo compound.

There are one or two minor emendations in the text, which do not affect the claim.—O. H.

*Improvements in the Manufacture of Colouring Matters.* J. E. Bedford, Leeds. Eng. Pat. 6777, April 23, 1889. 6d.

THE subject-matter of this patent has been incorporated in No. 6778 of 1889 (see this Journal, 1890, 385).—T. A. L.

*The Production of New Bluish-black Colouring Matters.* S. Pitt, Sutton. From L. Casella and Co., Frankfurt-on-the-Maine, Germany. Eng. Pat. 7977, May 13, 1889. 6d.

This is an extension of Eng. Pat. 9214 of 1885 (this Journal, 1886, 427), and provides for the combination of the diazo-azo compounds there described with substituted *m*-diamines and *m*-amido-phenols, producing black colouring matters, fast to milling, and some of them having an affinity for cotton. The two following examples illustrate the method. (1.) 34.7 kilos. of sodium  $\alpha$ -naphthylamine disulphonate are diazotised, combined with 18 kilos. of  $\alpha$ -naphthylamine hydrochloride, and this compound re-diazotised by the addition of 7 kilos. of sodium nitrite. It is then combined with an alcoholic solution of 16 kilos. of tetramethyltolylenediamine and an equivalent quantity of sodium acetate. The colouring matter remains almost entirely in solution, and crystallises out on distilling off the alcohol. It dyes wool a bluish-black from a neutral bath containing salt. (2.) The diazo-azo compound prepared as above is combined with an alkaline solution of 18 kilos. of

*m*-hydroxydiphenylamine (phenyl-*m*-amido-phenol), and the dyestuff which forms immediately is precipitated by the usual means. It dyes wool in a neutral or acid bath a black of a reddish shade, and can also be used as a cotton dye. In place of  $\alpha$ -naphthylaminedisulphonic acid, the sulphonic acids of aniline, toluidine, xylylene, benzidine, its homologues and amidostilbene may be employed. With respect to Eng. Pat. 4825 of 1889 (this Journal, 1890, 172) no claim is made in this patent to the invention described therein.

—T. A. L.

*Improvements in the Production of Blue-Black Colouring Matters.* H. H. Lake, London. From A. Leonhardt and Co., Muhlheim-on-the-Maine, Germany. Eng. Pat. 8264, May 17, 1889. 4d.

THE nitroso derivatives of tertiary aromatic amines, when heated with *m*-hydroxydiphenylamine in the proportions of three molecules of the former to one of the latter, yield blue-black colouring matters. 16.8 kilos. of nitrosodimethylaniline hydrochloride are heated with 5.6 kilos. of *m*-hydroxydiphenylamine and 16 litres of spirit until all the nitrosodimethylaniline has disappeared. The spirit is then distilled off, the residue dissolved in hot water, slightly acidulated with hydrochloric acid, filtered, and the colouring matter precipitated with salt.—T. A. L.

*Improvements in Preparing Colouring Matters of the Oxyketone Group, suitable for Dyeing and Printing with the Aid of Morchants.* J. Y. Johnson, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 8373, May 20, 1889. 6d.

New colouring matters which dye yellow on an alumina mordant are obtained by condensing (1) pyrogallol with certain carboxyl derivatives of the aromatic and fatty series, viz., benzoic acid, *p*-chlorobenzoic acid, salicylic acid, *m*-hydroxybenzoic acid, *p*-hydroxybenzoic acid, *m*-cresotic acid,  $\beta$ -resorcylic acid, propionic acid, *n*-butyric acid, valeric acid; (2), gallic acid with certain phenolic bodies, viz., resorcinol and pyrogallol. The condensation is performed in presence of sulphuric acid, chloride of zinc, or tetrachloride of tin. Trihydroxybenzophenone, which dyes cotton mordanted with alumina a golden-yellow colour, is obtained by heating 1 kilo. of pyrogallol and 1 kilo. of benzoic acid with 3 kilos. of zinc chloride to  $140^{\circ}$  C. The reaction is complete in about three hours, when a sample of the melt dissolved in water should deposit no laminae of benzoic acid on cooling, but light yellow needles of the new compound. The whole melt is then dissolved in water, boiled with animal charcoal, filtered and allowed to crystallise. The trihydroxybenzophenone thus obtained is very slightly soluble in cold water, readily soluble in alcohol, ether, acetone and glacial acetic acid. It dissolves in concentrated sulphuric acid and in alkalis with an intense yellow colour. The alkaline solutions in presence of an excess of caustic potash or soda rapidly absorb oxygen and form a green product. All these compounds contain hydroxyl groups in the ortho-position, and the colours obtained from them are said to be as fast as alizarine dyes. The melting points and properties of several of these new oxyketones are given in the patent.

—T. A. L.

*Improvements in Preparing Colouring Matters of the Oxyketone Group suitable for Dyeing and Printing with the Aid of Morchants.* J. Y. Johnson, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 9428, June 6, 1889. 4d.

AN extension of Eng. Pat. 8373 of 1889 (see preceding abstract), describing the preparation of the same compounds by substituting for the carboxyl derivatives the acid chlorides or anhydrides of the acids so far as known. For example, in place of heating pyrogallol with benzoic acid, the latter may be replaced by benzoyl chloride or benzoic anhydride.

—T. A. L.

*Process for the Manufacture of Yellow to Orange Colouring Matters.* T. R. Shillito, London. From A. Feer, Brombach, Germany. Eng. Pat. 12,549, August 8, 1889. *Ad.*

TETRAMETHYLDIAMIDO-DIPHENYLMETHANE, when heated with sulphur in presence of ammonia or a primary aromatic amine, forms yellow and orange dyestuffs. 12.7 kilos. of tetramethyldiamido-diphenylmethane, and 3.2 kilos. of sulphur are heated to 140° C. in an autoclave provided with an inlet and outlet pipe; 120 kilos. of salt and 7 kilos. of ammonium chloride are then added, the temperature raised to 175°, and a slow current of ammonia passed through the melt for 7–8 hours. When cold it is treated with cold water to remove the salt, dissolved in hot water and reprecipitated with salt. The colouring matter dyes cotton mordanted with tannin a pure yellow shade. An orange-red dyestuff is obtained by heating 25 kilos. of tetramethyldiamido-diphenylmethane, 20 kilos. of aniline, and 9.5 kilos. of sulphur to 200° C. When no more gas is evolved the melt is dissolved in 300 kilos. of 40 per cent. acetic acid, diluted with water, filtered, and the colouring matter precipitated with zinc chloride and salt. It forms a bright red powder and dyes mordanted cotton orange-red.—T. A. L.

*Production of New Red Colouring Matters.* S. Pitt, Sutton. From L. Casella and Co., Frankfort-on-the-Maine, Germany. Eng. Pat. 12,560, August 8, 1889. *Ad.*

HITHERTO in the benzidine series red colouring matters have only been obtained by combining benzidine and other para-diamines with naphthylamine sulphonic acids. The naphthols and their sulphonic acids only yield blue to violet colours. It has, however, been found that by alkylating or benzylating certain of the dyestuffs obtained from naphthol sulphonic acids and tetrazo-diphenyl, red colouring matters are formed. The process is worked as follows:—18.4 kilos. of benzidine are diazotised and added to a cooled solution of 40 kilos. of sodium  $\beta$ -naphthol- $\gamma$ -disulphonate. After a short time 10 kilos. of phenol are added, the whole heated to boiling, and the colouring matter precipitated by salt and filtered off. This is then dissolved in 200 litres of water, 200 kilos. of alcohol and 4.5 kilos. of caustic soda, and heated with 12 kilos. of ethyl bromide for 24 hours under pressure at 60° C. On cooling, the new colouring matter separates in shining crystals. It dyes unmordanted animal or vegetable fibres scarlet from an acid, neutral or alkaline bath.—T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

### PATENT.

*Process for Separating the Wool from Pieces of Rabbit Skins and other Skins of a similar Kind.* C. Puech, Paris, France. Eng. Pat. 10,010, June 18, 1889. *Ad.*

THE pieces with the fur on are "effectually" boiled in water, washed, and afterwards dried at 70° to 85° C. The albuminous and gelatinous constituents are hereby entirely removed from the leather, which loses its cohesive strength. The dried leather having thus become brittle, a simple crushing operation by means of stamps, crushing cylinders, &c., reduces it to powder, liberating the whole of the wool. The crushing is best carried out as soon as the material issues from the drying apparatus, and while still very hot. The material is then sifted or bolted, to separate the dust from the wool.—H. S.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*On Turkey-Red Oil.* P. Lochtin. Dingl. Polyt. J. 275, 594–603.

THIS article treats of the conditions necessary for successful application of the "Sulphated Oil Process" in dyeing cotton with Alizarine red. All recipes for preparing the oil agree in requiring the sulphuric acid to be added very slowly to the oil and with constant stirring, in order to avoid heating during the mixing and the evolution of sulphurous acid in any large quantity. The author describes experiments which demonstrate that the risk of spoiling the product is much less than is commonly supposed. He shows that at temperatures below 70° any evolution of sulphurous acid must be due to albuminoid substances present as impurities in the oil, the oil itself not giving rise to sulphurous acid below that temperature. (The paper is practically confined to the treatment of castor oil, as that is the only one in common use in Russia for Turkey-red dyeing.) The endeavour to avoid any evolution of sulphurous acid may even lead to very imperfect results being obtained, for a low temperature of reaction will leave much of the oil undecomposed—the author's view being that only the free fatty acid is of use in the dyeing process. In working on the large scale with 1,000 kilos. of castor oil the author adopts the following procedure. In winter 20 to 30 per cent., and in summer 15 to 20 per cent. of concentrated sulphuric acid are used. About one half of the acid is stirred into the oil during 9 hours of the working day and the mixture is allowed to stand overnight. On the next day the second half of the acid is stirred in and the mixture left to stand until a sample gives a clear solution when diluted with water, 5 to 10 drops being shaken with distilled water in a test-tube. The bulk is then mixed with an equal weight of water. It is necessary to test a sample frequently, as the mixture will give a cloudy solution in water if either too short or too long a time be given for the reaction. The proportion of free fatty acid may be increased if desired by using hot water for dilution. On allowing the mixture to stand, the oily part separates and floats on the aqueous acid layer, and it is drawn off to be treated with alkali. As some of the best preparations contain only 2 to 5 parts of  $\text{SO}_3$  to 100 parts of fatty acids, whereas the sulphonated fatty acid should contain 6 to 15 times more  $\text{SO}_3$ , it is evident that the sulphonated fatty acid is not of essential importance, and this conclusion is corroborated by an experiment on the large scale in dyeing with fatty acid prepared by saponification with alkali in which, of course, no sulphonated compound was present; but although the shade produced was very fine, the oil-bath showed a tendency to frothing, which caused the dyeing to be somewhat uneven. In order to fit the sulphated castor oil for use as a mordant, it has to be partially neutralised by an alkali, and the author finds that sufficient alkali has been added when it amounts to more than a quarter and less than half that required for theoretical neutralisation. In practice the alkali, either caustic soda or ammonia, or both, is added to the emulsified fatty acid until the mixture becomes suddenly clear, when the right degree of neutralisation has been attained. The use of ammonia for neutralisation has certain advantages, especially in the finishing and printing of steam colours, because the alkali volatilises and leaves only the free fatty acid on the cloth. The reason why castor oil has come to be selected as the most suitable for Turkey-red dyeing is its property of forming a soluble soap with a minimum proportion of alkali. Solutions of other fatty acids give emulsions rather than clear solutions when the proportion of alkali falls much below that required for complete neutralisation. Again, the decomposition of the oil by the action of sulphuric acid is more complete with castor oil than with any other oil which can be used, and maximum decomposition is essential to the achievement of the best results. A certain proportion of undecomposed oil has, however, the advantage that it lessens the tendency to frothing, and the decomposition by means of sulphuric acid in the case of castor oil provides for the ready attainment of this condition.—G. H. B.

*Thioflavine.* A. Scheurer. Bull. Ind. Soc. Mulhouse, 1889, 563.

Nothing further than what has already appeared (this Journal, 1889, 608).—E. B.

*Heilmann's Steaming Machine for Worsted Yarn.*

P. Heilmann. Bull. Ind. Soc. Mulhouse, 1889, 564—567.

In the usual process of steaming woollen yarns as effected by placing the cops, canettes, &c. in baskets inside closed steaming vessels, and there submitting them to the action of steam for some three-quarters of an hour, the results obtained are unsatisfactory. The cops at the top of the baskets are excessively steamed, becoming elongated and twisted at the ends, rendering difficult the winding off of the yarn, whilst the cops at the bottom are insufficiently steamed. These defects are overcome in the machine here described by creating a vacuum in the chamber in which the yarn is placed before admitting the steam, and the steaming is done in a minute or a minute and a half.

The steaming-vessel A (Figs. 1, 2, and 3) is provided with a false roof of sheet copper, which serves to protect the wool from being iron-stained by drops of condensed

Fig. 1.

Fig. 2.

Fig. 3.

moisture, and is capable of holding two baskets containing each 20 to 25 kilos. of wool. The vacuum is produced by

the steam-injector C, the steam blowing away through C'' and aspirating the air through C'''. B is a second chamber into which the steam enters through a layer of boiling water at the bottom; b' (Fig. 1) is an over-flow pipe. There are also arrangements for the supply of water and regulation of the steam supply. c (Fig. 2) is the tap which places the two chambers in communication.—E. B.

*Chromium Oxides and Salts.* Prud'homme. Bull. Soc. Ind. Mulhouse, 1889, 599—609.

*Chromic Hydrate*, as precipitated in the cold from either a green or violet chromic salt, is soluble in sodium hydrate, the solution on standing depositing chromic hydrate in a gelatinous condition. According to Fieuny, when the alkaline solution is boiled, a precipitate of anhydrous chromic oxide is formed. The author finds both precipitates, namely, that obtained in the cold and that obtained on boiling, to be identical, having each, when dried at 100°, the composition  $\text{Cr}_2\text{O}_3 \cdot 5 \text{H}_2\text{O}$ .

On mixing boiling solutions of chromic alum and sodium hydrate in excess, a pale-green, powdery precipitate is produced, which settles rapidly, differing in this respect from the dark-green, gelatinous precipitate produced at a lower temperature. The attempt was made to fix this powdery precipitate on cotton tissues by preparing in a chromium salt, drying and fixing in a boiling solution of caustic soda containing 50 grms. of caustic soda of 36° B. per litre, better results being so obtained than with carbonate of soda, even at the rate of 200 grms. of the latter per litre. This powdery precipitate also contains five molecules of water when dried at 100°.

As regards the colour of the precipitate, it is found that the normal green colour always characterises the precipitates obtained by the addition to a violet chromic salt of an amount of alkali insufficient to completely precipitate it. Ammonium hydrate for instance, under this condition, yields a yellow-green precipitate, whereas when added in excess it produces a violet-blue precipitate. Sodium hydrate, again, when not added in excess to a solution of violet salt, yields a green precipitate dissolving in acids with a violet colour, but when even a slight excess of soda is used the precipitate dissolves in acids with a green colour. A green chromic salt, precipitated at the boil with ammonium hydrate not in excess, yields a green hydrate forming green salts; with excess of the reagent a pearl-grey precipitate is produced, which dissolves in cold acids with a violet colour. The uncrystallisable green salts in time become violet and crystallisable. Etard states that traces of potassium nitrite or thiocyanate rapidly induce this change. On the other hand, the author finds that the addition to a violet salt of small quantities of sodium bisulphite or borax changes its colour into green, and Etard has remarked a similar change under the influence of arsenic acid and arseniates. From these considerations it is inferred that the difference in colour is purely physical and of only momentary value, as the green salts at ordinary temperatures are slowly tending towards the stable violet state. Chemically, a green salt may be defined by the minimum temperature required for the transformation of a violet salt, namely, 65°, or still better, 100°, special reactions of the chromic salts taking place only at this latter temperature.

*Chromous Chloride* exists in two modifications, coloured respectively blue and green, a fact which seems to have escaped the notice of chemists. The blue salt is obtained by reducing a chromic salt with zinc and a little hydrochloric acid; it reduces stannous chloride and colouring matters. Heated in absence of air it becomes green, its blue colour returning on cooling. When a green chromic salt is reduced at 100° with zinc dust, green chromous chloride is obtained which only gradually passes into the blue form; the former modification will not reduce stannous chloride at the boil, but does so at lower temperatures. The existence of two modifications of chromous chloride explains the reason of the solubility of anhydrous chromic chloride in a 1 per cent. solution of chromous chloride.

*Chromic Chlorate* possesses either a green or violet colour according as it is prepared at or below 65°. As

prepared by double decomposition between chrome alum and barium chlorate it holds in solution barium sulphate, which may be precipitated by boiling or addition of hydrochloric acid. On heating a solution of chromium chlorate to 100°, chlorine is evolved and the liquid becomes reddish-yellow in colour, and then contains chromic acid and oxides of chlorine; this liquid constitutes a powerful oxidising mixture, and at one time was employed by the author for the purpose of rendering aniline blacks ungreenable.

The chromium salts have the singular property of carrying with them into alkaline solution the oxides of certain metals; ferric oxide thus dissolves very well, forming a clear brown solution which keeps for weeks without depositing either ferric or chromic oxide; cupric oxide forms a double salt of a fine blue colour, depositing cuprous oxide on boiling, and leaving sodium chromate in solution. When the copper salt is in excess, the liquid, after boiling, is of a greenish-yellow colour, and contains copper chromate along with sodium chromate, and this liquid, after some months' standing, deposits chromic oxide and insoluble copper chromate, becoming itself blue, and then containing no chromium salts. The blue liquid on boiling deposits a mixture of cuprous and cupric oxides; if kept in the cold the blue colour again becomes green, depositing cupric oxide and eventually containing nothing but cuprous oxide.

Berzelius has stated that chromic hydrate dissolves easily in sulphurous acid in the cold, and on boiling a green powdery precipitate of *chromic sulphite* is produced. The author finds that the solvent action of sulphurous acid and also that of alkaline bisulphites is limited to the chromic hydrate precipitated in the cold by ammonia or sodium hydrate not in excess. The yellow-green solution of chromic hydrate in sodium bisulphite after the lapse of some time deposits chromic sulphite, the solution remaining green. Addition of a large excess of ammonia to the freshly-prepared green solution transforms it into a magnificent red liquid, which probably contains a chromamine of the class discovered by Frémy. Such a solution can be used for mordanting cotton with chrome, but better results are obtained with the following mixture:—45 parts of potassium bichromate, 20 of sodium carbonate, 100 of ammonium bisulphite of 36° B., 100 of ammonia, and 1,000 of water, the pieces being prepared in this solution, dried, and aged or steamed.

The oxide of chromium obtained by strongly heating the dried hydrate is of a grey-black colour. Crystallised chromic oxide may be prepared by fusing a mixture of potassium bichromate and metallic tin, being thus obtained in small shining leaflets of a pale green colour, which are not attacked by the strongest acids.—E. B.

#### *Notes on the Dyeing of Aniline Black.* J. Persoz. Bull. Soc. Ind. Mulhouse, 1889, 609—615.

This is a sealed note deposited with the Industrial Society of Mulhouse in 1875, and opened November 1889, for the purpose, as the author states in a preface to the note, of showing the state of advancement of aniline-black dyeing in 1875. At this period several manufacturers at Rouen, notably Daniel Fauquet, were dyeing by a single bath process, which had previously been practised by Bretonnière of Laval, and others.

In a previous sealed note opened towards the end of 1871 the author described a mode of dyeing aniline-black, based on the method suggested by Paraf-Javal, in which potassium bichromate and aniline salts were employed. The modification proposed consisted in applying the two compounds separately, padding the cloth or saturating the yarn with the solution of one of them, and then spraying the solution of the other over the surface. Excellent results were obtained, but the process was not a commercial success, owing to the want of a suitable spraying machine.

In the present note two methods for dyeing aniline-black are described. In the first of these, several baths are used, the cloth passing successively through the various baths of one range and then similarly through two or more such ranges, being well squeezed on emerging from each bath. The range of baths employed is as follows:—

First bath: neutral solution of ferric nitro-sulphate at 20° B.

Second bath: 100 parts of water, 10 of potassium bichromate, 1 of ammonium chloride.

Third bath: 100 parts of water, 10 of nitric acid, 7·5 of aniline.

Fourth bath: water.

In the second method the dyeing is effected in a single bath. The bath is composed of a mixture of three solutions separately prepared, consisting of (1) ammonium chloride, manganese chloride, copper sulphate, common salt, and ferric nitro-sulphate; (2) potassium bichromate and sulphuric acid; and (3) aniline salts and chloride of potash. After dyeing, the cotton is worked at 50° in a fixing-bath of potassium bichromate and other oxidising salts, then boiled in a 1 per cent. solution of acetic acid, and finally soaped for an hour at the boil with a 0·2 per cent. solution of soap.

—E. B.

#### PATENTS.

*Improvements in the Process and Means for Dyeing Hides.* J. Kristen, Brünn, Austria. Eng. Pat. 8191, May 16, 1889. 8d.

The dressed hide which is to be dyed is stretched over a table supported on a vertical shaft and capable of being rapidly rotated. A sufficient quantity of dye-liquor is run from a projecting swivel pipe on to the middle of the table, which is then set in motion, the centrifugal action produced causing the liquor to saturate every portion of the hide. The table is provided with a rimmed edge to prevent the dye-liquor being "thrown off horizontally," and is enclosed in a tank, arrangements being made for returning to the table the liquor which collects in the tank. In cases where it is desirable to subsequently sadden the dyed colours with iron or copper sulphate, it is recommended, for facility of removal of the hide to a separate table, that the hide be attached to a copper plate.—E. B.

*Improvements in the Production of Coloured Compounds of Gallacetophenone within or upon Animal and Vegetable Fibres.* J. Y. Johnson, London. From "The Badische Aniline und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 9429, June 6, 1889. 6d.

GALLACETOPHENONE (J. Prakt. Chem. 23, 147—538), when combined with mordants, is capable of dyeing animal or vegetable fibres. It is employed preferably as a paste containing 10 per cent. of the dry substance, and with various mordants will give the following colours:—

*Yellow.*—37½ lb. of gallacetophenone paste, 15 lb. of aluminium thiocyanate of 1·15 sp. gr., 7½ lb. of calcium acetate solution of 1·075 sp. gr., 7½ lb. of acetic acid of 1·045 sp. gr., and 32½ lb. of thickening.

*Yellowish-Brown.*—37½ lb. of gallacetophenone paste, 15 lb. of chromium thiocyanate liquor of 1·2 sp. gr., 7½ lb. of acetic acid of 1·045 sp. gr., and 40 lb. of thickening.

*Black.*—37½ lb. of gallacetophenone paste, 15 lb. of acetate of iron liquor of 1·116 sp. gr., 7½ lb. of acetic acid of 1·045 sp. gr., and 40 lb. of thickening.

The goods after printing are subsequently steamed, and finally soaped, washed, and dried.—T. A. L.

*Improvements in Doctors Employed in the Printing of Textile Fabrics.* J. Archer, Radcliffe. Eng. Pat. 18,145, November 13, 1889. 6d.

THE front edge of the improved doctor-blade is constructed of two or three layers of steel, brass, or other suitable material, soft-soldered or brazed together, by which means increased strength and durability are secured, whilst the necessary suppleness and elasticity are retained by the thin back portion of the blade. The same end may be gained by constructing the blade out of a single solid sheet of metal of the thickness required for the front edge, the back part being cut or ground down.—E. B.

## VII.—ACIDS, ALKALIS, AND SALTS.

*Recent Determinations of the Specific Gravities of Sulphuric Acids of different Strengths.* G. Lange and M. Isler. *Zeits. f. angew. Chem.* 1890, 129—136.

For a number of years the table of specific gravities given by Kolb has been the one used, as it agrees very well with that of Bincau, previously in general use. Bincau made no determinations over 98.5 per cent. of  $\text{H}_2\text{SO}_4$ , but Kolb gave a result for the pure hydrate,  $\text{H}_2\text{SO}_4$ . By a series of distillations he obtained an acid which he stated contained 99.72 per cent. of the hydrate. This seems to be an error, as other observers have not been able by these means to obtain an acid containing more than 98.5 per cent. However, to this acid Kolb added sulphur trioxide, and heated the mixture to  $200^\circ$  in a sulphuric acid bath to drive off the excess of trioxide; the product so obtained he considered

to be the pure hydrate  $\text{H}_2\text{SO}_4$ , since his analysis of it showed 99.95 per cent. The analysis was gravimetrically performed with barium chloride. Fresenius has shown that in this method of analysis several grave sources of error exist, for in strongly acid solutions the results are apt to be too low, whilst excess of barium chloride has a great tendency to bring out results which are too high. Kolb gives no account of any precautions used. Furthermore, the pure hydrate,  $\text{H}_2\text{SO}_4$ , gives off anhydride at a temperature of  $30-40^\circ$ , and consequently at  $200^\circ$ , the temperature at which the acid was said to have been obtained, such a product is impossible.

It has since been repeatedly shown that the greatest concentration obtainable by heating is about 98.5 per cent., and furthermore that the maximum density is attained with a percentage of 97.5—97.7, from which point up to 100 per cent. the density decreases. On such grounds as these, redetermination of the specific gravity of acids varying in concentration from 90—100 per cent. has been made (Lange

SPECIFIC GRAVITY OF SULPHURIC ACID.

The specific gravities on the left-hand side refer to the lower curve; those on the right-hand side to the upper curve.

— Lange and Isler, at  $15^\circ\text{C}$ . (in vacuo).

- - - Kolb, at  $15^\circ\text{C}$ . (corr.).

and Naef, Chem. Ind. 1883, 37; this Journal, 1883, 279). Nevertheless, the old erroneous table of Kolb for these higher concentrations has been retained without remark by Bolley and Stahlschmidt ("Chemisch-technische Untersuchungen," 1889 edition). Work has also been published on this point in recent years by Kohlrausch, Schertel, Winkler, and Mendeleff. The present publication of the authors deals not only with the acid from 90—100 per cent., but also with acid varying in concentration the whole way below this. The result, as seen from the accompanying curve, is that more carefully conducted experiments have removed the deviations found by Kolb, and have ascertained the densities of acid below 3 per cent. to be decidedly in error. The percentages are given as abscissæ, the specific gravities as ordinates.

For the purpose of the tables given the curve was made on a large scale so that accurate readings were obtained by interpolation. The results are given for intervals of 1 Tw. (intervals in specific gravity of .005) since the Baumé scale and the "rational" Baumé scale in use are so conventional as to be to a certain extent misleading, for the "rational" scale is based on the false assumption that the pure hydrate,  $H_2SO_4$ , has the sp. gr. 1.842 at 15° C.

On the other hand the reading 66 with the sp. gr. 1.842 is by some taken for fuming sulphuric acid. The concentration of this acid, however, varies from 92 to 96 per cent. and its true specific gravity at 15° is 1.830—1.8405, though the commercial product possesses a specific gravity varying with the amount of impurities. Again, if it be assumed that 66° on the "rational" Baumé be equivalent to a specific gravity of 1.842, then 93 per cent. acid is only 65½, and 96 per cent. acid only 65½ B.

In the tables the percentages are given to hundredths, only, however, to enable more accurate determination to the first decimal place.

The values given are for the chemically pure substance. In practice, however, the deviations up to about 1.75 may be neglected; in the case of stronger acids the impurities present are so considerable that the specific gravities are very appreciably higher than the values given, so that the buyer cannot expect an acid of sp. gr. 1.840 to contain 95.6 per cent.

Observations should be made as near 15° C. as possible, or corrected by known means. In the preparation of the tables given, the experiments were made at 15° C. and the results reduced by calculation, to water at 4° C. and vacuum.

*On the Production of Sulphuretted Hydrogen from Solutions of Calcium Sulph-hydrate by means of Steam.*  
B. Deutecom and F. Roth. Chem. Ind. **13**, 25—28.

A DETAILED account of experiments on a semi-industrial scale illustrated with tables showing the course of the reactions and the quantitative results obtained. On heating a solution of calcium sulph-hydrate to boiling, sulphuretted hydrogen is evolved and crystalline calcium hydrate deposited. When the solution has a density above 20° B. scarcely any steam is evolved until that density is reached, whilst solutions of less density give off steam only until 20° B. is reached, the result being that steam, sulphuretted hydrogen, and calcium hydrate are formed simultaneously only when the boiling solution has a density of 20° B. and the density of the filtered liquid is preserved until the whole is evaporated to dryness and all the sulphur is given off. Miller and Opl found that this decomposition is partially accomplished on passing steam into the solution, and Hasenclever (this Journal, 1890, 182) has worked out this reaction on a practical scale. The results, however, were obtained with too large an expenditure of steam, and the author, in proceeding on the same lines, has arrived at a like conclusion. The solutions of calcium sulphhydrate are obtained by passing steam through a series of receptacles containing vat waste and water, and the author has treated such solutions with steam superheated to 140° to 160°, and under a pressure of 5 to 6 atmospheres. The sulphuretted hydrogen evolved was absorbed by milk of lime for the purpose of measurement. In one series of experiments 100 parts of sulphur were evolved as sulphuretted hydrogen at an expenditure of 678 parts of coal used for generating the steam. Calculations based on the thermo-chemical conditions of the reaction show that the heat required for the production of 1 part of sulphur should be furnished by 1·51

parts of steam, but as the heat supplied in this way has a low potential, the practical results necessarily fall much below the theoretical. More favourable results were obtained with an expenditure of 20 parts of steam or 3·1 parts of coal for 1 part of sulphur evolved, but the yield is still far below that required for profitable working. A further drawback is the length of time taken by the reaction, and its incompleteness, as the solutions are only partially denuded of sulphur. The deposited lime was found to consist of 72 per cent. of Ca(OH)<sub>2</sub>, 20 per cent. of CaCO<sub>3</sub>, 0·5 per cent. of CaSO<sub>4</sub>, and 7 per cent. of H<sub>2</sub>O, and was far inferior to ordinary slaked lime for the production of bleaching powder or for causticising soda liquors.—G. H. B.

*The Degree of Exhaustion of Gases.* K. W. Jurisch.  
Chem. Ind. **13**, 46—48.

WHEN a stream of gas is used for the purpose of carrying out a chemical reaction, and no foreign gas is mixed with it during the process, the degree of exhaustion (*Ausnutzungsgrad*) may be found from the amount of the active constituent contained in the in-coming and out-going streams respectively. Suppose, for example, that the carbonic acid from a limekiln is employed for the purpose of precipitating out sodium bicarbonate in the ammonia-soda process, or magnesium bicarbonate in the manufacture of magnesia, &c., or for the purpose of converting solid substances into carbonates or bicarbonates: the reaction takes place by an abstraction of carbonic acid from the stream of gas, so that it is poorer in carbonic acid after the process.

Let V denote the percentage (by volume) of carbonic acid originally present in the limekiln gas, and the percentage by v (again by volume) of carbonic acid in the gas after the reaction. The degree of exhaustion of the

carbonic acid (a factor of considerable importance in following the course of the process) is in many factories wrongly calculated on the assumption that the difference  $V - v$  represents the volume of the carbonic acid absorbed. On this assumption the degree of exhaustion would be simply given by the proportion—

$$V : V - v = 100 : n$$

$$\text{and } \therefore n = \frac{100(V - v)}{V}$$

This, however, is incorrect;  $v$  does not relate to the same volume as  $V$ ; for a reduction in the volume of the gas has been caused by the absorption of some of the carbonic acid.

Let us follow out more closely the process, beginning with 100 volumes of the limekiln gas. This contains  $V$  volumes of carbonic acid and  $(100 - V)$  volumes of inert gases which pass through the process unchanged. That these latter are of service in certain ways is true, but this does not concern us at present. A portion of the volume  $V$  of carbonic acid is absorbed: suppose  $x$  to denote the volume of carbonic acid left. The bulk of the original gas has now been reduced in the proportion of 100 to  $R$ , where—

$$R = 100 - V + x$$

The gas now contains only  $x$  volumes of carbonic acid to  $(100 - V)$  volumes of inert gases. If (as before) its volume-percentage of carbonic acid be denoted by  $v$ , then it may be stated to contain  $(100 - v)$  volumes of inert gases to  $v$  volumes of carbonic acid. These facts may be tabulated as below:—

Components.	In-going Gas.	Out-going Gas.	
	Volume.	Volume.	Percentage Composition by Volume.
Carbonic acid...	$V$	$x$	$v$
Inert gases.....	$100 - V$	$100 - V$	$100 - v$
Gas.....	100	$100 - V + x$	100

It is now evident that  $x$  can be calculated from the proportion—

$$100 : v = (100 - V + x) : x$$

$$\text{and } \therefore x = \frac{100 - V}{100 - v}$$

The reduction in volume is therefore in the ratio of 100 to  $R$ , where—

$$R = 100 - V + \frac{100 - V}{100 - v} \cdot v = 100 \cdot \frac{100 - V}{100 - v}$$

$R$  also represents the volume of the out-going gas as a percentage of that of the in-going gas.

If from the volume  $V$  of the carbonic acid originally present be subtracted the volume  $x$  of that which remains, there is obtained for the volume of the absorbed carbonic acid the expression—

$$V - x = V - \frac{100 - V}{100 - v} \cdot v = 100 \cdot \frac{V - v}{100 - v}$$

The degree of exhaustion ( $y$ ) of the carbonic acid in the form of a percentage of the amount employed, may then be found the proportion—

$$V : \frac{100(V - v)}{100 - v} = 100 : y$$

$$\text{and } \therefore y = 100 \cdot \frac{100(V - v)}{(100 - v)V}$$

This formula is clearly applicable to any other case in which a gas suffers partial absorption (e.g. for chlorine in the manufacture of chlorine products), but the volume of the inert gases must remain constant during the process.

The writer discusses the difference between the true value ( $y$ ) of the degree of exhaustion and the incorrect, but commonly-used, value ( $n$ ), and proceeds to find when this difference (i.e., the error) reaches its maximum. Calculations and tabulated results are given for dilute chlorine gas (Hunter-Deacon process, where  $V = 10$  per cent.), for strong Weldon gas ( $V = 50$  per cent.), for limekiln gases ( $V = 30$  per cent. of carbonic acid), and for strong carbonic acid such as is obtained by decomposing limestone with hydrochloric acid or by heating sodium bicarbonate ( $V = 90$  per cent.). For these the original paper must be referred to. It is shown that the error is greatest when the mixture is richest in the active constituent, and when the diminution in volume on account of the absorption is greatest.—D. E. J.

#### *On the Manufacture of Anhydrous Sulphuric Acid in France.* Chem. Ind. **13**, 48—49.

ANHYDROUS sulphuric acid is now made on the manufacturing scale in the Malétra works at Quevilly by Lunge's patent freezing process. The firm referred to holds the monopoly of the use of this process in France, and an account of the method of working it has been given by their chemists, Osterburger and Capelle (this Journal, 1890, 390—391).

The concentrated acid of commerce usually contains only 90—93 per cent. of pure acid, and as stronger acid is now frequently required for manufacturing purposes, it has latterly been produced (up to 97—98 per cent.) by concentration in platinum vessels, of which specimens were shown in Class 51 at the Paris Exhibition. It has now been found at the Malétra works that Lunge's freezing process can be satisfactorily carried out on the large scale. The commercial acid is first concentrated in platinum vessels, and it is advisable to bring it up to a strength of 96—97 per cent., for the mother-liquors from the process are then found to contain as much as 94—95 per cent. of  $\text{H}_2\text{SO}_4$ . The acid is cooled and transferred to a reservoir standing at a higher level than the "filling apparatus." This is made of iron, and is divided by vertical partitions into a number of compartments, each connected to a cell of the cooling apparatus beneath. (Each cell contains about  $12\frac{1}{2}$  kilos. of acid.) The cooling is effected by means of a solution of calcium chloride kept at a temperature of  $-20^\circ$  by an ice machine. In this solution are placed the iron cells.

In order to empty the cells containing the frozen acid, they are placed for a very short time in hot water, so as to loosen the crystals from the sides of the cells. The crystals are then separated from the strong mother-liquor, and placed in an enamelled reservoir, which is heated by steam or hot water. From this the melted acid is transferred directly to vessels suitable for transport.

No information is given respecting cost of manufacture. If this be not too high the process should be of great value in preparing concentrated acid suitable for the manufacture of nitroglycerin and celluloid, for dissolving indigo, purifying mineral oils, &c.—D. E. J.

See this Journal, 1890, 187—188.

#### *On the Compounds of the Alkali Metals with Ammonia.* H. W. Bakhuis-Roozchoom. Compt. Rend. **110**, 134—137.

A CRITICISM of the researches on sodammonium (Compt. Rend. **109**, 900) by Joannis, who found that the saturated solution of sodammonium in liquid ammonia had a vapour tension equal to the tension of dissociation of the solid sodammonium. The author declares this to be impossible except at one definite temperature  $C$ , the point of intersection of two distinct curves representing, (1), A D the variation of vapour pressure with temperature of a heterogeneous system composed of solid sodammonium, a solution of sodammonium in liquid ammonia, and ammonia gas. (2), B C the variation of vapour pressure with temperature of a system composed of sodium, solid sodammonium and ammonia gas intersect in a point.

He compares Joannis's observations with those of Lescœur (Recherches sur la dissociation des hydrates salins, Lille, 1888) on solutions of the hydrates  $\text{SrCl}_2 \cdot 6 \text{H}_2\text{O}$ , and  $\text{Na}_2\text{HPO}_4 \cdot 7 \text{H}_2\text{O}$ , and with his own researches on the hydrates of calcium chloride. References given for the author's general theory to Rec. Trav. Chim. Pays Bas., t. III.—VII and VIII., 1—146. He predicts that at a temperature above C. solid sodammonium will decompose into the system:—solid sodium + ammoniacal solution of sodammonium + ammonia.—P. J. H.

*On the Compounds of the Alkali Metals with Ammonia.*  
Joannis. Compt. Rend. 110, 238—240.

AN answer to the note by Roozeboom (see preceding abstract). The author confirms the results previously obtained at  $0^\circ$ : (1) by observing the vapour pressures with greater accuracy; (2) by showing that at that temperature the saturated solution of sodammonium in liquid ammonia cannot have a higher vapour tension than the solid sodammonium, since this solution does not act on metallic sodium to form the solid sodammonium. He, moreover, disproves the accuracy of Roozeboom's prediction that there exist two curves which intersect only in one point, by showing that sodammonium and its saturated solution possess identical vapour tensions between  $-10^\circ$  and  $+22.4^\circ$ .

The saturated solution was never found to decompose directly into ammonia and metallic sodium in the experiments made. But it is quite possible that this may occur at a temperature beyond the highest one as yet employed ( $+26^\circ$  with a pressure of 426 cm.).

Potassammonium and its saturated solution in liquid ammonia have the same vapour pressure at  $0^\circ$  and  $+8.41^\circ$ . (See also, for the theoretical discussion, Lescœur, Compt. Rend. 110, 275—277.)—P. J. H.

*On the Oxides of Manganese. 1st Part. The Psilomelanes and Wads.* A. Gorgeu. Compt. Rend. 110, 247—249.

FROM the examination of a certain number of wads and psilomelanes, the author concludes that these minerals are to be considered as true hydrated acid manganites, the composition of the most characteristic specimens being represented by the formula  $(3 \text{MnO}_2 \cdot \text{RO} + 1 \text{ to } 3 \text{H}_2\text{O})$ , where R stands for Mn, Ba, Ca, K, &c. They are extremely stable salts; repeated treatment with boiling dilute nitric acid only extracts a small quantity of the base from the finely powdered mineral.—P. J. H.

PATENTS.

*Improvements in and connected with the Obtainment of Chlorine and Sulphate of Lime.* A. Campbell, London, and W. Boyd, Glasgow. Eng. Pat. 3407, February 26, 1889. 6d.

AFTER the evolution of chlorine in the ordinary way by heating a mixture of hydrochloric acid, peroxide of manganese,

and water, a solution of chloride of manganese remains. The invention consists in obtaining a large additional quantity of chlorine from this chloride of manganese, and from a further quantity of chloride of manganese obtained by treating calcium chloride with sulphate of manganese, and in combining "the various processes in such a manner as to economically obtain a large aggregate production of chlorine whilst repeatedly reconverting and re-using the manganese and making sulphate of lime as a useful by-product."

Chloride of calcium from either the Weldon or Dunlop manganese recovery process, or obtained in any other suitable known way, is treated with a nearly equivalent quantity of sulphate of manganese, preferably keeping the mixture neutral or slightly acid so that the sulphate of lime which is precipitated may be as pure as possible. This precipitate is allowed to settle, and then is filtered, washed, and dried.

Of the solution of chloride of manganese thus obtained, about 60—70 per cent. are mixed with the neutralised residual liquor from ordinary chlorine stills and is worked up for the recovery of the manganese it contains either by the Weldon or Dunlop process. "Instead of using simple milk of lime in the Weldon re-oxidising process, we prefer to mix the lime after slaking in the solution of chloride of calcium, in which it dissolves to some extent, thereby obtaining a thinner liquor or one with less water for a given quantity of lime, and diminishing the quantity of fuel required for concentrating solutions. Or we may use milk of lime formed with washings from other parts of the processes."

The remaining 30—40 per cent. of chloride of manganese solution is concentrated to a suitable density such as  $60^\circ$ — $70^\circ$  Tw., and after mixing with an equivalent proportion of mud which has been washed free from calcium compounds, is run into a still where it is heated with a quantity of sulphuric acid equivalent to the chlorine present; all or nearly all the chlorine is liberated, and sulphate of manganese is left in solution. This sulphate of manganese is neutralised with washed peroxide of manganese mud, and after settling, the clear liquor is used for treating chloride of calcium as above described.

In the operation by which chlorine is liberated by heating the mixture of sulphuric acid and chloride of manganese with manganese mud, it is necessary that the mud and chloride should be freed, as far as possible, from calcium compounds. To effect this, mud from the Weldon or Dunlop processes is treated in a chlorine still with an excess of hydrochloric acid sufficient to dissolve all the calcium present. After driving off the chlorine, as in the ordinary process, the liquor is drawn off, allowed to settle, and may then be used in the manganese-recovery parts of the processes, or may be mixed with sulphate of manganese to form sulphate of calcium. By a modification of this method of working instead of running the mud containing calcium into the chlorine still, it may be treated with chloride of manganese liquor sufficient to convert most of the lime present into chloride of calcium; the mud after settling is then treated with the residuary liquor from the stills, so that the free acid remaining in such liquor may convert any remaining lime into chloride of calcium. After drawing off the clear liquor the remaining mud is filtered, pressed, and washed to render it practically free from calcium chloride; the weak washings from the precipitated sulphate of calcium which contain chloride of manganese may be advantageously used for washing the mud. The manganese cakes obtained are then mixed with a solution of chloride of manganese and run into a still along with sulphuric acid. The peroxide is preferably used in excess, so that the residual liquid is neutral, and this excess can, after expelling the chlorine, be separated by settling or filtering and added to fresh material.

Impurities which tend to accumulate are from time to time separated by precipitation from a suitable proportion of the residual liquor of the stills in which the first portion of the chlorine is evolved, and the purified liquor is then returned to the remainder.—H. S. P.

*An Improved Process and Apparatus for the Manufacture and Transport of Liquid Chlorine.* J. B. Hamay, Loch Long. Eng. Pat. 4037, March 7, 1889. 8d.

The inventor produces "gaseous chlorine in any known manner under a little pressure, sufficient to cause it to bubble through water contained and agitated in a series of vessels which are kept cooled to about freezing point. In each of these vessels, through which the chlorine passes successively, a portion of the chlorine forms a combination with water, producing a crystalline deposit." This deposit forms most rapidly in the first vessel, and more slowly in succeeding ones. When a sufficient amount of deposit has formed in the first vessel, it is disconnected, and the second vessel then becomes the first in the series, and so on. The crystalline deposit is removed and freed from water by squeezing, and then charged into a strong vessel with a funnel-shaped bottom, having a small outlet. On closing this vessel and applying heat externally, the chlorine separates from the water with which it was combined, and subsides in the liquid condition to the bottom, while the water floats above it. "To the bottom of the separating vessel (preferably with an intermediate vessel which may be charged with sulphuric acid to trap any water accompanying the chlorine) is connected one of the holders in which the liquid chlorine is charged for transport." The holder is a thin, strong, steel tube, closed at one end, and fitted at the other end with a projecting boss, into which a plug can be screwed. This plug, before the holder is charged, is contained in a tube attached to the boss, this tube being connected to the separating vessel by a lateral branch provided with a valve. The valve being opened, the liquid chlorine passes into the holder; the plug is then screwed home, and the holder detached. When it is desired to use part of the chlorine contained in the holder, a branch tube, similar to that employed for charging, may be connected to the boss, and the plug can be unscrewed. Drawings of the apparatus accompany the specification.

—H. S. P.

*Improvements in the Manufacture of Anhydrous Chloride of Magnesium and in the Production of Chlorine therefrom.* W. L. Wise, London. From Solvay and Co., Brussels, Belgium. Eng. Pat. 4417, March 13, 1889. 6d.

A common feature in all the processes for obtaining chlorine from magnesium chloride is the heating in a current of air of a mixture of chloride of magnesium and magnesia in the solid state. The chief difficulty in these processes is caused by the pulverulent condition assumed by the material during its decomposition; further, a mass of magnesia is treated which merely serves as a support and does not itself yield chlorine. By this invention these disadvantages are overcome by decomposing anhydrous chloride of magnesium in the fused state by a current of hot air. The process comprises two stages; 1, the preparation of anhydrous magnesium chloride; 2, the production therefrom of chlorine.

The anhydrous magnesium chloride is prepared from the magnesium chloride of commerce, which is a concentrated solution, or from the crystallised salt  $MgCl_2 \cdot 6H_2O$ . By heating this salt at a temperature below  $120^\circ C$ . it can be brought to contain about 80 per cent. of anhydrous salt without fusing and without giving off hydrochloric acid. When once brought to this condition it will stand a still higher temperature without fusing or giving off  $HCl$ , and almost the whole of the water of crystallization can be expelled; but during the first part of this operation the point of fusion is very nearly reached so that the desiccation requires considerable care, and in order to render the operation more practicable, the following process is adopted: A hot concentrated solution of hydrated magnesium chloride is mixed with 50 per cent. of anhydrous  $MgCl_2$ . On cooling this gives a compact mass which is broken into pieces and heated in a vertical and continuous action apparatus by a current of hot air. In this way it can be heated to  $300^\circ$  or  $400^\circ C$ . without melting, whilst the original salt would melt at  $115^\circ C$ . The anhydrous chloride may be also mixed with the hydrated crystallized salt instead of with a solution

of it. The current of air employed is first dried by suitable means such as sulphuric acid or chloride of calcium, and it may be made to circulate through the apparatus so as to be used over and over again; as it merely acts as a vehicle for carrying off water, any other suitable gas may be used instead of air if required.

To obtain chlorine from the anhydrous magnesium chloride this salt is fused and subjected at a red heat to the action of a current of air. It is considered advantageous to melt the magnesium chloride in a crucible or in a vessel resembling a Bessemer converter, either by heating from the outside or by the heat supplied by the current of air which enters by a lower tuyere or a "bubbling tube." In any case the current should not enter through the bottom of the vessel as a zone of quiet fusion should be left underneath the air inlet. The magnesia formed by the action of the air on the molten chloride is dense and collects on the bottom of the vessel whence it can be removed by scooping it out or drawing it off through a tap hole. The magnesia thus obtained is contaminated with a small quantity of magnesium chloride from which, if desired, it may readily be freed by washing.

The current of chlorine obtained contains 15 to 20 per cent. of chlorine, and this percentage is maintained invariable from the beginning to the end of the operation.—H. S. P.

*Improvements in the Treatment of Black Ash and Alkali Waste to obtain Sulphuretted Hydrogen, Sulphur, and Cement, and in Apparatus employed therein.* James Hargreaves, T. Robinson, and John Hargreaves, Widnes. Eng. Pat. 6968, April 26, 1889. 8d.

The apparatus, which is made of iron, is a combination of black-ash lixiviating tanks and of carbonators, the two

Fig. 1.

Fig. 2.

operations being carried out in the one vessel. The black ash is supported on movable perforated grids, by which means both the lixiviation and the carbonation are facilitated. In Figs. 1 and 2 *a* is the vessel, *b* the charging door, *c* the discharging door, *d* inlet for gas, and *e* exit for gas, *f, f'* grids supported on bars *g*, which work in grooves *h*; the grids can be raised or lowered by the chains *j*. Instead of grids perforated plates may be employed.

The vessels can also be arranged in varying series, or entirely isolated. Sufficient  $\text{Na}_2\text{O}$ , from about  $1\frac{1}{2}$  to  $2\frac{1}{2}$  per cent., is left in the black ash to dissolve out at the proper time the various sulphur compounds. Carbonic acid at a pressure of about 10 lb. per square inch is forced in through the alkali waste, which is kept moist. When strong sulphuretted hydrogen is required the inert gases are allowed to escape into the atmosphere, when, on the other hand, dilute sulphuretted hydrogen is to be utilised for the production of sulphur or sulphurous acid, then this and the air to be supplied to it are first heated before combination. The heat evolved in the act of combustion is employed for heating the gases as above to a temperature of about  $400^\circ\text{F}$ . Heated air is now blown in to oxidise the residual sulphur compounds; then water added and steam injected to heat the paste thus formed. The sodium carbonate is causticised and the sulphur dissolved out. The residual carbonate of lime is mixed with clay and converted into cement.—S. G. R.

#### *Improvements in Apparatus for Treating Gases by Liquids.*

E. Edwards, London.—From G. Lunge, Zurich, Switzerland, and L. Rohrmann, Kranschwitz, Prussia. Eng. Pat. 6989, April 26, 1889. 8d.

THE improvements relate to the "plate columns" already described in this Journal, 1886, 468; 1887, 538, 584, and 597, and consist in making the "jacket surrounding the plate column" of metal, stone, or other suitable material. The perforated plates are made of earthenware and the annular supports or brackets are either made of one solid piece or in segments and have supporting webs or ribs, the segments being butt- or lap-jointed or provided with grooves to be filled up by lead or other suitable substance.

—O. H.

*Improvements relating to the Recovery of Soda from Slags containing the same.* "The Alkaline Reduction Syndicate, Limited," and A. B. Cunningham, Hebburn-on-Tyne. Eng. Pat. 7733, May 8, 1889. 4d.

See under X., page 519.

*Improvements in the Manufacture of Soda Alum.* E. Augé, Montpellier, France. Eng. Pat. 16,711, October 22, 1889. 6d.

To a solution of sulphate of alumina in slight excess sulphate of soda in the equivalent proportion and in the anhydrous condition is added and the solution concentrated by steam until it attains a density of from 1.38 to 1.45. It is then poured out upon tables and allowed to remain until it becomes pasty, when it is carefully spread out upon inclined tables and allowed to crystallise, the temperature being kept at about  $60^\circ\text{F}$ . In the course of two or three days a further change takes place in the crystals with the separation of more mother-liquor, which removes with it most of the iron and other remaining impurities. The alum is washed in a centrifugal machine and kept in a cool place. The inventor also points out that soda alum thus kept is not efflorescent, that its solubility is about one-third of that usually given, and that a solution of soda alum which has been boiled will still crystallise.—S. G. R.

*Processes for the Production of Chlorine and of obtaining Concentrated Gaseous Hydrochloric Acid for that Purpose.* P. de Wilde and A. Reyckler, Brussels, Belgium. Eng. Pat. 17,272, October 31, 1889. 6d.

In this patent a number of methods are described for obtaining chlorine by passing first gaseous hydrochloric acid

and then air over certain substances heated to redness in a system of cylinders of cast-iron or earthenware and communicating with each other like the cylinders in the sulphate process of Hargreaves. The gas given off when the air is being passed through the cylinders contains from 20 to 25 per cent. of chlorine, and may be directly used for making hypochlorites and chlorates. Instead of using hydrochloric acid and then air a mixture of these gases such as is obtained from sulphate furnaces may be used. In this case the operation becomes continuous, but the gases which come from the cylinders are less rich in chlorine and contain hydrochloric acid and steam which have to be removed by known processes before the chlorine can be used for making hypochlorites and chlorates. The following are the substances mentioned in the patent to be treated as above described:—

1. A calcined mixture of sulphate of magnesium and of magnesia, which is obtained as a residue of "solid porous consistency" from a process patented in France and Germany by one of the patentees. At a dark red heat gaseous hydrochloric acid acting on this mixture converts it into a mixture of magnesium sulphate, magnesium chloride, and magnesium oxychloride. On passing heated air over the last mixture the chloride and oxychloride are decomposed, chlorine is liberated, and a mixture of magnesium sulphate and of magnesia is regenerated.

2. A mixture of magnesium sulphate and manganite of magnesium ( $\text{Mn}_2\text{Mg}_3\text{O}_7$ ), which is made by heating in a muffle furnace equivalent quantities of magnesium sulphate, magnesium chloride, and manganese chloride, all three hydrated. The action of the hydrochloric acid gas on this mixture is as follows:—

On passing a current of dry air over this mixture of substances at a dull red heat chlorine is disengaged, and the mixture of magnesium sulphate and magnesium manganite is regenerated as follows:—

3. A mixture of magnesium sulphate and intermediate oxide of manganese ( $\text{Mn}_2\text{O}_3$ ) obtained by calcining a mixture of magnesium sulphate and manganese chloride. Magnesium chloride alone and manganese chloride alone, or a mixture of the two, fuse before reaching a dull red heat, but the presence of magnesium sulphate prevents this and facilitates the decomposing action of the air.

4. In the processes above referred to, instead of using magnesium sulphate, the sulphate of an alkaline earth or a not readily fusible phosphate, arseniate, borate, or silicate of magnesium or of an alkaline earth, or alumina or silicate of aluminium, or sand or any other not readily fusible substance, which has no action on magnesia, manganite of magnesium, or intermediate oxide of manganese, may be used.

5. Further, a claim is made for "the addition of sulphate of magnesium or of sulphate of an alkaline earth to chlorides of metals to promote their decomposition by dry air at high temperature with liberation of chlorine."

The gaseous hydrochloric acid used in these operations alternately with air should be as concentrated as possible. It is taken from the pan of a sulphate furnace, or obtained by treating commercial hydrochloric acid with sulphuric acid of 60 B. The two acids are simultaneously introduced into the top of a lead tower four or five metres high filled with coke. Gaseous hydrochloric acid is given off and dilute sulphuric acid is drawn off at the bottom of the tower and can be again concentrated.—H. S. P.

*Improvements in the Manufacture of Anhydrous Barium Oxides.* H. H. Leigh, London. From T. de Brochoeki, Paris, France. Eng. Pat. 1300, January 24, 1890. 4d.

Barium sulphate is converted into the chloride by roasting with calcium chloride "either alone or in combination with coal and calcium carbonate," and the mass is extracted with

water. The barium is then precipitated as carbonate with ammonium carbonate. The precipitate is made up into balls or briquettes with coal dust and calcined, barium oxide being the result which can now be readily converted into the dioxide, hydrate, or other compounds. During the final calcination the muffle may be kept filled with some neutral gas, to prevent the passage inwards of carbonic acid from the furnace gases and from the air.—S. G. R.

*Improvements in and connected with Saturators for Sulphate of Ammonia Plant.* G. Kennedy, East Ham. Eng. Pat. 1653, January 30, 1890. 6d.

THE saturators, instead of being made of wood lined with lead, are entirely of lead or of an alloy of lead and antimony, and are cast preferably in only two pieces. In order to

support the curtain C, which is the part most apt to fail in the saturators of ordinary construction, an arched rib *c* is cast solid with C and the side walls *t t*, and this may be also further strengthened by a bead *c'*. The cover *R* is either dome- or cone-shaped. *H* is a flanged aperture, and bolted to it is *h*, which can either serve as a sulphuretted hydrogen exit pipe or may be entirely removed and the aperture used as a manhole. The joint at *N* is also patented. *N*, which is cast with the saturator, is furnished with a packing ring, *n*, of asbestos. The inlet pipe for the ammonia, *p*, is made of lead, and is expanded over the asbestos packing ring. To this is applied the flanged supply pipe *P*, which can be readily secured and disconnected by means of bolts. *S* is the body and *ff f* are stiffening ribs.—S. G. R.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*Cements which withstand Frost.* Bernhofer. *Thonindustrie Zeit.* 1890, 47.

THE author observed that mixtures of (a) 1 litre of Portland cement, 3 litres of river sand, and (b) 1 litre of lime cement and 3 litres of river sand, mixed with a solution of 1 kilo. of crystallised soda in 2 litres of water, when exposed to a temperature of  $-12.5^{\circ}$ , are not in the least altered in their adhesive properties.—J. B. C.

*Action of Boiling Water on Cement.* L. Erdmenger. *Thonindustrie Zeit.* 1890, 62.

GOOD Portland cement should after hardening withstand the action of boiling water; but water under a steam pressure equivalent to 10–40 atmospheres reduces its hardness. Mixtures of one part of cement and three parts of sand

when hardened can be subjected to the action of boiling water without undergoing change, but when considerable quantities of magnesia are present in the cement it does not withstand the continued action of boiling water, but gradually becomes soft.—J. B. C.

*Henry's Slag Cement.* H. Le Chatelier. *Bull. Soc. d'Encouragement l'Ind. Nat.* 1890, 26–28.

THIS is a report made to the *Société d'Encouragement* on behalf of the *Comité des Arts Chimiques*, and refers to an improved method of manufacturing hydraulic slag cements introduced into France by Henry. The manufacture of a cement of good quality from slags presents this difficulty that whilst only vitreous slags have any puzzolanic properties whatever, the most active varieties are those which contain the largest percentage of base. All attempts, however, hitherto made to increase the percentage of lime and alumina resulted in the formation of a crystalline slag which in virtue of its structure is totally inert.

Henry has overcome this difficulty by running the highly basic slag into water; the rapid cooling preserves the active amorphous structure; the slag is then finely crushed and mixed with a certain proportion of slaked lime. The product is not much inferior to Portland cement, and may be further improved by the addition of a few per cent. of precipitated silica.—S. B. A. A.

## PATENTS.

*A Process for Producing Mono-Carbonate of Calcium.* F. Mühlenbrueh, Magdeburg, Germany. Eng. Pat. 4195, March 9, 1889. 6d.

POWDERED calcium carbonate is mixed with finely ground quicklime in the proportion of 4.5 parts of the former to six parts of the latter and the mixture is stirred up with water; it is then exposed to the influence of carbonic acid gas or to the atmosphere (which always contains carbonic acid) whereby a solid and entirely homogeneous mono-carbonate of calcium is produced. Other materials such as marble chips, sand, colouring matters, &c., may be incorporated in the mixture. The substance produced may be used as artificial limestone, marble, for wall-compo, wall-covering or mortar, or it may be formed into artificial stone blocks.—H. S. P.

*An Improved Mode of Treating Hemp, Flax, Jute, and other Fibres, and Employing such Materials for the Manufacture of Tiles, Slabs, Cisterns, Boats, and other Articles or Structures.* B. A. Weatherdon, London. From T. A. Compere, Naples, Italy. Eng. Pat. 7058, April 27, 1889. 6d.

THE fibres are cut (by any suitable cutting machine) and boiled four to six hours in a strong solution of lime by steam at a pressure of from 20 to 40 lb. to the square inch. After being thoroughly washed, the material is passed to a pulping machine, where it is treated with alum about 7 to 14 lb. to the cwt., and in some cases with animal size, and in others with vegetable or other oils. From the pulping machine it is run into receiving or storing tanks, fitted with machinery for keeping the pulp in agitation, and whilst therein it can be dyed, if required. Now the pulp fibre is pumped into vats, and from thence into wire moulds, to be formed into slabs, blocks, &c., the liquor being extracted by suitable pressure. The slabs, blocks, &c. are brought into the drying-room, and when dry passed through solid steel rollers 4 to 12 times, steeped in a warm solution of alum, and again subjected to hydraulic pressure. Then they are brought into a bath of vegetable or other oil for four to six hours, and again pressed and steam-rolled as many times as necessary. To finish the process they are dried in hot air, and in some cases passed through the rollers once more.—H. S.

*An Improved Method of making Cement from Chalk, Marls, and Argillaceous Limestones, and of Utilising Poor Clays for the Purpose of making Cement, and Apparatus therefor.* G. P. Gildea, Ipswich. Eng. Pat. 8145, May 16, 1889. 6d.

THE patentee, having observed that the clay commonly used in the manufacture of Portland cement contains more organic matter than is generally present in cement stones and marls, adds to such materials, and thoroughly incorporates with them by the agency of hot water, 2—2½ per cent. of some oil or fat, allowing the mixture to rest for about a week, in order that the fatty matter may exert a "solvent influence" upon the clay. At the end of this time the slurry is dried and burnt as usual, producing, it is claimed, a better cement than would otherwise be obtained. The use of the fat is not claimed as a combustible, the quantity being inconsiderable, and the principle being already known.

—B. B.

*Improvements in Machines for the Manufacture of Bricks and Briquettes.* N. Procter, Leeds; A. Middleton, Ben Rhydding; C. E. Fraser and H. M. Carter, Leeds. Eng. Pat. 11,403, July 16, 1889. 6d.

HEAT being necessary and employed for moulding briquettes for fuel, the materials are apt to become unduly hot during their passage down the hopper by which they are fed into the moulding machine. The patentees insulate the hopper from the machine by means of an intermediate non-conducting piece of wood or similar material, and also provide a plate cutting off the connexion between the two, which plate is withdrawn periodically to allow the entrance of the materials into the machine by a rack and pinion apparatus actuated by a cam.—B. B.

## X.—METALLURGY.

*Zinc and Lead in Burnt Gases from Blast Furnaces.* A. Vita. Zeits. f. angew. Chem. 1890, 69—71.

WHERE ores are used containing zinc and lead, the oxides of these metals are contained in the burnt gases. The present paper concerns itself with the quantities of the oxides contained in the burnt gases, when the gases have before combustion undergone a certain amount of "purification." Such "purification" was effected by passing through a Maccos's ascension pipe and five tanks, each divided into two parts. Each tank was 14 metres high and had a base of 2 × 3 metres. A distributing channel of 1.5 × 2 metres section conducted the gases thence to the Cowper apparatus. The results obtained show that even after the passage of the gases through this system a notable quantity of zinc and lead still escapes.

Samples were aspirated from the gases after passing the Cowper apparatus, and were passed through five wash-bottles containing respectively water, hydrochloric acid, nitric acid, bromine in hydrochloric acid, and alcohol, the last-named being intended to absorb any bromine vapour which might pass over.

On six different days 1,202 litres of burnt gases were aspirated and examined. Samples of the unburnt gases were also examined. From the quantity and composition of the materials fed into the furnace in each day of 24 hours, and from the composition of the gases before combustion and after, it was calculated that for every ton of pig iron produced the burnt gases carried off 3.89 kilos. of zinc—that is, so much zinc is totally lost. The zinc recovered for every ton of iron produced was 15 kilos., so that the loss is 27 per cent. of the recovered zinc.

The loss of lead is naturally very much smaller than that of zinc. For every ton of iron produced the flue-dust contained 3.9 kilos. of lead, and the amount lost was 360 grms. Besides the losses here considered, there are other sources of loss. For instance, the furnace-slag contains zinc; loss is sustained at the furnace mouth; the masonry of the furnace takes up zinc.—T. L. B.

*The Nature of Amalgams.* W. L. Dudley. Address to the American Association for the Advancement of Science. August 1889.

THE author at the outset remarks upon the small amount of work which has been done on this subject. After a short account of early knowledge of amalgams he proceeds to more recent investigations. It was formerly supposed that the production of amalgams was attended with an evolution of heat, but Demachy in 1774 proved that a reduction of temperature occurred in the amalgamation of tin, lead and bismuth. At a later date J. Regnault found that amalgamation caused metals to change their place in the electro-chemical series. When heat is absorbed the amalgam is more electro-positive than the metal, when heat is evolved it becomes less electro-positive. Berthelot in 1880 examined the constitution of potassium and sodium amalgams by measuring the heat evolved in their formation. He obtained evidence of the existence of the alloys  $\text{Hg}_{12}\text{K}$  and  $\text{Hg}_5\text{Na}$ . He also found that the relative affinities of the alkali metals in these alloys were reversed, thus accounting for the displacement of potassium by sodium when sodium amalgam is added to a solution of potassium hydrate. Indications of the existence of the amalgams  $\text{Hg}_4\text{K}$ ,  $\text{Hg}_4\text{Na}$ , and  $\text{Hg}_7\text{Na}$  were also obtained. The electric conductivity of amalgams has been investigated by Mattiessen and Vogt, Sabine, Weber and others. Weber's researches were confined to the amalgams of tin, lead, bismuth and cadmium. It was found that a small quantity of impurity in mercury considerably reduces the resistance of the mercury. The conductivity of the amalgam is not the mean of the conductivities of its constituents. Bismuth and lead amalgams conduct better than either of their constituents. In 1850 Joule prepared amalgams of iron and copper by electrolysis, removing excess of mercury by submitting the alloys to a pressure of 60 tons. The iron alloy consisted of 100 parts of mercury to 103.2 parts of iron. The iron was found to retain its magnetic properties. The copper amalgam consisted of mercury, 100 parts; copper, 27.76 parts, and had a sp. gr. 13.17. A silver alloy,  $\text{AgHg}$ , and amalgams of platinum, zinc, lead and tin were also prepared. Considerable contraction took place in the formation of the copper, silver and zinc amalgams, but little with those of platinum and lead. Joule tried to amalgamate hydrogen by developing it at a low temperature (0° F.) in mercury. The specific gravity of solid mercury calculated from the copper amalgam was found by Joule to be 14.985. The latest direct determination gives 14.931.

De Souza, in 1875, examined the effect of heat upon amalgams. Gold amalgam had a composition  $\text{Au}_3\text{Hg}$ , after heating to the temperature of boiling diphenylamine, but became  $\text{Au}_9\text{Hg}$  when heated to the temperature of boiling mercury. Silver amalgam became  $\text{Ag}_3\text{Hg}$  in the vapour of boiling mercury,  $\text{Ag}_2\text{Hg}$  in that of diphenylamine. Copper formed the compound  $\text{Cu}_2\text{Hg}$  in vapour of boiling sulphur, but  $\text{Cu}_3\text{Hg}$  in boiling mercury and diphenylamine. At a later date Merz and Weith repeated de Souza's experiments and found that amalgams were gradually decomposed at the above temperatures, the small amount of mercury left being retained by mechanical attraction. The author has repeated these experiments on gold amalgam, and finds that it has a composition  $\text{Au}_3\text{Hg}$  when heated to the temperature of boiling mercury. He considers that the gases, hydrogen and nitrogen, used by the last experimenters to remove mercury may have caused the decomposition of their amalgams, especially as they observed that in the case of potassium and sodium amalgams the mercury was more rapidly removed in hydrogen than in nitrogen.

With regard to the melting points of amalgams, Merz and Weith found that they bore no relation to the composition of the alloy; for example, a sodium amalgam containing 3 per cent. of sodium, melted at 152°—160°; with 4.7 per cent. of sodium the melting point was 305°—315°, the maximum, a further increase of sodium lowering the melting point. The chemical activity of some metals is increased by amalgamation, whilst that of others is decreased. Thus Wanklyn and Chapman found that magnesium amalgam oxidised rapidly when exposed to air and decomposed water violently. Aluminium amalgam behaves in the same manner, whilst potassium and sodium are less energetic when amal-

gated than in the free state. The author gives a very full account of ammonium amalgam. The most conclusive experiments in proof of its existence are those of Davy, Landolt, and Routledge, showing that the amalgam contains ammonia and hydrogen in the proportion of 2 vols. of the former to 1 of the latter. The last observer examined the change in volume of the amalgam under different pressures, and found that the compressibility was due to gases resulting from the decomposition of the amalgam. In addition to the above mentioned experiment of Joule on hydrogen amalgam the author quotes that of Doebereiner and Loew, in which a zinc amalgam containing 5 per cent. of zinc was agitated with a 10 per cent. solution of platine chloride, the mixture being kept cool. The zinc amalgam swelled up considerably, and continued to evolve hydrogen until it was entirely decomposed. The hydrogenium amalgam thus prepared was dried by filter paper. On exposure in thin layers to the air, the temperature rose considerably and aqueous vapour was evolved.

The specific heat of alloys was shown by Regnault to be the mean of the specific heats of their constituent, but the amalgams of cadmium, tin, lead, and bismuth are exceptions. Wiedemann considers that these alloys are mixtures of a solid and a fluid, the proportions of which vary with the temperature. Two amalgams,  $\text{SnHg}$  and  $\text{Sn}_2\text{Hg}$ , were examined at  $128^\circ$  and  $164^\circ$  respectively, and behaved like lead alloys in the neighbourhood of their so-called second melting points, but the temperature did not remain constant for any appreciable time.

The above researches prove that amalgams are unstable chemical compounds, the absorption of heat on the amalgamation of some metals being probably due to the solution of the amalgam in the excess of mercury. The greater portion of an amalgam in excess of mercury is, however, only in suspension, since the author has found that the upper portion of at 0.1 per cent. gold amalgam, which had remained in a glass cylinder for some months, contained only 0.0683 per cent. of gold. After filtration through boxwood it contained only 0.0601 per cent. The effect of excess of mercury may be to reduce the amalgam to crystal units instead of breaking up the molecule as in ordinary solution. These crystal units would pass through the pores of chamois leather, but not through those of boxwood. The following index to literature on amalgams is given:—

*The Use of Fluorspar in Metallurgy.* Foehr. Chem. Zeit. **14**, 253—254.

THE comparatively high price of fluorspar has excluded its use in iron smelting. It has, however, proved itself to be an energetic flux in the blast furnace, being introduced as powder through the tuyere holes. It plays an important part in the production of ferro-silicon. This compound can be produced in an ordinary blast furnace from any siliceous iron ore. It only requires a very basic slag and the addition of fluorspar. The latter greatly promotes the reduction of the silicon, probably forming silicon fluoride, which is reduced by the furnace gases or directly by the coke. The author considers it not unlikely that, owing to the enormous increase in the price of coke, fluorspar may be introduced as a fuel-saving flux, as the smallest addition of it effects the formation of dark grey iron.

The peculiar property of fluorspar in readily bringing about the reduction of the most different substances makes it a valuable flux in the production of spiegeleisen. Manganese fluoride is probably first formed and undergoes reduction at the expense of the carbon. It appears indispensable to form a highly basic fluoride slag in the production of a rich ferro-manganese. The property of fluorspar to combine with phosphorus in the slag plays an important part in dephosphorising pig iron in Krupp's basic cupola process.

A small quantity of fluorspar is now added in the Thomas and Bessemer processes, in order to reduce and concentrate the amount of slag and produce a better yield of metal. With an acid lining, fluorspar must be used with caution, as it is apt to corrode the lining. In puddling, the Martin's and other steel-making processes, a small quantity of fluorspar is said to be used as flux.

In the pig-iron manufacture the case is different and the much cheaper limestone is to be preferred. In melting down the pigs for casting, the addition of fluorspar effects the introduction of silicon into the iron and assists in eliminating phosphorus and sulphur. Too large a quantity of fluorspar is more deleterious than beneficial, probably in consequence of the manganese being retained in the iron. For 100 kilos. of pig iron only  $\frac{1}{3}$ — $\frac{1}{2}$  kilo. of fluorspar should be used. The addition of fluorspar is particularly noticeable in the newer cupolas, especially in that of Herbert's. For pure qualities of pig iron, such as Swedish charcoal pig, fluorspar is essential. Fluorspar assists greatly in fluxing heavy spar.—J. B. C.

*Experiments with Ferro-silicon.* Jüngst. Zeits. f. Berg.-Hütten-u-Salinenw, 1890, 1.

THESE experiments have shown that the presence of silicon increases the tenacity of cast iron. Whereas the best classes of grey cast iron resist a bending strain of 25 kilos., and have a tenacity of 14 kilos. per sq. cm., the addition of ferro-silicon imparts a tenacity of 37 and 23 kilos. respectively. The use of ferro-silicon may be introduced with success if the approximate chemical composition of the cast iron be known. It is important that ferro-silicon should not be added indiscriminately to grey cast iron containing silicon; but that the amount of alloy should be predetermined mainly by the quantity of combined carbon and graphite present. In addition to the composition of the cast iron, the structure has also an influence on the tenacity. The greatest tenacity may be attained both by re-melting grey cast iron as well as melting it down with ferro-silicon. The success of re-melting grey cast iron in this way depends on a variety of conditions, whereas the use of white iron with ferro-silicon is a much more certain operation, although the present price of ferro-silicon has precluded its extended introduction in Germany. With regard to the best quality of ferro-silicon, the experiments at the Gleiwitz works, with a medium quality containing 10.38 per cent. of silicium, gave the best results. A 5.32 per cent. ferro-silicon increased the tenacity, but was less satisfactory in other respects. A rich ferro-silicon, on account of the small quantity added, is liable to produce an irregular casting, although the tenacity is largely increased. The presence of manganese or phosphorus up to 1 per cent. and sulphur to the extent of .16 per cent. has no injurious effect. It must, however, be observed that in selecting the qualities of iron for castings the above quantities are not exceeded.

—J. B. C.

*On the Role of Certain Foreign Bodies in Iron and Steel.* F. Osmond. Compt. Rend. 110, 242—245.

It is known that iron exists under two states, which the author calls  $\alpha$  and  $\beta$ . When electrolytic iron containing only 0.08 per cent. of carbon is cooled down, an evolution of heat takes place at two points. The first at 855°, which he calls  $a_3^*$  is very marked; the second  $a_2$ , less marked, attains its maximum about 730°.

$a_3$  is due to the transformation of the allotropic form of iron  $\beta$  into the form  $\alpha$ ;  $a_2$  might be looked on as due to another transformation, but seems to be merely a retardation of the first taking place in those parts of the metal which contain most carbon. The carbon itself, passing from the state of *carbone de trempe* (hardening carbon) to *carbone de recuit* (annealing carbon) in iron containing this element, determines a third evolution of heat at a point  $a_1$ , which was discovered by Barrett under the name of *recalcescence*.

The position of these critical points is not fixed, but varies with the composition of the metal; as the percentage of carbon increases  $a_3$  is lowered, and finally coincides with  $a_2$ ; and then  $a_3$  and  $a_2$  united become lower still, and finally coincide with  $a_1$ , which has become slightly raised.

The action of certain bodies on these phenomena has been already studied by the author (Compt. Rend. 103, 743 and 1135; 104, 985 and 1800), and details are now given with regard to the influence of Bo, Ni, Cu, Si, As, and W.

1. *Boron* (specimen prepared by Professor Roberts Austen) acts like carbon; the evolution of heat normally taking place at  $a_3$ , occurred partly at 815°—805°, partly at 735°—725°, i.e.,  $a_2$ .

2. *Nickel*. The specimen contained C = .34 per cent. Ni 5.97 per cent., Mn "traces." With a steel containing the same percentage of C, but no Ni,  $a_3$  and  $a_2$  would coincide. In this case  $a_3$ ,  $a_2$ , and  $a_1$  all coincide at a single point, 660°—640°, a temperature below the normal point of recalcescence.

\* The author uses an extension of Tchernoff's notation of the lowest temperature at which the steel can be hardened, by the letter  $a$ .

Hopkinson has shown by another method that for a hard steel with 25 per cent. Ni, the critical point is below 0°. Manganese acts like nickel.

3. *Copper*. Three specimens prepared by Messrs. Ball and Wingham, given by Professor Roberts Austen:—

	I.	II.	III.
Cu .....	Per Cent. 0.847	Per Cent. 4.19	Per Cent. 4.44
C .....	0.102	0.183	0.10

As the percentage of Cu is increased,  $a_3$  and  $a_1$  are both lowered.

With II. and III.  $a_3$  coincides with  $a_2$  at a point 730°—720°, and  $a_1$  is lowered to 625°—620°. Hence copper acts like carbon, but much less energetically, the action of 4 per cent. Cu being equal to that given by 0.25 to 0.30 of C. Copper acts on the point of recalcescence in the same way as nickel and manganese.

4. *Silicon* (five specimens prepared and given by Mr. R. A. Hadfield, containing 0.20 to 4.40 per cent. Si). As the percentage of silicon increases the quantity of heat evolved at the point  $a_3$  diminishes, and is sensibly nil when 2 per cent. is reached. Contrary to what occurs with the previous elements, this heat is not evolved at  $a_2$  or any other point. Hence it follows that silicon prevents the allotropic transformation of the iron, which remains in the state  $\alpha$ . The evolution at  $a_3$  is unchanged in quantity, but  $a_2$  is lowered from 730°—720° to 710°—700°, and  $a_1$  is raised from 660°—650° to 710°—700°.

5. *Arsenic* (four specimens prepared by Messrs. Harbord and Tucker, given by Professor Roberts Austen). As the proportion of arsenic increases from "traces" to 0.55 per cent., the point  $a_3$  is raised, but the heat given out is less than the normal amount. Arsenic acts like silicon, the iron being kept in the state  $\alpha$ . It had no appreciable effect on the points  $a_2$  and  $a_1$  in the specimens examined.

6. *Tungsten* (four specimens, due to the same origin as the preceding). Tungsten (varying from "traces" to 1.50 per cent.) seems to cause no change in the position of  $a_3$  or the amount of heat evolved at this point. But  $a_1$  is considerably lowered if the metal has been sufficiently heated; it was lowered to 540°—530° in the specimen containing most tungsten, a phenomenon observed before in a steel of much harder character. The behaviour of tungsten is peculiar.

—P. J. H.

*On the Role of Foreign Bodies in Iron and Steel, and the Relation between their Atomic Volumes and the Allotropic Transformations of Iron.* F. Osmond. Compt. Rend. 110, 346—348. (See preceding abstract.)

THE author points out that his experiments confirm the suggestion of Roberts Austen (Phil. Trans. 179, 339—349, 1888) that the effect of the admixture of small quantities of metallic impurity with metals is related to the atomic volumes of the elements concerned.

In the following table, column I. contains the elements examined, whose atomic volume is less than that of iron (7.2), column II. those with greater atomic volume.

I.	Atomic Volume.	II.	Atomic Volume.
Carbon .....	3.6	Chromium .....	7.7
Boron .....	4.1	Tungsten .....	9.6
Nickel .....	6.7	Silicon .....	11.2
Manganese .....	6.9	Arsenic .....	13.2
Copper .....	7.1	Phosphorus .....	13.5
		Sulphur .....	15.7

The bodies in column I. (other things being equal) retard the transformation of the  $\beta$ -modification of iron into the  $\alpha$ -modification, and of hardening carbon into annealing carbon. Hence, under the same conditions of cooling, they tend to increase the proportion of the  $\beta$ -iron in the metal *and to harden it*. Hydrogen, in the form of Graham's "hydrogenium," may also be included under this head, electrolytic iron in which it is contained being very hard and brittle. Gaseous hydrogen seems to have but little effect on the critical temperatures. The bodies under column II., with larger atomic volume than that of iron, would tend either to increase or at any rate to keep the temperature of transformation of  $\beta$ -iron into  $\alpha$ -iron at the normal point, and also (with the exception of tungsten) raise the temperature at which hardening carbon is transformed into annealing carbon. Hence they would tend, like annealing, to render the metal softer and more malleable; but this effect is sometimes masked by the properties of the admixed metal itself. We may say that admixed metals, if their atomic volume be low, tend to keep iron in the molecular modification of low atomic volume; if their volume be high, tend to keep it in the modification of high atomic volume.

Carbon, though obeying the general law, exerts a peculiar influence on iron, owing to the transformation which it undergoes at a certain temperature, and the existence of which is undeniable; hence its importance in the metallurgy of iron. (See this Journal, 1889, 75.)—P. J. H.

*Hadfield's Manganese Steel.* H. Le Chatelier. Bull. Soc. d'Encouragement l'Ind. Nat. 1890, 22—26.

This is a report made to the *Société d'Encouragement* by Le Chatelier on behalf of the *Comité des Arts Chimiques*, completely bearing out all that Hadfield claims for his alloy. The results of a series of experiments made for the purpose of direct verification of the properties of the alloy are exhibited in the following table:—

#### COMPOSITION OF THE ALLOY.

Mn = 13.9 per cent. C = 1.36 per cent.

##### (1.) TENSILE STRESS.

Dimensions of test-piece.—Length, 80 mm. Diameter, 8 mm.

	Breaking Load in Kilos. per sq. mm.	Elongation Per Cent.
Tested as forged .....	81.3	1.23
Heated to a red heat and oil-toughened .....	80.9	18.9
Heated to a yellow-heat and water-toughened .....	91.2	35
Heated to a yellow heat and toughened in a refrigerating mixture .....	106.9	51.8

##### (2.) BENDING STRESS.

Dimensions of test-piece.—70 × 24 × 9 mm.

	Interior Angle at Fracture.
Tested as forged .....	172°
Heated to a red heat and toughened in oil .....	154°
Heated to a red heat and toughened in water .....	Folded completely.
Heated to a yellow-heat and toughened in water .....	Showed deep cracks on bending double.

—S. B. A. A.

#### *The Treatment of Waste "Pickle."*

THE treatment of galvanisers' waste pickle—a most serious matter for West Bromwich, Wolverhampton, and Great Bridge in particular—has been recently made the subject of experimental tests with a view of neutralising its deleterious effects. Thomas Turner, of Mason's College, has patented a process which promises to achieve the desired ends, and which has been for some little time past in operation at the works of Walker Brothers, Walsall and Netherton (this Journal, 1889, 780). The principle of the process is simple in the extreme. The waste liquor is merely boiled down to dryness, and the solid residue heated to low redness. Oxide of iron remains in the furnace, while free hydrochloric acid distils off, is condensed, and can be used over again *ad infinitum*. But though the idea is thus simple, the practical application of it was a matter which involved costly experiments, extending over many months. The difficulties to be overcome were very great, since the liquor contained so much free acid that to use any metal vessel was quite impossible; nor could it be contained, when at boiling heat, in any kind of brick or stone evaporating-pan. At the same time it yielded, on evaporation, such a large quantity of solid residue that the bottom of any vessel used became covered with a thick deposit after a few hours' working, and this deposit was so hard that it could be removed only by means of a sledge-hammer and a crow-bar. Even this was not all. The ferrous chloride, when heated in the presence of air, formed a considerable amount of ferric chloride, which, volatilising freely, contaminated the recovered acid. All these difficulties have at length been overcome, and the process has been in successful operation for six months, and has been proved on the large scale to entirely do away with the waste "pickle," and what is even more remarkable, to yield a clear profit after paying all working expenses.

The ferrous chloride and the waste liquor are heated in one and the same furnace by the reverberatory principle. Much depends upon the regular introduction and distribution of the liquor. The corrosive action of the free acid is avoided by leaving on the brick floor of the retort a coat of the thick deposit above mentioned; the formation of ferric chloride is checked by roasting the residue inaccessibly to air; and the method of working by heat from above prevents the deposit from caking beyond such a depth as is desired. The distilled acid is condensed in a tall stack of special construction; and the oxide of iron remaining is raked out of the furnace in the state in which it is commonly known as "blue billy," and is of use in puddling operations for "fettling." As a result of experience it is found that the furnaces will work three months without stoppage, that they use only 4 cwt. of fuel to completely treat a ton of waste liquor, that the acid recovered is perfectly suitable for using over and over again, and that the oxide of iron recovered has a value which goes a long way towards paying for the fuel used.

#### PATENTS.

*Improvements in the Treatment of Complex Gold and Silver bearing Ores and other Substances, and the Recovery of Metals therefrom.* H. Hutchinson. Eng. Pat. 14,400, October 6, 1888. 6d.

COMPLEX gold and silver "sulphurets, arsenurets," &c., or artificial products such as matte and regulus, are treated with an alkali or alkaline earth, or with the carbonates of these latter, either before or after calcination, whereby "sickening or flouring" of the mercury used in the amalgamation process is prevented, or loss of chlorine, bromine, &c. in the solvent processes. In one modification of the process the ore is calcined, either with or without addition of common salt, care being taken not to decompose the sulphates which are formed by oxidation of the sulphur. The calcined ore is then treated with water to remove soluble sulphates and chlorides, leaving a residue of silica, oxide of iron, sulphate or chloride of lead, and free gold. On treating this residue with an alkali or alkaline carbonate the lead salts are decomposed, and their "flouring" effect prevented. The

oxidation of the finely-divided iron derived from the stamps is one of the causes of the "flouring" of mercury.

—H. K. T.

*An Improved Method of Lining Barrels or other Vessels to resist Acids for use in extracting Metals by Chlorination or similar Process from their Ores.* T. Bell, Lincoln. Eng. Pat. 2350, February 9, 1889. 4d.

VESSELS of wood or iron are lined with lead, the lead is coated with gutta-percha, which is again coated with lead. The outer lead coating may be omitted.—H. K. T.

*Improvements in the Treatment of the Calcined Products or "Small Mine" of certain Iron Ores, Ironstone Mines and Shale, and the Manufacture of the same into Blocks for the better Extraction of Iron therefrom.* A. Hodgkinson, Peacock's Hey. Eng. Pat. 4537, March 15, 1889. 4d.

"SMALL mine," the waste product left on the mine-hearths in the calcining of various ironstones in Staffordshire, is compressed into blocks and fired, in order to render it fit for smelting. Sometimes the powdered material is riddled before compression.—H. K. T.

*Improvements in Machinery or Apparatus for the Extraction of Gold and Silver from their Ores by Amalgamation.* T. R. Jordan, London. Eng. Pat. 4719, March 18, 1889. 11d.

A NUMBER of circular dishes of amalgamated copper are mounted on a vertical spindle and made to rotate. Beneath each dish is a tray sloping towards the centre where it is perforated. The auriferous sand, when charged into the uppermost dish, is forced by centrifugal force up the edges of the dish with considerable friction, thus ensuring perfect contact with the amalgamated surface. It then falls on to the sloping tray and passes to the next dish, and so on to the bottom. There it falls into a well, and is kept in agitation by a stream of water. Mercury is placed in the dishes or in wells formed on the peripheries of the fixed partitions.—H. K. T.

*Improvements in Means or Apparatus for the Purification of Molten Tin or its Alloys.* D. Owen, Morriston. Eng. Pat. 5037, March 23, 1889. 8d.

THE molten tin or alloy is made to pass through a "reticulate or filtering masses formed of assemblages of plates, wire, shot, or woven wire work, fibre, or other forms of iron or other metal or suitable refractory material," for the purpose of removing "scruff" before passing to the tinning pot.—H. K. T.

*Improvements relating to the Drying and Calcination of Ores or other Substances, and to Apparatus therefor.* W. Butlin, Wellingborough. Eng. Pat. 5869, April 5, 1889. 8d.

AIR heated to a temperature of from 900°—1,000° F. is used for drying and calcining ores, limestone, and other substances, to prepare them for the smelting furnace. A furnace or kiln is employed, having a perforated chamber, of cylindrical or other form, built up of boiler plates or of cast metal cylinders firmly united, &c., into which air passes, heated by the waste heat from the smelting furnace. The heated air then passes from the perforated chamber into the furnace or kiln.—E. G. C.

*An Improved Method for and Apparatus for Separating Liquid containing Precious Metal from Ores treated by Wet Processes.* T. K. Rose and D. Dennes, Denver, Colorado, U.S.A. Eng. Pat. 6026, April 8, 1889. 8d.

THIS method, which is applicable to any of the wet chlorination processes, consists in enclosing the material to

be leached in closed filtering vats or tanks, and forcing air, steam, water, or other fluid into these vessels, so as to drive the solution under pressure (usually about 60 lb.) through a bed of filtering material.—E. G. C.

*Improvements relating to the Recovery of Soda from Slags containing the same.* "The Alkaline Reduction Syndicate, Limited," and A. B. Cunningham, Hebburn-on-Tyne. Eng. Pat. 7733, May 8, 1889. 4d.

THE slag remaining after the preparation of metallic sodium or after the reduction of metallic ores by the use of an alkali, is run, whilst in a molten condition, directly into water, solution at once taking place. If the slag be run into milk of lime then any carbonate of soda will be at once causticised and a solution of pure caustic soda produced.—S. G. R.

*A New or Improved Alloy.* A. M. Clark, London. From "La Société en participation Bourbouze et Compagnie," Paris, France. Eng. Pat. 13,718, August 30, 1889. 4d.

AN alloy of 100 parts of aluminium with 10 parts of tin, possessing a density 2.85 and an index of specific heat 0.180, together with the characteristic properties of pure aluminium, viz. "strength, lightness, inoxidability, ductility," &c.—E. G. C.

*An Improved Process or Means for extracting Precious Metals from their Ores.* D. Deunes. Eng. Pat. 19,621, December 6, 1889. 6d.

THE ore passes through a crushing mill, then through a muffle furnace, where it is roasted by gaseous fuel. It next passes into a vessel rotating on hollow trunnions, where it is treated with bleaching powder and sulphuric acid. Any excess of chlorine is removed by blowing air or steam through one of the trunnions, the gases passing out through the other one and thence through slaked lime or other absorbing materials. The liquid contents of the vessel then pass through filtering beds and finally through layers of sulphides.—H. K. T.

ERRATUM.—Owing to a misprint in the original journal the conclusion of the last sentence of first abstract on second column, page 296, has been made to read " $\text{Fe}_2\text{Fe}_3\text{C}$ ,  $\text{Fe}_3\text{C}$ ," instead of " $\text{Fe}$ ,  $\text{Fe}_2\text{C}$ ,  $\text{Fe}_3\text{C}$ ," as intended by the author.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

*Experimental Researches in the Reduction of the difficultly-reducible Metals.* A. J. Rogers. Reprinted from Proceedings of the Wisconsin Natural History Society, 1889. J. Franklin Inst. 1889, 98, 486—487.

THIS paper gives the results of experiments on the electrolysis of sodium and aluminium salts at high temperatures. An average of 61 per cent. of the theoretical yield of sodium can be obtained by electrolysis from the fused chloride, the yield being 5—6 lb. of sodium per electrical horse-power in 24 hours. Alloys of sodium with tin and lead were prepared by making these metals the negative electrodes in the electrolysis, either of sodium chloride alone, or of the latter mixed with cryolite. They do not attack silicious crucibles so rapidly as pure sodium. Aluminium can be prepared by heating the alloys with cryolite, or with the double chloride of aluminium and sodium. The yield was 1 lb. of aluminium per electrical horse-power in 24 hours.—H. K. T.

*On the Ratio between the Electric and Thermal Conductivities of Metals.* A. Berget. *Compt. Rend.* **110**, 76—77.

THE author has determined to measure the electric conductivity  $k$ , and the thermal conductivity  $c$ , of copper, zinc, iron, tin, lead, antimony, mercury and brass, at temperatures between  $0^\circ$  and  $30^\circ$ . The ratio  $\frac{k}{c}$  varies from  $1.6 \times 10^3$  to  $1.8 \times 10^3$ . The temperature-coefficient of the two conductivities is also different. Hence they can only be regarded as approximately proportional to one another.

—P. J. H.

*On the Electrolysis of Alumina and Aluminium Fluoride in the Fused State.* A. Minet. *Compt. Rend.* **110**, 342—343.

THE author has made a large number of experiments for the purpose of obtaining aluminium by electrolysis on a large scale. He gives the following details of 22 experiments: (1) Nature of cathode (iron or carbon); (2) Duration of experiment (varying from 7 to 24 hours); (3) Current intensity (from 90 to 1,200 ampères); (4) Difference of potential at electrodes (from 4 to 6.35 volts); (5) Weight of metal obtained (0.363 to 5,440 kilos.); (6) Percentage of theoretical yield (55 to 82 per cent.) No further account of the process is given. The experiments were carried out at the works of MM. Bernard, at Creil.—P. J. H.

#### PATENTS.

*Improvements in the Manufacture of Incandescence Electric Lamps.* J. W. Edmundson, Gateshead-on-Tyne. Eng. Pat. 3353, February 25, 1889. 4d.

TO prevent lamps from blackening and to obtain uniformity, the filaments are coated with chromium, in some such way as the following:—They are painted with chromium chloride dissolved in spirits of wine, dried, and then raised to very bright incandescence in a vessel exhausted of air as completely as possible. The chloride is reduced and the metal deposited, the filament getting a smooth grey surface and a lowered resistance. The operation may be repeated if necessary.—E. T.

*An Improved Process for the Manufacture of Aluminium and Apparatus therefor.* J. L. E. Daniel, Westminster. Eng. Pat. 4169, March 9, 1889. 11d.

IN this process aluminium is produced by electrolysis the double chloride of aluminium and sodium, and means are provided for maintaining a constant and continuous replenishment or regeneration of the bath with chloride of aluminium, as fast as it loses the same while undergoing electrolysis. For the production of the chloride of aluminium, an upright retort is filled with alumina and carbon, and is heated while dry chlorine is caused to pass through it.—E. G. C.

*Improvements in the Electrolytic Process of Obtaining Copper, Zinc, and Tin.* H. A. Seegall, Berlin, Germany. Eng. Pat. 4871, March 20, 1889. 6d.

THE material to be treated, containing copper with zinc or tin, is first lixiviated with a moderately concentrated solution of ferric chloride, slightly acidulated. Proto-chloride of iron, and the chlorides of zinc or tin, are formed and pass into solution, while cuprous chloride remains suspended. The whole is filtered, and the filtrate treated electrolytically for zinc or tin. The deposit of cuprous chloride is mixed with copper borings, &c., and again lixiviated with a concentrated solution of the ferric chloride, also acidulated with at the same time the addition of calcium or sodium chloride, to hold the cuprous chloride in solution. This solution is then treated electrolytically for its copper. The various liquids to be electrolysed pass from cathode cell to

cathode cell of a series of baths, till the metal is removed, and then through the anode cells of the same baths, to be oxidised again, being then used for lixiviating fresh masses of the substance.—E. T.

*Improvements in the Method of and Means for Electrolysis of Substances in a State of Fusion.* M. Kiliani, Xenhausen, Switzerland. Eng. Pat. 6745, April 20, 1889. 8d.

IN order to keep the temperature of the fused mass as low as possible, and also to keep the crust which is formed on the surface of the mass constantly stirred back into the active path, the positive electrode is so arranged that it can be rotated either concentrically or eccentrically about its axis. The positive electrode is also so arranged that it can be raised from or lowered into the fused mass as it burns away.—B. T.

*Improvements in Electric or Galvanic Elements or Cells.* P. Schoop, Zurich, Switzerland. Eng. Pat. 7719, May 8, 1889. 6d.

IN order to convert the electrolytes of batteries into a solid or semi-solid state "water-glass" (i.e., silicate of soda or potash) is added in suitable proportions, or, instead of water-glass, a solution of sulphate of iron, either alone or mixed with hydrate of soda or potash, or with water-glass, may be added.—B. T.

*An Improved Process and Apparatus for the Continuous Extraction of Gold and Silver from Substances containing the same by the Agency of Chlorine.* J. A. H. T. Ranft, Sydney, N.S.W. Eng. Pat. 19,944, December 11, 1889. 8d.

CHLORINE is liberated by electrolysis from a solution of sodium chloride in contact with the gold or silver or the substances containing the same. The chlorides produced are immediately split up electrolytically, the chlorine being set free at the anode and regenerated for further use, and the metallic elements deposited upon the cathode. There are ten claims in connexion with this process, and the apparatus therefor.—E. G. C.

*Improved Battery Plates for Storage Batteries.* A. E. Woolf, New York, U.S.A. Eng. Pat. 20,911, December 31, 1889. 8d.

A LONG plate of lead is pasted with lead oxide, and then rolled tightly upon itself in a close scroll. This is then heavily pressed, so as to convert the almost circular cross section into an elongated one. Slices are now cut off the end, each slice forming a complete plate. This is encircled by a strap of hard rubber, which being wider than the plate is thick, not only serves to hold it together, but acts as a separator as well.—E. T.

*Improvements in Secondary or Storage Batteries, and in the Manufacture of Plates therefor.* H. H. Lake, London. From P. H. Alexander, New York, U.S.A. Eng. Pat. 302, January 7, 1890. 8d.

THE inside of the battery case is lined with rubber, or some such material, in which grooves have been moulded or rolled. Into these grooves the individual plates slide, and the compartments thus formed are rendered quite water-tight by compressing the rubber from one end. One side of each plate is thus positive and the other negative, there being as many cells—all of course in series—as there are compartments. Moreover, the inventor packs his plates with dry oxide, then puts them in a pile, separated from one another by felt soaked with dilute acid, and passes a current through the whole till formed.—E. T.

*Improvements relating to Secondary Batteries.* H. H. Lake, London. From P. H. Alexander, New York, U.S.A. Eng. Pat. 303, January 7, 1890. 8d.

THE battery-box is made of some suitable material, such as hard rubber, and fastened to the outside are strips of metal from the terminals of the cell, so arranged that should the temperature of the cell rise above a certain point, the consequent expansion of the material of the box brings these metal strips into contact and short-circuits the cell through a safety cut-out, which cut-out is fused by the passage of the extra current and cuts the cell out of circuit. A second device for cutting out a cell which is giving off gas freely is a U-tube filled with the electrolyte and inverted in the liquid. As the gas is evolved in the cell some of it enters the U-tube and displaces the liquid in it so that it rises bringing two strips of metal into contact and cutting out the cell by means of the fuse arrangement described above.

—B. T.

*Improvements relating to Secondary or Storage Batteries.* H. H. Lake, London. From T. Ewing, New York, U.S.A. Eng. Pat. 1094, January 21, 1890. 6d.

THE inventor packs the plates with *Massicot* (litharge) since the active material obtained from this has, he states, the same rate of expansion and contraction as the lead support itself. There is therefore no buckling or deformation of the plates. The litharge may be applied as a paste, or packed dry into the plates by pressure. In the latter case immersion of the plates must not go on at a more rapid rate than six inches a minute, else disintegration will take place. The cells are stated to have a larger storage capacity by this method of forming.—E. T.

*An Improvement in Galvanic Batteries.* C. A. Hitchcock, London. From W. Burnley, North East, Pennsylvania, U.S.A. Eng. Pat. 1110, January 21, 1890. 6d.

THE containing-vessel of this battery is a cylinder of zinc closed at one end and serving as the positive electrode. A core of suitable size and material is placed in position in the zinc cylinder, leaving an annular space around it, and into this space is poured the following mixture in a semi-fluid state:—Sal-ammoniac, 1 part; chloride of zinc, 1 part; plaster of Paris, 3 parts; water, 2 parts; and a vegetable material, such as flour, 1 part. When this mixture has set, the core is withdrawn, and a carbon cylinder inserted, also leaving an annular space around it. This space is filled with sal-ammoniac, 1 part; chloride of zinc,  $\frac{1}{10}$ th part; peroxide of manganese, 3 parts; pulverised carbon,  $3\frac{1}{2}$  parts; water, 2 parts. The top of the cylinder is then sealed in with a compound such as bitumen.—B. T.

*Improvements relating to Storage Batteries or Accumulators.* H. H. Lake, London. From G. A. Johnson, Boston, U.S.A. Eng. Pat. 1495, January 28, 1890. 6d.

EACH electrode is built up of two corrugated plates, so put together that there is a series of horizontal channels formed of somewhat elliptical-shaped section. Into these the active material is packed, being placed in communication with the electrolyte outside by very numerous small perforations in the plates themselves. The electrodes are insulated and supported by vertical rods passing downwards between them.—E. T.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

*The Constituents of Iceland Moss.* A. Hilger and O. Buchner. Ber. 23, 461—464.

KNOX and SCHNEIDERMAN (Ann. Chem. Pharm. 55, 164) have examined two of the constituents of Iceland moss (*Cetrarea islandica*) (see under XX., page 544.) lichestearic acid and cetraric acid. These have been further studied by the authors. Lichestearic acid is best extracted from the powdered moss by means of petroleum spirit, and forms, when purified by recrystallisation, a voluminous crystalline mass melting at 120°, and soluble in the ordinary reagents with the exception of water. The alkali salts of the acid are soluble, those of the other metals insoluble in water, but none of them could be obtained crystalline. Analyses of the silver, barium and lead salts, of an acid chloride and also of the free acid, are given, from which the formula  $C_{43}H_{76}O_{13}$  appears probable, the acid being dibasic,  $C_{41}H_{74}O_9(CO.OH)_2$ .

Acetyl chloride is without action on the free acid; on oxidation with potassium bichromate and sulphuric acid, carbon dioxide is evolved and capric acid formed.

Cetraric acid forms a white amorphous powder, with a bitter taste, almost insoluble in water. It dissolves in alcohol, but is difficultly soluble both in ether and in petroleum ether. At 200° it decomposes before melting. Analyses of the acid and of its barium and silver salts point to the molecular formula  $C_{30}H_{50}O_{12}$ , and to the dibasicity of the acid.—C. A. K.

## PATENTS.

*Method of Extracting Pure Neutral Grease from Wool and the like.* C. Lahusen and C. Feuerlein, Delmenhorst, Germany. Eng. Pat. 11,383, July 16, 1889. 6d.

PURE neutral wool grease has hitherto been obtained from the sludge thrown down by treating wool washings with sulphuric acid, by more or less troublesome methods. The present plan consists in mixing the sludge (wet or dry) with a "five-fold quantity" of a solvent such as "benzine, bisulphide of carbon, ether, or chloroform, or a mixture of these liquids, at 50°—70° C. A solution of some "water absorbent material" e.g., the chloride of sodium potassium or magnesium or sodium sulphate, is then added in quantity equal to about half the liquid previously used, and the whole well mixed. The mass separates into two layers on standing, the one consisting of a solution of wool grease in carbon, disulphide, ether, &c., the other of the soapy impurities and metallic salts. The former is run off, distilled, and the wool grease obtained, the latter worked up into soap, or otherwise, by known methods.—B. B.

*Improvements in Lubricants.* J. L. Wade, London. Eng. Pat. 540, January 11, 1890. 4d.

A MIXTURE is made of crude glycerin, mineral oil and castor oil in proportions varying with the character of its proposed use, by heating it with close steam in a boiler and causing a rush of air through it when it has reached a suitable temperature by exhausting the air-space above the surface of the liquid, and permitting the entrance of air by an inlet pipe at the bottom, which both mixes and dries the oils.—B. B.

### XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

#### PATENTS.

*Improvements in the Production of the Compounds for the Manufacture of the Soles and Heels of Boots and Shoes, the same being applicable to other useful Purposes.* A. A. Blandy, London. Eng. Pat. 3591, February 28, 1889. 6d.

THE artificial leather is composed of asphalte, mineral pitch, colophony or black resin, gypsum, gutta-percha, and sulphide of antimony. A harder compound for the heels of boots and shoes is prepared from the same ingredients with the addition of some sulphur, but the proportion of gutta-percha is smaller. The most suitable proportions are given in the specification.—E. E. B.

*The Manufacture or Production of an Improved Material or Compound adapted for use as a Substitute for Ivory, Horn, Whalebone, India-rubber, Gutta-percha, and other Materials, also as a Coating or Varnish for Waterproofing and other Purposes.* F. Greening, Uxbridge. Eng. Pat. 5344, March 28, 1889. 6d.

COTTON combings, paper, esparto grass, or rags, are treated with a mixture of nitric and sulphuric acids. The excess of acid is drained off and the material is placed in a warm atmosphere for one hour. It is then washed with water and transferred to a bath of sodium chloride and ammonia alum. After again washing and drying it is dissolved in a mixture prepared as follows:—Lead acetate and lime are distilled and the product is mixed with fusel oil. The mixture is redistilled after the addition of phosphoric chloride or carbonate of potash. The distillate mixed with absolute alcohol constitutes the solvent.

The plastic mass obtained by the action of the solvent on the nitro-compounds, may be moulded into any desired form. A thin solution can be used as a varnish.—E. J. B.

*Improvements in obtaining Yellow Pigments.* J. Macfarlane, Barnhead. Eng. Pat. 7156, April 30, 1889. 4d.

CARBONATE of lime is mixed with a solution of ferrous sulphate and a yellow precipitate is obtained, consisting of hydrated oxide of iron together with sulphate of lime, and the excess, if any, of carbonate of lime.—E. E. B.

*Improvements in Fabrics.* A. J. Boulton, London. From C. Coste, Paris, France. Eng. Pat. 7967, May 13, 1889. 4d.

“AN improved article or fabric mainly consisting of pure floss silk, which by being coated with india-rubber and like substances of any colour or shade, acquires an appearance similar to that of leather, and is adapted to replace both leather and waterproof india-rubber stuffs imitating leather.”—H. S.

*Improvements in the Manufacture of Artificial Ivory or Ivory Substitutes.* A. and S. de Pont, Paris, France, and H. J. and J. H. Storey, Lancaster. Eng. Pat. 9267, June 4, 1889. 6d.

See under XIX., page 540.

*An Improvement in the Manufacture of Oil Varnish.* H. Noerdlinger, Stuttgart, Germany. Eng. Pat. 9563, June 8, 1889. 4d.

A NON-VOLATILE oil is heated with a saturated salt of resin acid, oleic acid, or another fatty acid. This mixture is allowed to cool, and the supernatant clear liquid mixed with from ten to a hundred volumes of a drying oil, such as linseed oil.—E. E. B.

*Improvements relating to the Covering of various Articles with Xylonite or Celluloid.* E. A. Bluemel, Bow. Eng. Pat. 17,496, November 4, 1889. 4d.

A TUBE of xylonite of smaller diameter than the article to be covered is placed in boiling water or steam and stretched over a heated mandril. It is then plunged in cold water and the mandril removed. The article is then inserted and plunged with its covering of xylonite into boiling water for about 30 seconds, until the tube has contracted and fits closely to the article. They are again plunged into cold water, and, if necessary, the ends are plugged with similar pieces of xylonite.—E. J. B.

### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

#### PATENTS.

*A New or Improved Adhesive Cement and Process of Manufacturing the same.* W. P. Thompson, Liverpool. From K. Korenar and F. Zwickler, Karolinenthal, Austria. Eng. Pat. 2197, February 11, 1889. 4d.

THIS cement, suitable for joining or repairing leather, hemp, or india-rubber hose pipes, is prepared by dissolving about 50 parts by weight of gutta-percha in a liquid mixture of 120 parts by weight of “benzine,” 80 parts “sulphuret of carbon,” and 20 parts of turpentine, removing the surface scum from this solution and mixing it with a second batch of a similar solution whilst in a boiling state. The liquid mixture obtained is drawn off into suitable receptacles, and kept hermetically sealed.—B. H.

*Improved Method of Manufacturing Artificial Leather or Leather Boards made from Hard Sole Leather Cuttings or other Leather Scraps and various Fibrous Substances.* H. R. Mims, Maidenhead. Eng. Pat. 6103, April 9, 1889. 4d.

LEATHER cuttings or scraps are boiled in an alkaline or acid solution till dissolved. In practice a solution of sulphuric acid containing from 5 to 20 per cent. answers well. The fibrous substance used, such as leather, hemp, manilla, or jute, is mixed with the solution of leather cuttings in an ordinary heating engine at a “temperature of 110°–180°.” When all is reduced to a pulp of the required consistency, it is passed through a suitable machine and made into sheets or boards. The sheets or boards are then engraved with any design by suitable machinery.—B. H.

*Improvements in the Manufacture of Cement for joining Wood, Stone, and other Materials.* S. Hindley and G. R. Mackenzie, London. Eng. Pat. 7943, May 11, 1889. 4d.

THIS cement is prepared by soaking glue in water for about 12 hours, and then adding to the glue, after melting it, a mixture of white lead and cement, together with a solution of resin in methylated spirit or mineral oil. The following proportions give good results:—Dissolved glue, 84 lb.; Parisian cement, 9 lb.; white lead, 9 lb.; resin, 6 lb.; methylated spirit, 4 lb.—B. H.

*Improvements in the Process and Means for Dyeing Hides.* J. Kristen, Brunn, Austria. Eng. Pat. 8191, May 16, 1889. 8d.

See under VI., page 500.

*An Improved Glue or Cement.* G. Rothel, London. Eng. Pat. 556, January 11, 1890. 4d.

THE glue is composed of the following ingredients in about the following proportions:—Scotch glue, 6 lb.; rosin, 2 lb.; gutta-percha, 2 oz.; caoutchouc, 1 oz.; wood ashes, 2 oz.; red lead, 4 oz.; bisulphide of carbon, 1 oz.; zinc ash, 2 oz. The glue is first boiled, to which a solution of the rosin in carbon bisulphide is added. The gutta-percha and caoutchouc are then dissolved in carbon bisulphide and added to the glue and rosin, and the mixture is boiled for two hours.

The red lead, wood ashes, and zinc ash are next added, and the whole mixture boiled for three hours with continual stirring. When required for use the glue is liquefied by heat.—B. II.

## XV.—AGRICULTURE, MANURES, Etc.

*Value of Thomas-slag Phosphoric Acid compared with Soluble Phosphate and Bone-Meal impoverished of Lime.* E. Güntz. Ber. u. d. Thätigkeit d. agrikultchem. Versuchsstat. Pommritz, 1888, 11—17; Bied. Centr. 29, 86—87.

ANIMAL charcoal superphosphate (spodium-superphosphat) containing 13·81 per cent. of soluble phosphate; Thomas-slag (93·6 per cent. of fine powder) containing 50·8 per cent. of CaO and 24·11 per cent. of  $P_2O_5$ ; and bone meal, consisting of 92 per cent. of fine bone meal, and containing 30·3 per cent. of  $P_2O_5$ , and 1·49 per cent. of nitrogen, were employed in proportional quantities along with sodium nitrate on potatoes (Saxon onion potato). Thomas-slag gave the best result, then the bone meal, the plots without phosphate manure being poorest. There was much rain in June.—D. A. L.

*Relative Manurial Value of Phosphate, with special reference to Thomas-slag, Bone-Meal, Peruvian Guano, and Coprolite Powder.* Prize Essay by G. Marek. Bied. Centr. 19, 142—144.

Numerous plants, including oats, peas, mangolds, sugar-beet, potatoes, carrots, barley, buckwheat, summer wheat, and beans were cultivated on a great variety of soils, such as clayey, loamy, sandy, humus, marshy and calcareous loamy soils, also rich, poor, and intermediate loams, and a clayey loam, the plant being selected to suit the soil. All received the same quantity of nitrogen, potash, lime, and phosphoric acid, but the form in which the last two were given was varied. During the progress of the experiments records were kept of the temperature of the air, of the cloudiness, of the direction of the upper (cloud) air currents, and of the precipitation. The warmth of the soil at depths of 5, 10, 20, 30, 40, 50, 60, 70, 80, and 100 cm., and the temperature of the original soils from which the experimental ones were taken to a depth of 1 cm. Some of the soils were sifted. The manuring varied as to periods of sowing and the quantity sowed, and for comparison, plots were left without manure. All observations were taken into consideration when discussing the results, and the experience gained in one year's experimenting was made use of in the succeeding year. Results are recorded under many different headings. The following are some of the general data relating to the value of phosphates:—

Crop.	Phosphates in Order of Merit.	Percentage yield above Unmanured.	
		Observed.	Mean.
Winter cereals .....	Thomas-slag .....	..	29
" .....	Bone-meal .....	..	23
" .....	Coprolite powder ..	..	22
" .....	Peru guano .....	..	10
Summer cereals .....	Peru guano .....	0·3—37	21
" .....	Coprolite powder ..	6·0—30	15
" .....	Bone-meal .....	0·5—26	12
" .....	Thomas-slag .....	1·0—19	10
Hoed crops .....	Peru guano .....	9—53	33
" .....	Bone-meal .....	12—47	27
" .....	Thomas-slag .....	8—26	24
" .....	Coprolite powder ..	7—41	23

After-action was investigated on the following kinds of soil:—

1. Calcareous loam.....after sugar beet.
2. Loam....." "
3. Sandy soil....." potatoes.
4. Clay....." mangolds.
5. Marshy soil....." potatoes.
6. Humus soil....." carrots.
7. Rich loam.

The crops selected were potatoes and sugar-beet; they were sown a year after the previous harvest, and were harvested when mature. Potatoes were grown on soils 1—6. No after-action was evident on the clay and marshy soils; three of the soils showed after-action, and one in some instances. The after-action of the different phosphates on potatoes on these soils is shown in the following results:—

—	Observed.	Mean.
	Per Cent.	Per Cent.
Bone-meal .....	0—13·7	9
Coprolite powder .....	2·2—16·2	8
Thomas-slag .....	—18·0—14·2	1
Peruvian guano.....	—12·6—5·6	—2·5

The rich loam served for the sugar-beet experiments and the after-action of the individual phosphates in this case was as follows:—

—	Percentage Yield above Unmanured.	
	Observed.	Mean.
Bone-meal .....	1·3—54·8	30
Thomas-slag .....	1·0—63·1	27
Coprolite powder.....	11·0—49·9	24
Peruvian guano .....	—10·0—51·0	18

The monograph terminates with a summary.—D. A. L.

*Influence of the Degree of Subdivision on the Activity of Thomas-slag on Barley.* Ulbricht. Der Landbote 1889, 833—835.

Pot experiments were conducted:—(1.) In sand to which was added per 4,000 grms. of sand, 0·2235 grm. of potassium chloride, 0·096 grm. of magnesium sulphate, 1·3120 grm. of calcium nitrate, 0·1596 grm. of ferric hydrate, and 11 grms. of humus acid. (2.) In marshy soil containing per cent. dry soil:—N, 3·39;  $K_2O$ , 0·29;  $Na_2O$ , 0·22;  $CaO$ , 4·06;  $MgO$ , 0·15;  $P_2O_5$ , 0·11;  $SO_2$ , 0·5; sand,  $Al_2O_3$ , &c., 13·98; loss on ignition 76·14, and which received 0·4784 grm. of potassium chloride; the moistness during the experiment amounted to 100 to 150 per cent. of the dry marsh soil. The barley seeds were covered with a 2-centimetre layer of glass sand. Basic slag of various degrees of fineness, as indicated in the following table, were added to the pots, the quantities being:—0·1417 of phosphoric acid as monocalcium phosphate, twice that quantity in the other direct experiments, and six times that quantity in the additional C and G experiments.

The weights are in grms. and are in all cases from three pots. The results show the efficiency of the slag in marshy soil for barley, and that slag in fine sub-division is about half as active as monocalcium phosphate (superphosphate). The larger dressings of slag produced no decisive result.

—D. A. L.

For Table see next page.

Manuring and Condition of the Thomas-Slag.	Sand.		Marshy Soil.	
	Grain.	Straw, &c.	Grain.	Straw, &c.
No slag.....	.. ..	.. ..	1.03	20.60
Monocalcium phosphate .....	21.54	30.80	.. ..	.. ..
A. Commercial slag, 22.24 per cent. of $P_2O_5$ , 75.9 per cent. "fine powder" .....	26.35	30.62	51.33	64.
C. Grains of 0.75—1.0 mm. diameter, 20.35 per cent. of $P_2O_5$ , 5.15 per cent. of "fine powder" .....	13.92	17.83	27.41	28.54
F. Grains of 0.25—3 mm. diameter, 20.35 per cent. of $P_2O_5$ , 3.75 of "fine powder" .....	22.11	23.21	39.41	39.15

—D. A. L.

*Direct Assimilation of Ammonia by Plants.* A. Muntz.  
Jour. d'agric. prat. 1889, 671–673.

BEANS, field beans, maize, barley, and hemp, were successfully cultivated by the author under the following circumstances:—The soil was washed free from nitrates, mixed with ammonium sulphate, and sterilised at  $100^{\circ}\text{C}$ .; whilst the seeds were dipped into boiling water, just before sowing, to destroy adherent organisms. The plants were reared under covers consisting partly of glass and partly of linen, which whilst it prevented access of germs allowed free circulation of air, and as a further precaution, the walls were smeared with glycerol. The air in the room was moreover purified by water spray. Blank experiments showed that no nitric acid was formed in these sterilised soils, under these conditions; whereas non-sterilised soils produced an energetic nitrification. It is concluded that the plants in question can make use of ammoniacal nitrogen without the intervention of nitrification.—D. A. L.

*Natural and Metallurgical Phosphates.* L. Ravel.  
Jour. d'agric. prat. 1889, 969–973.

SUGAR-beet was cultivated on an acid moorland, and on a fine sandy soil rich in humus and containing per cent. 0.045 of  $P_2O_5$ , 0.06 of  $K_2O$ , 4.0 of  $CaO$ , 0.41 of  $N$ . The results confirm the generally accepted view as regards the special adaptability of Thomas-slag to acid soils and to those deficient in lime: consequently, in comparison with other natural phosphate, the slag showed to advantage on the first soil above mentioned, whilst on the second soil these two phosphates were practically alike financially, although the natural phosphate was more potent when used without other manure and the slag when dung and potash were also supplied. These phosphates yielded lower results when mixed together than when applied individually, and the best results were obtained in conjunction with dung and dung and potash. No benefit was derived from dressings of more than 1,000 kilos. of phosphate per hectare, therefore it is deemed superfluous to employ larger quantities.—D. A. L.

*On the Utilisation and Transformation of certain Alkaloids in the Seed during Germination.* E. Heckel. Compt. Rend. 110, 88–90.

THE author shows that the function of alkaloids in seeds cannot be merely, as has been supposed, to protect them from animals, but that they serve as a nitrogenous reserve for the young plant.

The germination of *Sterculia acuminata* (P. de Beaur) containing caffeine, *Strychnos nux vomica* (strychnine and

brucine), *Datura stramonium* (daturine), and *Physostigma venenosum* (esarine) was examined. In each case the alkaloid in the germinating structures was found to disappear rapidly, and to be replaced by other nitrogenous compounds, e.g., chlorophyll and potassium nitrate.

These results agree with the observations of Réveil (De l'action des poisons sur les plantes, Lyons, 1885) that if plants be watered with solutions of the organic poisons their seeds contain, they die.—P. J. H.

*Researches on the Culture of the Potato for Manufacturing Purposes and Forage.* A. Girard. Compt. Rend. 110, 176–179.

THE author describes experiments on a variety of potato hitherto little known in France, the *Richter's Imperator*, with which remarkable results have been obtained. The average yield of potatoes per hectare in France is 7,500 kilos.; 15,000—18,000 kilos. being regarded as excellent. Experiments carried out on the Government farm at Joinville-le-Pont with the new variety gave (1) in 1888 a yield of 33,000 kilos. per hectare, containing 17.6 per cent. of anhydrous starch; (2) in 1889, with a much better season, 39,000 kilos. per hectare, containing 20.4 per cent. of anhydrous starch.

By permission of the Government 6,000 kilos. were distributed to farmers in different parts of France. For the year 1889, 16 followed the author's prescriptions exactly, and obtained yields varying from 32,000 to 44,000 kilos. per hectare, with the percentage of anhydrous starch varying from 20.4 to 24.2 per cent.; with a mean of 36,000 kilos. of tubers and 7,900 kilos. of starch per hectare.

Seventeen farmers who neglected certain details (i.e., planted too far apart, manured insufficiently, sowed parts of tubers instead of whole tubers, dug up too early) obtained yields varying from 13,300 to 30,000 kilos. per hectare.

A diagram of the yields in different parts of France is given.

The author predicts that this solution of a problem, at which he has been working for six years, will enable France to compete with Germany in its production of potatoes and that potato spirit in France will compete with that obtained from the distillation of grain. Thus the value of the maize for the purpose of producing alcohol equivalent to the yield of this new potatoes per hectare (1) under unfavourable circumstances, (2) under favourable circumstances, would be respectively 1,157 francs and 1,612 francs. Details of the experiments are given in the *Annales Agronomiques*, 16, 5.—P. J. H.

*Experimental Cultures at High Altitudes.* G. Bonnier  
Compt. Rend. **110**, 363—365.

EXPERIMENTS were undertaken to determine by what means the necessary stock of reserve is accumulated by Alpine plants in their subterranean tissues, during the very short Alpine summer.

Since 1884 a series of experimental plantations has been established in the Alps and the Pyrenees, at heights varying from 50 to 2,300 metres. At many of the lower stations the soil used was brought down from the upper stations for the sake of more perfect comparison; and the plants experimented on at different altitudes were cuttings from the same individuals. The number of species investigated was 165.

The conclusions are summed up as follows—

With plants cultivated in Alpine regions under conditions similar, in every respect but that of climate, to those under which plants of the same species were grown at lower altitudes, it was found that—

1. The acrian stalks are more spreading, shorter, and bend down more towards the ground.
2. The flowers are more highly coloured, the leaves thicker, and of a darker green.
3. The protective tissues of the stem are more developed.
4. Owing to the greater thickness of the tissue of palisade cells, and to the abundance of chlorophyll, the assimilation by the leaves per unit of surface is greater.

This last observation shows that the smaller development of the acrian parts of plants is compensated for by the greater rate of nutrition.—P. J. H.

*Observations on the Reactions between Vegetable Soil and Atmospheric Ammonia.* Berthelot. Compt. Rend. **110**, 558—560.
